In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending August 27th, the death-rate was 20 8. Deaths reported 3,692: infants under one year of age 1,391; acute diseases of the respiratory organs (London) 160; diarrhœa 615, whooping-cough 98, scarlet fever 68, measles 58, fever 45, diphtheria 36, small-pox (Sheffield) five.

The death-rates ranged from 17.7 in Sunderland to 38.8 in Preston; Birmingham 22.4; Hull 21.2; Leeds 19.2; Leicester 19.0; Liverpool 22.9; London 18.5; Manchester 29.2; Newcastle-on-Tyne 22.9; Nottingham 19.5; Sheffield 24.7.

In Edinburgh 18.4; Glasgow 18.2; Dublin 29.3.

The meteorological record for the week ending September 10, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIESOF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 3, 1887, TO SEPTEMBER 16, 1887.

PERLEY, H. O., captain and assistant surgeon. Ordered to accompany battalion of the 23d Infantry from Fort Wayne, Mich., to Chicago, to participate in the International Military Encampment to be held in that city in October next. Par. 1, S. O 191, Headquarters Division of the Atlantic, September 8, 1887.

SUTER, WM. N., first lieutenant and assistant surgeon. Ordered to accompany battery "E," 3d artillery, from Washington Barracks, D. C., to Philadelphia, on the 14th inst., to participate in the military parade, during the celebration of the Centennial of the adoption of the Constitution, September 15, 16, and 17, 1887. Par. 3, S. O. 191, Headquarters Division of the Atlantic, September 8, 1887.

BYRNE, C. C., major and surgeon. Detailed as a member of the Army Retiring Board in Washington City, vice-Captain Washington Matthews, assistant surgeon, relieved. Par. 2, S. O. 208, A. G. O., September 7, 1887.

O'REILLY, R. M., major and surgeon. Ordered to proceed to Fort Niagara, New York, on public business, and upon completion thereof to return to his proper station, Washington, D. C. Par. 10, S. O., 205, A. G. O., September 3, 1887.

BANISTER, W. B., first lieutenant and assistant surgeon. Granted leave of absence for one month, with permission to apply for extension of one month, to take effect upon arrival at Fort Lowell, of Assistant Surgeon J. B. Girard. Par. 4, S. O. 91, Headquarters, Department of Arizona, August 29, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING SEPTEMBER 17, 1887.

ASHBRIDGE, RICHARD, passed assistant surgeon. Detached from "Constellation," and to the Naval Academy, Annapolis, Md.

AYERS, JOSEPH. G., surgeon. Detached from Torpedo Station, and wait orders.

WISE, JOHN C., surgeon. Ordered to relieve Surgeon Ayers at Torpedo Station.

CONES, SAMUEL T., medical director. Detached from Hospital, Chelsea, Mass., and placed on retired list September 17th.

BRADLEY, GEORGE P., surgeon. Leave of absence extended six months with permission to remain abroad.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING SEPTEMBER 10, 1887.

SAWTELLE, H. W., surgeon. Granted leave of absence for fifteen days, August 31, 1887.

CARMICHAEL, D. A., passed assistant surgeon. Granted leave of absence for thirty days, September 5, 1887.

FATTIC, J. B, assistant surgeon. Ordered to Cairo, Ill., for temporary duty, September 6, 1887.

DEATH.

Dr. James P. Webb, of Bridgton, Me., an eminent physician, died recently, aged sixty-four.

SOCIETY NOTICES.

NEW YORK STATE MEDICAL ASSOCIATION.— The Fourth Annual Meeting of the New York State Medical Association will be held September 27, 28 and 29, 1887, at the Hotel Brunswick, Fifth Avenue and 27th Street, New York City.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — The regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, Monday evening, October 3d, at eight o'clock. Readers: Dr. R. A. Kingman, "Anæsthesia in Normal Labor," (second paper). Dr. E. N. Whittier, "A Dissecting Mesenteric Aneurism."

CHARLES P. STRONG, M.D., *Secretary*.

OBITUARY.

ALONZO CLARK, M.D., LL.D.

Dr. Alonzo Clark, the distinguished professor, clinical teacher, and consultant, died September 13th, in his eighty-first year. He had been in feeble health for some years past, and during the last three or four years his mental powers had become more and more impaired. For three days preceding his death he was in a comatose condition. Dr. Clark was graduated from Williams College in 1828, but it was not till 1835 that he completed his medical studies at the College of Physicians and Surgeons of New York. He early took high rank as a teacher and lecturer, and the first professorship which he held was that of pathology and materia medica in the University of Vermont Medical School at Burlington. In 1848 he was called to the Chair of Physiology and Pathology in the New York College of Physicians and Surgeons, and seven years later he was made Professor of Physiology and Practical Medicine in his Alma Mater. While Dr. Clark wrote comparatively little, his career as a medical teacher and consultant was a most brilliant and successful one, and few men have reflected more honor on the American profession. He was for many years visiting physician to Bellevue, St. Luke's and other hospitals, where his clinical lectures were always largely attended, and in 1853 he was President of the Medical Society of the State of New York. He was also President of the New York Academy of Medicine and other societies. Dr. Clark never married. His funeral was held in the Madison Square Presbyterian Church on September 17th, and was attended by the Fellows of the Academy of Medicine, the Faculty of the College of Physicians and Surgeons, and many other medical men.

FOUR MONTHS EXPERIENCE IN MINOR SURGERY AT THE BOSTON CITY HOSPITAL.

BY HERBERT L. BURRELL, M.D.,
Surgeon to the Out-Patients at the Boston City Hospital.

During the last four months I have seen 1,685 new cases of minor surgery, many of them common and a few unique in character. On collating this mass of material the idea suggested itself that an instructive interchange of opinions might take place if a few personal experiences were presented to this Section.

The everyday technique of the practical surgeon is, I fear, in danger of being lost in the bold ventures of modern surgery, and if this paper leads to the development of a few practical points in the art of surgery, the writer's purpose will have been accomplished.

I shall try to select a few interesting details in the work, from the mass with which I have to deal, and will present those cases which may be of value for discussion.

ABSCESSES.

Sixty abscesses in various locations have been treated; the majority have been rendered externally aseptic by the free use of corrosive sublimate 1-2000, freely incised, and their contents evacuated; in a few cases they have been curetted, and all have had an antiseptic dressing applied. This method has been quite satisfactory, but occasionally it has been found necessary to omit the use of iodoform, owing to its irritating action producing an erythema. I feel quite sure that many abscesses have been hastened in their healing by removing the antiseptic dressing after the fifth or seventh day, and substituting an "open dressing," like carbolic or phenyle poultices, balsam Peru or chlorinated soda wash.

Of ten abscesses of the neck, four chronic abscesses that had small clearly-defined cavities with liquid contents, were treated by the use of a silver wire seton; the method employed is as follows: the surface is rendered aseptic, a needle doubly threaded transfixes the abscess from brawny edge to brawny edge, the looped thread draws through a small piece of silver wire, whose ends are caught together: this is covered with iodoform, antiseptic absorbent cotton and a firm bandage. In three days the dressing is removed, when it has been found that in all but one case that the contents of the cavity had been evacuated at the side of the wire. Contractile collodion is then painted on over the surface between the points of entrance of the silver wire; again absorbent cotton and bandage are applied, and in the course of a week the dressing and wire are removed. There results only two minute punctate cicatrices, which soon become almost imperceptible.

BITES.

One cat, one human, two horse and seven dog bites have been treated, none of which have been followed by any serious symptoms. In two of the dog bites, which were severely lacerated, the punctured wounds of the teeth were united by a free incision, that the wound might be thoroughly cleansed; in all of these cases the reparative process was very slow.

CONTUSIONS.

Forty-five contusions of various parts of the body have been treated, principally by immobilization, oakum pad compression and firm bandaging. Wet dressings were rarely used.

CRUSHING OF FINGERS, HANDS AND TOES.

Twenty-seven crushes of these members have been treated; this excludes all cases where amputations were performed. They all did well under antiseptic dressings; in fact, I can recall only three cases in which suppuration of any importance occurred, and all of these were cases in which the nail was split down to the matrix, and acted as a foreign body in the healing wound. I feel quite sure that it is better to primarily remove nails that have been split or crushed at the matrix.

FELONS.

Twenty felons have been freely incised, antiseptically dressed, and the digit returned to usefulness in a little over a month's time.

This period has been extended to ten or twelve weeks in five cases, owing to prolonged suppuration from the separation of a phalanx; in none of these cases has there been any extension in the form of lymphangitis or suppurative teno synovitis. All hands with wounds of any description have been placed upon splints.

FROST-BITES.

Ten of these cases have been treated in a very unsatisfactory fashion, possibly owing to the intrinsic difficulties attending the treatment of these cases. Carbolic acid, and balsam of Peru have been the applications used, but have had apparently no effect in hastening the reparative process.

GANGLIONS.

Eighteen cases of ganglion of the extensor and flexors of the hands have been treated. One by subcutaneous puncture, and sixteen by rupture of the sac, by pressure of the super-imposed thumbs; one I failed to rupture, and the patient disappeared. Two of the sixteen ganglia refilled and were re-ruptured. The after-treatment was compression by pad and bandage.

SPASMODIC HAMMER-TOE.

By which is meant a spasmodic paroxysmal flexion of a toe. I have met three cases of this affection; they have all occurred in young girls, who wore ill-fitting boots and were of a nervous temperament.

The affection is spasmodic, extremely painful during a paroxysm, and apparently perfectly well in the intervals. It is subjectively described as a cramp. In two of the cases it was worse at the menstrual period. A broad-soled boot and the fixation of the toe to a plantar pad of a roller bandage sufficiently large to fill out the concavity of the flexor surface of the affected toe, was found quite efficient.

HYDROCELE.

Nineteen cases have been treated by evacuation of the fluid by means of a small trocar; ten or twelve mm. in circumference. All of the sacs have refilled in from two days to three months; once the testicle was wounded, which was followed by an attack of orchitis. The opening in many cases was sealed with compound tincture of benzoin; adhesive plaster rarely remains in position over a few minutes.

PES PLANUM.

There have been six cases in young adults, which incapacitated them from labor. The affection usually manifests itself when the patient is obliged to stand or walk a great deal; the pain is very severe in character and has been referred in these cases to three points: to the inner middle surface of the sole of the foot and to the interspaces that exist between the malleoli and the os calcis.

Complete relief has been afforded most of these cases by the application of a properly fitted valgus plate. It has been sometimes necessary to carry the plate well up to the inner malleolus in order that a proper support for the arch of the foot might be gained.

SPRAINS.

Sixty-two sprains in various locations have been treated by immobilization, firm pressure by pasteboard and bandages, and in a few cases the collodion treatment has been satisfactorily used.

In a few cases where there has been but little tenderness over the joint, and a non-inflammatory œdema had existed; systematic massageing from the beginning was used with satisfactory results.

In a large number of cases of sprains, as soon as the tenderness of the tissues about the joint diminished and wrinkling of the skin occurred, the foot was systematically douched with hot water, massaged and a firm bandage applied.

TENO-VAGINITIS, OR SUPPURATION IN THE SHEATHS OF THE FLEXOR TENDONS OF THE FINGERS.

Five cases have been checked by free surgical incisions over the palmar surface of the affected digit, the incision being made in the median line of every tender joint, the flexure of the joint being carefully avoided.

Under antiseptic precautions, and with thorough immobilization, this treatment has been eminently satisfactory. In only one case did permanent contraction of the finger occur.

TENO-SYNOVITIS, OR CREAKING TENDON.

Four cases have been treated, and in all it was apparently due to prolonged use of the flexors or extensors of the arm. The treatment has been absolute rest by a splint, and in two of the cases, by the application of blisters. The arm has been returned to usefulness in from three to four weeks.

CHRONIC ULCERS OF THE LEG.

One of the most useful dressings in the treatment of ulcers is the so-called antiseptic tin dressing, for which I am indebted to my colleague, Dr. Watson. It is applicable in all cases where even compression and bandaging would be useful. The method of its application is as follows: The ulcer and its surrounding surface is rendered as nearly aseptic as possible, then iodoform is dusted upon the surface of the ulcer, a piece of antiseptic paper or silk is smoothly applied, then a piece of tin, which should overlap the margin of the ulcer at least one-half inch. Over this is applied a piece of boracic gauze, with a fenestra in the centre, and covering all; more gauze and a well-applied bandage. The dressing should not be disturbed until leaking occurs.

FROG-SKIN GRAFTING.

Seven attempts have been made to graft the skin from a frog's abdomen on to a granulating surface. One has been completely successful, two have been partial successes, while the rest have been failures. That success is possible is, I feel assured, and the failures have been errors in technique or from other untoward circumstances.

VARICOCELE.

Twelve cases have been fitted with suspensory bandages, with complete relief to the dragging, sickening pain so constantly complained of.

In one case the patient had a very large varicocele, which he declined to have treated, as there was not the slightest inconvenience from it. It illustrates what excursions can be taken from the normal standard of parts without especial discomfort, and also shows how hard it is to define the point where the normal ends and the pathological begins.

DEEP VARICOSE VEINS.

Seven cases have come under my care of adults between thirty and fifty years of age, who were obliged to stand in their occupations, complaining that, as the day advanced, localized and gradually extending areas on the surface of the thighs and legs became painful. In five cases, the sensation was described as that of the tearing of tissues; in the two others, as if the part had been burnt. These areas varied in size from a ten-cent piece to the size of the palm of the hand. No perceptible external varicosities, except small, dilated venules, were noticed in these cases, and the diagnosis of deep varicose veins was made from the history of the onset, and from the fact that a well-fitting bandage or elastic stocking completely relieved the symptoms.

Doubtless many of the obscure aches and pains in the lower limbs that patients complain of could be relieved by a recognition of this condition.

SCALP-WOUNDS.

The surface about the wound for, at least, two inches is shaved, and the surface rendered aseptic, the hæmorrhage checked by pressure-forceps, or simple pressure, and in no case has it been found necessary to ligate a bleeding vessel. In contused or badly lacerated scalp-wounds, it has been the custom to freely lay them open, to trim off the shreddy tissue, and to unite the resulting clean-cut edges. A continuous catgut suture (small) is used, and a small drainage-tube is always inserted into any existing pocket. Primary union has been the rule under antiseptic dressings. A jersey cap, drawn well over the head, keeps the dressings in position.

In truth, I think it may be said that of the one hundred and eighty wounds incised, lacerated, neglected, punctured, poisoned, and contused, that at least ninety per cent. of them have, after having been rendered thoroughly antiseptic, healed in a satisfactory manner under the iodoform and boracic acid gauze dressing. I believe that the primary rendering of the wound surgically clean, and the application of a dry, firm, compressing dressing, will give the most satisfactory results in wound-dressing. These dressings have been found almost invariably painless; in fact, were a wound painful, I should strongly suspect the presence

of some foreign body or decomposing clot beneath the surface.

FOREIGN BODIES IN THE HAND.

Needles, fish-bones, splinters, etc., have always been allowed to rest quietly in the tissues, unless distinct indications of their presence could be made out from physical examination of the part, and the experience which I have had has never led me to regret the treatment of cases on this basis.

LYMPHANGITIS.

Nine cases have been treated by the use of pads applied in the manner advocated by the late Mr. Gamgee, with very satisfactory results. Within twenty-four hours the redness has begun to fade, and in forty-eight hours, wrinkling of the skin, showing a subsidence of the swelling, has occurred.

In addition to the use of these pads in the treatment of lymphangitis, I have used a ten per cent. solution of resorcin in lanolin, with results that were quite satisfactory. It is, of course, very difficult to decide as to the efficiency of two remedial measures, when used together in the same case. Enlarged glands in the groin, axilla, and neck have apparently decreased in size under the use of lanolin and resorcin.

FRACTURES.

Naturally in an out-patient service the fractures are principally of the upper extremity. One hundred and fifteen have occurred, and I shall only speak of a few classes of cases.

All splints have been carefully covered with sheet wadding, protected by a carefully adjusted piece of compress cloth which retains the wadding in position throughout the treatment of the fracture, and second coverings of splints have rarely been necessary. The covering of the splint with cloth would seem from my experience to be more comfortable for the patient and more economical, in — that in gross — less materials are used in the continuous treatment of the fracture.

FRACTURES OF THE NOSE.

Four cases have been treated in a satisfactory manner by rectifying the deformity by manipulating and fixing the fragments in position by means of a tin splint devised by Dr. Post.

FRACTURES OF THE CLAVICLE.

Twelve cases have been treated by various methods. By the application of the "many-tail" bandage, "the Sayre," or "the Kelly" bandage. Velpeau's bandage has been rarely used, owing to its instability; this, however, may be easily overcome by stitching the bandage in position and coating it over with silicate of potash, starch or dextrine. The amount of deformity in many cases had been considerable from callus formation, but this has melted away as time passed, in a surprising fashion.

RETENTION BANDAGES AS APPLIED TO THE SHOULDER.

One of the most useful bandages is one devised by Mr. C. M. Whitney; it securely holds the arm at the side, with a minimum amount of material.

The many-tail bandage has been largely used, but is open to the objection that it frequently cramps the arm and hand so that the patient has not infrequently complained more of the bandage for the first forty-eight hours than of the injury for which the bandage is applied. This, of course, is true of all retention bandages in which the arm is flexed upon the chest, but has been especially marked in the "many-tail" bandage.

FRACTURES ABOUT AND INTO THE ELBOW-JOINT.

Six have occurred. Two of the olecranon, one of the internal epicondyle, one of the internal condyle, and two fractures into the joint.

One of the fractures of the olecranon illustrated the importance of carefully examining injuries over the point of the elbow associated with great swelling. On the first day the patient was supposed to have simply a severe contusion over the olecranon, but on the second day the djagnosis was made clear by a distinct sulcus appearing between the fragments of the bone. Both cases were treated in the following manner: A roller bandage was applied from the finger-tips, up the arm to the seat of fracture. A well-padded straight splint was then secured to the palmar surface of the arm. Then a small roller of compress cloth was placed against the superior fragment of the olecranon, the ends of this roller being tied down firmly, in an oblique direction, downwards and forwards, to bring the triceps fragment in contact with the ulna fragment of the olecranon.

This certainly brought the fragments into apposition, but both of the cases were narrowly watched, and the bandages were daily readjusted. I am sure that carelessness in the adjustment of this device might lead to gangrene or local sloughs. The splints were removed at the end of two weeks and gentle passive motion encouraged. The results have been fairly satisfactory in that the arms can be flexed to at least a right angle, but supination is somewhat limited.

The T fractures were let free from the splints on the fourteenth day, but passive motion was not made until the expiration of twenty-one days.

It is too early in these cases to speak of the results. Early passive motion is still a mooted question in this class of cases, but an expression of opinion regarding its advisability by the gentlemen present might be a matter of interest.

FRACTURES OF THE METACARPUS.

Fifteen cases have occurred, and I regret to say that the results have not been satisfactory. Thirteen have been caused by blows with a clenched fist. Some have been placed upon straight palmar splints with pads suitably adjusted to correct the deformity; others have been treated by the hand being flexed over a suitable sized roller bandage, but in only two cases has the treatment been concluded without a certain amount of dorsal angularity; this deformity, although quite marked in a few cases has not impaired the usefulness of the hand. I shall hope to in the future use dorsal splints and extension. In one case extension was secured by means of a splint, which served to correct a marked deformity in a fracture of the first metacarpal bone, in a child.

It was simply a tin palmar splint with the projection for the thumb extending well out beyond the end of this member, to secure a fixed point to extend towards. In addition there was a spur or leaf of tin, which was so adjusted that it would fold over from

the radial edge of the splint on to the deformity and retains it in its corrected position.

COLLES' FRACTURE.

There have been forty-five cases of Colles' fracture, and from these I have been taught a few facts.

At least one-half of the patients supposed that they had simple sprains of the wrist, which opinion had been confirmed in many cases by friends and physicians that they had consulted. At the risk of being tedious I will give a few details, which I have been led to adopt in the treatment of this injury.

Both arms of the patient have been usually bared to the elbow, that an accurate comparison might be made of the wrists, forearms and hands. In my notes I find that 62 per cent. of the cases had the characteristic silver-fork deformity; 92 per cent. had localized tenderness at the seat of fracture in the radius, and by this is meant the point of extreme tenderness, for frequently the whole wrist and arm were tender.

The general contour of the arm having been observed, the bony land-marks located and their relative position determined, especially the relative planes of the tips of the styloid processes.

The fracture has been reduced by manipulation. Various methods have been tried, but the grip figured below has been found to give the operator the most complete control of the fracture.

Gentle traction is first made, and then the hand is successively extended, abducted and strongly flexed. During abduction the impaction, (if it exists), will be felt to give away, and on the completion of flexion the deformity will usually be found to have been completely reduced.

I have rarely been obliged to repeat this manipulation, but I never consider the fracture "set," until the deformity is completely reduced and will remain so without traction or pressure. This latter point is, I believe, a very important measure, for I cannot help thinking that it makes but little difference what kind of splint is used so long as the fracture is primarily completely reduced.

I have used all kinds of splints, but for my own part I prefer the palmar splint of Dr. Bolles, with a piece of mill-board accurately moulded to the dorsum of the fore-arm and hand.

These splints are secured by lightly applied broad adhesive plaster straps; the principal retention being secured by a snugly applied roller bandage. The pain for the first twenty-four hours is considerable,—an analysis of the cases shows that it has persisted from three to five days; usually the readjustment of the bandage at the end of twenty-four hours has relieved the greater part of the pain.

Tenderness has persisted at varying time in these cases, but has averaged seventeen days.

The dorsal splint has been omitted in about three weeks and the palmar at the expiration of four weeks; in a few cases the splints have been retained five or six weeks, and in one case, owing to delayed union, eight weeks. The arm has been removed from the sling in many cases, before the splint has been omitted; this I have been led to do from an apparent relapse of the deformity where the arm without splints was kept in a sling that adducted the hand on the fore-arm.

This recurrence of deformity from the too early removal of splints, would seem to be a matter of some importance, and certainly no "hard and fast rule" can be made, assigning a definite time for the removal of splints. Other things being equal, the older the patient the longer the fracture should be protected, and further, one might say that the older the patient the earlier passive motion should be begun; so that between these indications we must shape our course. In a few cases I have applied straight dorsal and palmar splints, these splints being shortened as soon as practicable, that the fingers might be set free.

Although careful records have been kept of these cases, I cannot speak statistically regarding the return of the hand to usefulness, but only from my impressions. When the hand is released from the splints there is rarely any ability to flex or extend the wrist joint, and it is only after patient and frequently painful efforts that complete restoration of mobility is obtained, and that in two, three or more months.

Perhaps one of the commonest and most troublesome causes of disability that has occurred, has been the persistence of the effusion that takes place into and about the sheaths of the flexor tendons forming a distinct elastic pad over the palmar surface of the wrist. These cases have been greatly benefited by massage, and it would seem that this measure should hold an important place in the convalescent treatment of fractures.

The most troublesome class of Colles' that have been met with are those occurring in women past the middle period of life, of a rheumatic diathesis; in these cases the early release of the fingers is a very important procedure, and the administration of the iodide of potassium and wine of colchicum has apparently been of benefit.

The subject of the treatment of fractures has been of great interest to me, and I am convinced that we do not always elicit all the information from the examination of a fracture that is obtainable, and which may be of importance.

Unless the patient is under the influence of an anæsthetic, the examination is necessarily painful, and I have made it a rule which I have rarely broken, to always explain to the patient that it is necessary to inflict a certain amount of pain; the maximum pain should be reserved until the last, for if inflicted at the start a barrier is erected by the patient which may prevent the examiner from eliciting important information regarding the details of the fracture.

— Dr. von Nussbaum, of Munich, has recently performed his five-hundredth ovariotomy. The occasion was celebrated by his students with a banquet to the distinguished surgeon.

THE MORBID CHANGES AND SURGERY OF THE NAIL.[1]

BY J. LESLIE FOLEY, M.D., L.R.C.P., OF LONDON.

Mr. President and Gentlemen: I read this paper more for my own instruction than for yours, hoping that it may provoke discussion, and that I may thereby learn the views of members of riper experience and maturer judgment than my own. The nail seems a somewhat trivial and ordinary subject to occupy the minds of learned members of this Society, but it is only by contemplating the smaller objects that we are fully able to appreciate the larger; and in practice, as in life, the careful attention to little things often tends greatly to one's success. In order properly to understand the morbid changes of the nail, it is necessary to be familiar with its normal structure. Pardon me, therefore, if I refresh your memories by briefly referring to its anatomy. A nail is a peculiar arrangement of epidermal cells: the undermost of which are rounded or elongated; the superficial are flattened, and of a more hairy consistence. That modified portion of the corium by which the nail is secreted forms the matrix, and extends beneath its root and body. The back edge of the nail or root is received into a shallow, crescentic groove in the matrix. The front part is free, and projects beyond the extremity of the digit. The intermediate portion of the nail rests, by its broad under surface, on the front part of the matrix, which here forms its bed. The part between the root and free extremity of the nail makes up its body. The matrix beneath the body is not uniformly smooth on the surface, but is raised in the form of longitudinal and nearly parallel ridges, on which are moulded the epidermal cells of which the nail is made up. The growth of the nail is effected by a constant production of cells from beneath and behind.

Excessive growth of nail substance occurs either by multiplication of the nails or increase in bulk. This anomaly includes the occurrence of nails in unusual places, such as on scapular region, on last phalanx of supernumerary fingers or toes, double nails on fingers or toes, etc.

Both go by the name of onychauxis or hypertrophy. These vary. In the first it appears spherically curved, glossy on surface; a grayish-white color, unshapely, thick, opaque, has a massive feel, and is very hard. When the whole nail is affected, its free border has a tendency to curve downwards. It may occur in various directions, according as it is disturbed in the vertical or transverse way (onychogryphosis). In its simplest form, it becomes clam-like. In other cases, it may curve spirally.

Symptoms. Loses its elasticity; becomes thickened. Loss of tactile sense. It is very much diminished, and reduced to a minimum. Patient unable to execute fine work, and, when enlargement considerable, incapacitated for work. When toe-nails affected, walking interfered with; and, at the same time, most unpleasant effects (inflammation and suppuration) are produced by nails enlarged laterally. If uncared for, they penetrate toward the lateral groove and grow in. In the second form they are slightly lustrous, dirty, yellowish-brown, or yellowish grayish-white. Externally, have well-marked longitudinal ribs; at intervals, transverse, more or less elevated ridges, and here and there, horny plates.

[1] Read before the Surgical Section of the Suffolk District Medical Society, April 6, 1887.

Etiology. Onychauxis may be congenital or acquired. In the former case, it dates from the embryoral period, and the anomaly appears in the course of life; in the great majority of cases, acquired.

Defective or altogether neglected care of nail may cause it. Uncleanliness, accumulation of all sorts of substances on the nail-bed act as irritants. This sometimes occurs in old people and bed-ridden patients.

Traumatic influences. Any considerable pressure for some time from in front or sideways on the extremities, as too short or narrow shoe, increases nutrition of nail-bed by augmented afflux of blood, and gives rise to hypertrophy.

Extension of morbid inflammatory processes of the corium and the connective tissue of the cutis to the matrix of the nail, as psoriasis, eczema, etc.

Defective formation of the nail, atrophy, etc., absence of the nails (anonychia), or their retarded growth, may also be congenital or acquired — causes much the same as in hypertrophy. Thermic and chemical irritations, traumatic influences, knock, blow, or pinch, inflammations associated with suppurative and ulcerative processes, febrile diseases, and all chronic wasting diseases, may be ranked as etiological factors. The cutaneous and nervous affections causing hyperplasia may also give rise to aplasia.

Characteristics of an imperfectly developed nail. Lustritous, delicate, a whitish-gray color, giving the impression of a thickened membrane, possessing but a slight hardness, readily broken and flexible. Dr. Ashurst observes, in a foot-note in his "Principles and Practice of Surgery," that Guenthre, a Danish surgeon, and Nillien, of Illinois, have noticed that the growth of nail is retarded during the early stages of fractures, to be resumed as repair goes on. They suggest this as a means of testing the progress of the cure, without disturbing the dressings in cases of delayed union or false joint. The growth of nail, however, may be checked by any cause which interferes with the nutrition of the part. Hence the test might not be universally applicable. Mitchell has noticed an arrest of growth in cases of cerebral paralysis. Gay the same, as a result of compression of the subclavian artery.

Nails may be deformed, degenerated, or discolored. They may be abnormally long or short, broad or narrow, flat or curved. A cut of a pen-knife will cause a bending of the nail. These deformities are not generally amenable to treatment. Too much stress is laid in works on clinical medicine as to the value of the color of the nail in various diseases. These are due to processes of nail-formation.

Animal and vegetable parasites affect the nail. The sarcoptes scabiei attacks the nail. In tropical regions, there are a number of flies which lay their eggs under the nails. Sand-fleas will cause, first, violent pain, and subsequently, paronychia, associated with loss of nail.

Vegetable parasite, onychomycosis. In only two mycoses of the skin, favus and herpes tonsurans, has it been clearly demonstrated that transferrence of their fungi will cause changes in the nail, that is, onchomycosis. Tinea favosa is rarer than tricophyton or tonsurans. The clinical features are similar. Nails brittle, frayed out, intersected, are lifted up according to the quantity of epidermis under them, become gryphotic, thickened, flake off, faded, dirty yellow color, and often become greatly disfiguring. Both the achorion schonleinii and tricophyton tonsurans produce the

above alterations. In a few cases, the nail presents a yellow-sulphur color, due to favus.

Horny growths sometimes spring from beneath the nail.

Ungual exostosis frequently appears. Both require excision.

The nail is closely related to the hair. I might mention, in passing, an instance known to me, which will serve to bear out this remark. A gentleman was camping out, some summers ago, in the Hudson Bay region. One night, a dreadful lightning-storm took place. The following morning, not only every hair on his body fell out, but he was also bereft of every nail, and remains hairless and nailless to this day, notwithstanding the use of the whole armamentarium of the pharmacopœia. The matrix of the nail is sometimes the seat of inflammation, etc. In its simpler form, we have onychia simplex; in the more severe, onychia maligna. This last occurs almost entirely in children under ten years. It is not very frequent. In Holmes's "System of Surgery," Mr. Thomas Smith states that out of seven thousand surgical outpatients of children under ten, he found the disease in nine instances only, and these cases occurred between the ages of one and seven years. May commence from a pinch or crust of finger-end, or result from explosion of fire-crackers. The swollen, bulbous-looking finger-end, the fluid effused beneath the nail; the thickened, flattened, or curled-up, unnatural-looking nail; the foul and painful ulcer exposed beneath it, with its peculiar, characteristic fœtor, and the hardened, shiny, and livid-red integument around it, are, no doubt, familiar to you all. The disease may go on until the joint is lost, or the phalanx necrosed.

I take a paronychia to be an acute inflammation of tissues underlying the nail. The ancients define a paronychia as an inflammatory tumor near the nail, involving its pulp or matrix. But in most modern works on surgery you will find described under the head paronychia, whitlow, felons, and even inflammation extending up to the hand or arm. The middle or side of the subungual tissues may be affected. Puncture, concussion, contusion, laceration, etc., may give rise to a paronychia. If the nail enlarges in width, it will press on the lateral furrow, and this, coupled with compression from a shoe, will cause a paronychia lateralis. At first, there will be great irritability of the parts, later, inflammation, suppuration, great proliferation of granulations, destruction of the cutis, of the tendon, opening of the phalangeal joint, caries and necrosis of bones. Usually the internal angle of the great toe is affected, rarely the outside of the little toe, seldom any other toe. It may assume a mild form or become chronic, with now and then an exacerbatory character, may be covered with irregular, spongy, easily-bleeding granulations. It may last for years.

Ingrowing toe-nail almost invariably occurs on the outer side of the nail of the great toe. Psoriasis may effect the nail. It may be, although not necessarily so, an evidence of syphilis. Central part of nail diseased; scabrous thickened, rough, convex, splits, deep fissure between the skin and finger. Nail resembles the concave shell of an oyster. Affection chronic and difficult to cure.

Syphilis may attack the nail. Jonathan Hutchinson[2] was one of the first to draw attention, not only to the state of the nail in syphilitic psoriasis but in congenital syphilis. Nails, symmetrically affected, dry, brittle, fissured and broken at their edges, superficial layers alone diseased. There is, however, a more remarkable affection in the form of a chronic general onychitis. The nails decay and fall off; they first become opaque and much thickened, their substance is soft. The disease is due to inflammation of the matrix which is swollen and readily bleeds. Syphilitic onychia usually attacks the toe-nails and is often associated with ulcerative fissures between the toes. The inflammation is not so severe as in the non-syphilitic form. Perionyxis is a syphilitic inflammation surrounding the nail, exists in a dry and moist form. It also has a simple and ulcerative variety. Deep ulcerations forming in the latter. Mucus patches are sometimes seen under the free border of the nail.

The surgery of the nail resolves itself into operative and general treatment. If it be troublesome on account of its longitudinal growth, this must be removed with the scissors in simple cases; when the thickness is increased at the same time, use cutting pliers or saw. Paronchia lateralis in its early stage may be treated by removing that part of the nail which threatens to grow in, besides putting into the groove fine threads of charpie and ordering wide shoes. When the inflammation is extensive it is well to use the method of complicated pressure, as devised by Kaposi of Vienna. This consists in first removing that portion of the nail projecting into the inflamed surface, then the swollen edge of skin is carefully pressed downward and the widened space thus gained at the furrow, is filled with accurately inserted threads of charpie cotton. In doing this, care should be taken that the sharp edge of the nail does not come in contact with the irritated part of the skin. This done, strips of adhesive plaster(emplas diachylon) are wound round the ungual phalanx, commencing at the affected part from above downwards, each turn being moderately stretched, so as to remove the border of the skin as much as possible from the edge of the nail, to crowd it downwards. If this is done skilfully, it will cause no pain to the patient, and eases his condition at once. He can not only walk, but wear his shoes. After twelve or twenty-four hours, the dressing is taken off, foot bathed and bandaged anew. Kaposi claims that this will cure the patient in from two to four weeks. Some add medicated solution to the charpie, carbolic acid, etc. If greatly developed fungous granulations are present, they should be cut with the scissors down to the base and the bleeding points touched with nitrate of silver. In rare cases will be obliged to resort to Dupuytren's radical operation, that is, inserting pointed end of scissors beneath the nail, divide it into two parts, firmly seizing the diseased side of the nail with pliers, and pulling it out. The nail usually reappears. A great object in in-growing toe-nail is to give the feet all necessary room. In the early stage, when there is no considerable mass of overhanging integument or fungous granulations, pressure of the nail on the soft parts may be relieved by packing into the groove on the affected side, oiled cotton wool with the flat end of a probe or penknife. This may be done without pain. The quantity of wool may be increased at each application, until the soft parts are raised and pushed aside. The free edge of the nail is exposed, beneath which wool should be inserted until the natural state is restored. Nails

[2] British Medical Journal, 1865, p. 48.

should be allowed to grow so as to form a right angle at the outer corner. If much inflammation, the toe may be kept in water dressing during treatment. Overlapping integument kept in natural relation to the nail by strips of adhesive plaster. Dr. Tilbury Fox says, "In-growing toe-nail is easily cured by softening it and then scraping off as much as possible, so as to thin it in the middle." A similar plan may be adopted to remove splinters imbedded in the nail. Nail scraped thin over the splinter and then cut through. It can in this way be painlessly removed. When the nail cuts deeply into the flesh, causing ulceration and fungous granulations, remove it at once, using ether spray or cocaine. Dupuytren's method, as described above, is the one usually employed by surgeons. Nails may be cut by knife instead of dividing by scissors. Some surgeons prefer to remove the whole nail.

Dr. Monks has kindly called my attention to Dr. Cotting's, of Boston, method of treating in-growing toe-nail. Anything emanating from Boston is sure to bear the impress of sterling worth. It seems to me to be the most feasible of all methods. He removes the fleshy part of the toe at the side of the nail so that it will have nothing in which to imbed itself. It is no doubt well known to you all. In treating onychia, remove the nail by evulsion, then dress the ulcerative surface with Black wash, or the old standby, Abernethy's solution, iiʒ liq. potass. arsenitis ad aq. iʒ. Arsenic has a beneficial effect on onychia. Dr. Moreloose, of Ghent, was the first to recommend the powdered nitrate of lead in onychia maligna. It has afterwards been used with great success by Prof. Vauzetti, of Padua, and Sir William MacCormac, of London. It causes considerable pain when applied, but its results are excellent. In severe cases a great portion of the disease with nail may be sliced off. In syphilitic onychia Black wash is the remedy "par excellence." Amputation has occasionally been performed for the cure of onychia maligna. Tonics should always be given. Dr. Livinq recommends very highly the giving of arsenic in non-syphilitic psoriasis; a tonic will add to the effect. In the syphilitic, mercury is of course the remedy. Appearance of nail improved by filing down with sand-paper. Skin near the margin dressed with white precipitate ointment. We must trace and treat the etiological factors. If an eczema exists this must be treated on dermatological principles, diachylon ointment, etc. In stubborn cases, Prof. Geben recommended using vulcanized rubber stockings and gloves. With all these diseases associated with connective tissue and papillary hypertrophy at the terminal phalanges, pachyderma, ichthyosis, verucca, etc., little can be done except keeping the affected part clean, and removing injurious influences. When syphilis attacks the matrix, anti-syphilitics required; when animal and vegetable parasites are present, anti-parasitics indicated. Ulcerative perionyxis is one of the bugbears of surgical therapeutics. Iodoform and nitrate of silver might be tried. In defective nail-formation, endeavor to find out the causes and treat them. Build up the system with tonics. Pressure by means of the wax nail is useful here. In all cases we should see that the shoe is not at fault, that it fits well, not too loose nor too tight. If the patient is a baker, carpenter, etc., and liable to irritation of the fingers, it is well to surround the end of the phalanx with soft wax.

RECENT PROGRESS IN DISEASES OF THE NERVOUS SYSTEM.

BY PHILIP COOMBS KNAPP, M.D.

ARSENICAL PARALYSIS.

Dana[1] reports two cases of pseudo-tabes from arsenic: one, where the arsenic was given in large doses medicinally; the other, where a single large dose was taken with suicidal intent. Both patients had burning feelings and formication, and sharp pains in the legs. There was pronounced ataxia and loss of muscular sense. In one case there was some cutaneous anæsthesia; in the other, cutaneous sensibility was normal, but there was hyperalgesia. There was some muscular weakness, and static and locomotor ataxia. In one case there was optic neuritis, and in the other the fundus was normal. The cutaneous reflexes were normal, the patellar reflex absent or greatly diminished, and there was a partial reaction of degeneration.

The writer compares these cases with the pseudo-tabes of alcoholic subjects, and the pseudo-tabes that follows diphtheria, and thinks it very probable that the lesion in arsenical pseudo-tabes is also a multiple neuritis, and not a diffuse myelitis, as has been held by Seguin and others. The lesion in post-diphtheritic and alcoholic paralysis is known to be a neuritis, and arsenical paralysis resembles the other forms so closely as to render it probable that it, also, is due to a similar lesion. The writer gives a very full bibliography of the subject, and draws the following conclusions:

(1) A disease resembling tabes dorsalis may be caused by arsenic, either given medicinally, absorbed from wall-paper, or given in a single dose.

(2) Arsenical paralyses of this type, and arsenical paralyses of other types, are not due, at least as a rule — to a diffuse myelitis, as has been taught, but to a multiple neuritis.

(3) Arsenical paralyses, like those from diphtheria, alcohol, lead, and probably other infections and poisons, are of two types:

a. The ordinary mixed motor and sensory paralysis, the motor troubles and atrophy being more marked.

b. The pseudo-tabetic form, in which there is no pronounced motor paralysis, but marked sensory troubles, and especially ataxia.

EXOPHTHALMIC GOITRE.

In a case of exophthalmic goitre recently reported by Jendrássik,[2] beside the cardinal symptoms of exophthalmos, goitre, and tachycardia, together with tremor and restlessness, there were also noted paralysis of the ocular muscles, of the facial and masticatory muscles, and, to a lesser degree, of the muscles of the pharynx and of the upper extremity. The writer satisfied himself that this paralysis was nuclear, and not peripheral — an external ophthalmoplegia, due to disease of the nuclei in the medulla, a polioencephalitis superior (Wernicke), or, as he prefers to call it, poliomyelencephalitis superior. He questions whether the presence of the symptoms of exophthalmic goitre and of ophthalmoplegia are due to a mere coincidence. He cites other cases like the one reported, and suggests that exophthalmic goitre may be due to disease of the medulla or mesencephalon. Since three distinct and

[1] Brain, January, 1887.
[2] Arch. f. Psychiatrie, xvii, 301, 1886.

distant parts of the body are involved, the lesion must be located in some place where the different efferent nerves lie near one another. He contests the theories that exophthalmic goitre is a general neurosis, or a lesion of the cervical sympathetic, and claims that it is due to a central lesion, located in the medulla or mesencephalon. The fact that only one or two of the three cardinal symptoms may be present is explained by supposing that only one or two nuclei are involved. Various cases of exophthalmic goitre show, moreover, that there are not infrequently symptoms present which point to a bulbar lesion — ophthalmoplegia, diabetes mellitus, etc. — and, in other cases, the existence of muscular atrophy shows that the nuclei in the cord are also affected. The writer, therefore, believes that in this disease there is a constant and circumscribed lesion of the gray matter in the medulla, about at the level of the nucleus of the facial. This theory is further corroborated by the experiments of Filehne, who found that injury of the anterior fourth of the restiform body was followed by the three cardinal symptoms of exophthalmic goitre.

TABES AND SYPHILIS.

Strümpell has recently published[3] a valuable study of the relation between syphilis and tabes and paretic dementia. The very large percentage of syphilis in patients with tabes has long been recognized, although the relation between the two diseases has not been determined. Tabes is not, however, a true tertiary manifestation of syphilis, for the anatomical process is unlike the syphilitic gumma, there being no new growth of cells, but only a degenerative atrophy. Tabes, moreover, is not amenable to anti syphilitic treatment. The connection is not direct. In other infectious diseases, however, we see a similar phenomenon — nervous after-symptoms, undoubtedly connected with the previous disease, as, for instance, the simple degeneration of nerves after diphtheria, which has nothing to do, anatomically, with the croupous-diphtheritic disease of the mucous membrane. This does not depend upon the organized agents of diphtheria; the bacilli do not attack the nerve, but a chemical poison is formed, of which we know nothing. The same holds true of typhoid, dysentery, etc. Tabes is also a nervous after-disease. The lesion is distinct from syphilis, and is not due to the action of the syphilitic cocci. The period of time between syphilis and tabes, however, is very variable, and tabes never recovers, as diphtheritic paralysis does. Syphilis, however, unlike diphtheria, is a chronic, infectious disease, which has a long latent period; the tertiary manifestations appear five or ten years after health has apparently been restored, and so the chemical agents may long lie hidden. This is also true of the other chronic infectious diseases, tuberculosis and lepra, where neuritis may develop late. Tabes does not always advance; it may stand still. In its treatment, although anti-syphilitic remedies are of no more effect on the tabes than painting the fauces on diphtheritic paralysis, they do have a favorable influence in that they check the advance of the disease by counteracting the agencies which keep the poison going. The same arguments hold true for paretic dementia, which Möbius calls "tabes of the brain." The localization of the action of the poison differs, just as in pharyngeal diphtheritic paralysis and diphtheritic ataxia. All cases of tabes, however, are not due to syphilis. Different poisons may act in the same way, just as we see multiple neuritis following alcohol, tuberculosis, typhoid, or some special infectious agent.

[3] Neurolog. Centralblatt, October 1, 1886.

AMYOTROPHIC LATERAL SCLEROSIS.

Charcot and Marie have reported[4] two cases of amyotrophic lateral sclerosis in which careful autopsies were made. They were both typical cases with spastic phenomena in the lower limbs, muscular atrophy beginning with the thenar muscles, and bulbar symptoms. At the autopsy they found a total disappearance or a diminution in the number of the large pyramidal cells in the cortex, in the central convolutions and the paracentral lobule, and also a certain number of granular bodies. These granular bodies were found in the white substance throughout the pyramidal tracts, from the cortex to the anterior cornua, and their presence is thought to be an earlier and more trustworthy sign of disease than the presence of sclerosis, even as revealed by the best and latest methods of staining. The disappearance or atrophy of the motor cells of the anterior cornua in the cord was of course also confirmed. The morbid process in the pyramidal tracts in the cord was found to extend beyond the limits of the tract as defined by secondary degeneration, which was thought to be due to an extension of the inflammatory process to the adjacent fibres. A slight degree of sclerosis was also noted in the columns of Goll.

Koschewnikoff[5] reports an autopsy on a case with atrophy of the muscles of the neck, shoulder, and upper arm, increased tendon reflexes, and bulbar symptoms. He found degeneration of the peripheral nerves, atrophy of the motor cells in the anterior cornua, and many granular cells in the anterior and lateral columns. Granular cells were also found in the pyramidal tract up to the gray matter of the cortex. On hardening the cord a degeneration was noted which extended beyond the limits of the pyramidal tract into the anterior columns. The nuclei in the medulla were also degenerated. In the gray matter of the central convolutions and paracentral lobule, he noted a great diminution of the giant pyramidal cells in the inner half of the cortex, and those that remained were distorted and atrophied. The small pyramidal cells in the upper half of the cortex had suffered no changes, and the lower portion of the ascending convolutions was nearly normal.

Charcot and Marie maintain that the morbid process may begin anywhere in the motor tract, from the cortex to the anterior horns, and may affect any region, either the medulla or the cord. This is in accord with the views of Strümpell, who holds[6] that labio-glosso-laryngeal paralysis, amyotrophic lateral sclerosis, and progressive muscular atrophy are merely clinical terms for different localizations of one and the same morbid process. Gowers[7] goes a step farther in claiming that a degeneration of the pyramidal tract exists in every case of progressive muscular atrophy that he has seen, or read a report of, since Charcot's original investigations on amyotrophic lateral sclerosis. This assertion is rather too sweeping, for Strümpell cites a case of progressive muscular atrophy where the pyramidal tracts were intact.

CEREBRAL INFANTILE PARALYSIS.

Kast[8] reports two cases of this affection with autopsies which were made at an earlier stage than any yet reported — one of them being made only fourteen months after the onset of the symptoms. In both cases there was a wasting of the convolutions of the brain on the side opposite to the paralysis, and the microscope revealed a degenerative process, a disappearance or diminution in the number of the ganglion cells, especially the small pyramidal cells in the second and third layers. There was also a decided increase in the neuroglia, together with an accumulation of spider and granular cells, which extended down into the white substance. The hemisphere on the affected side showed a decided arrest of growth. The writer, on the strength of these autopsies, considers that Strümpell's hypothesis of a poliencephalitis incomplete, as there is also a leuko-encephalitis. He also failed to find the peri-vascular changes regarded by Jendrássik and Marie as the initial process, or any traces of the venous thrombosis, which Gowers has long considered to be the morbid change giving rise to these atrophic conditions of the brain.

HYSTERICAL HEMIPLEGIA.

Oserezkowski, in a recent thesis,[9] has called attention to the following diagnostic points in the distinction between hysterical and organic hemiplegia:

(1) Hysterical hemiplegia developes most frequently after some psychical irritation.

(2) It often comes on as a monoplegia, and may be distinguished from the organic form by severe disturbances of sensibility, contractures, etc.

(3) In hysterical hemiplegia the peripheral parts are less paralyzed than the central parts, and the small joints are less affected than the large.

(4) Mobility returns soonest in the peripheral and small joints. The opposite is the rule in organic hemiplegia.

(5) The face and tongue are rarely paralyzed. (Charcot says that facial paralysis may be simulated by spasm of the opposite side of the face, and Roth, in the discussion on Oserezkowski's paper, thinks there is a real hysterical facial paralysis.)

(6) Anæsthesia is parallel with the paralysis.

(7) The distribution of the anæsthesia is peculiar. In full hemianæsthesia the hand and foot may be free.

(8) Aphasia is rare, and is replaced by dumbness.

(9) Hemianopsia is very rare.

(10) The diagnosis of hysteria is based on anæsthesia of the fauces, polyopia, transfer phenomena, hysterogenous zones, etc.

MUSCULAR ATROPHY IN HYSTERIA.

Babinski has recently reported[10] a series of cases which, in his opinion, seem to show that, contrary to the current belief, trophic troubles may be present in hysteria. The cases all had paralysis, and hemianæsthesia, most pronounced in the paralyzed limb. In most of the cases there was also contracture, and in one there was loss of smell and taste on the affected side with peripheral limitation of the field of vision. In all the cases there was a simple muscular atrophy of the paralyzed limb, with a diminution of two or three centimetres in circumference. In one case a magnet produced transfer and return of sensibility. The atrophy diminished as the arm regained its power. From the anæsthesia, the variations in the amount of contracture, the transfer phenomena, and other manifestations of hysteria, the writer decides that the atrophy also was of hysterical origin, due to a functional neurosis, a purely dynamic alteration in the trophic centres.

"DIFFUSION" ELECTRODE.

Adamkiewicz has recently devised[11] a new form of electrode to be used in the treatment of neuralgias for the purpose of obtaining local anæsthesia. It was his object to aid the action of the constant current by adding some medicament whose absorption might be furthered by the kataphoric action of the current itself. For this purpose he tried chloroform, but found that with the ordinary electrode he could not keep enough chloroform constantly applied to the skin to get any anæsthesia, owing to the rapid evaporation. He, therefore, has contrived a hollow, metallic electrode, closed by a carbon plate. The hollow chamber is filled with chloroform, the electrode itself is covered with flannel as usual, and the covered carbon surface is applied to the skin. This electrode is made the anode, and a mild current, gradually increased to 5–7 ma., is passed through the patient for five minutes. The local anæsthesia thus produced is well-marked, and affords great relief, especially in trigeminal neuralgia. Paschkis and Wagner have criticised Adamkiewicz's work.[12] They claim that chloroform is an absolute non-conductor, and that a similar anæsthesia can be produced by the application of chloroform alone to the skin, that electricity adds nothing, and causes no kataphoric action whatever. Adamkiewicz, however, by subsequent experiments, has proven[13] that there is a much greater degree of anæsthesia produced by the combined application of chloroform and galvanism than by chloroform alone, while galvanism alone produces a slight increase of sensibility. There is, therefore, he claims, a true kataphoric action, and the new instrument is of value as an agent in producing local anæsthesia in neuralgia.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

JUNE 11, 1887, the President, DR. WILLIAM L. RICHARDSON, in the Chair.

DR. ROTCH gave an abstract of a paper on

THE ARTIFICIAL FEEDING OF INFANTS,

which he had read before the Society at the last preceding meeting. Further investigation, he thought, was called for in regard to this subject, for a number of reasons.

First: The great proportionate mortality of the artificially fed over the breast fed.

Second: The difficulty experienced by physicians, in certain cases, in regulating the digestion, resulting notably in a diversity of methods employed, and hence

[8] Archiv. f. Psychiatrie xviii, 427, 1887.

[12] Neurolog. Centralblatt, September 15, 1886.
[13] Neurolog. Centralblatt, November 1, 1886.

showing that no one method has been markedly successful.

Third: Infantile dyspepsia induced by errors in feeding, occurs at certain periods during the first year of life to a greater extent than in the intervening periods, and of these periods, the first, or that which is embraced in the early weeks of life, is the most important, because it is the time when the function of digestion is being established, and is in a state of unstable equilibrium, and therefore following the rule of functional establishment, the stomach is in its most active period of growth: and hence the most careful regulation of the bulk of the food given is needed to correspond to this activity, both to make the stomach digest the food in this period, and also, which is just as important, to avoid weakening the digestive function by too great taxation either in quantity or quality, and yet provide the proper materials for functional nutrition, thus avoiding by prophylaxis, the dyspepsia of the later periods of infancy and childhood, the seeds of which are continually being sewn in this early transitional period.

We, therefore, have the question not only of infantile digestion, but infantile development to deal with, and we must recognize at once that the quality of the artificial food is merely one of a number of factors which make up this problem.

Common sense and clinical experience teach us that nature must be our guide; but nature's method of feeding is a complex problem, of which the chemical analysis of human milk is only one factor, and hence it is a great mistake to simply try and copy this one factor in artificial feeding, as the other factors are equally important in making up the sum total of the problem, and we therefore can only, by endeavoring to copy the other factors also, expect to bring the mortality of artificial feeding anywhere near that of human feeding.

Although favorable results can be shown with almost every food, instances continually occurring where one food will fail and another, when substituted for it, succeed, yet these successes are merely temporary, the mortality always remaining far above that of human food. Cows milk is the universal menstruum of infant foods all over the world, and, as will presently be shown, is the actual food which the infant is getting; hence it is irrational and unfair to speak of and give the credit to the various artificial foods, when we really should speak of our general and universal menstruum, cow's milk, with its modification to a greater or less degree by certain adjuvants under the name of infant foods, which all supply about the same variety of ingredients and in common, such small amounts of these ingredients as to be of little benefit in nourishing the infant, and would not nourish it unless aided by cow's milk.

What are the factors of this problem which nature freely offers to us for investigation?

First, we find a receptacle, the human breast, which mechanically provides a fresh supply of food at proper intervals, absolutely prevents fermentation of the food before it enters the infant's mouth, forms the mouth by the process of sucking, and by the same process incites to action the necessary digestive fluids; again, by collapsing as it is gradually emptied, it avoids a vacuum, thus allowing the food to flow continuously, and practically is self-regulating as to the amount of daily food, according to age of the infant.

Second, the food itself, adapted to the infant's needs of digestion and development by its temperature 98 to 100 Fahrenheit, its alkaline reaction and its chemical constituents. Given these factors, how nearly can we approach them artificially? First, the receptacle. Human ingenuity has not yet been able to devise anything which approaches nature's receptacle, and the best that we can do to offset this perfect receptacle, complex in its mechanism, is to adopt that which is exactly the reverse; namely, a receptacle of absolute simplicity, and thus combat the tendency to fermentation through perfect cleanliness, preventing the receptacle from becoming a source of fermentation.

After various experiments with the glass blower, with a view to fulfil this end, I have had made and fitted, for convenience, to a box, what are practically enlarged test-tubes blown into a glass standard, and the interiors of which are entirely free from angles. They also are intended, by holding the proper quantity, which at certain periods should be given to the infant during the nursing period, to enunciate the importance of giving definite amounts of food in accordance with the age. This receptacle, however, has to receive a food which is non-sterilized, and hence the food itself should be sterilized in the feeding-tube before giving it to the infant. The sucking process is practically identical in both problems.

The artificial receptacle cannot collapse, but a small hole at the end of the feeding-tube, by allowing air to enter, prevents a vacuum being formed, and regulates the rapidity of the flow, while it allows it to be continuous.

The artificial receptacle is not self-regulating; hence we must first determine anatomically the amount which nature provides for the average infant at different ages, and from these average figures deduce the proper amount for the especial infant according to its age and weight.

. . . . . .

It is possible then, in artificial feeding to approach the standard human breast-milk much more nearly than is usually attempted, and there is no reason why clinical results should not be much improved if physicians will only take additional time and trouble to follow more uniformly nature's teaching. In all classes of life a much greater amount of time, expense and thought is given proportionately to the preparation of food for the adults of the family than for the infants, and this is a mistake, both from a humanitarian and an economical point of view, for the infant is much more susceptible to irregularities of diet, with their resulting suffering, than the adult, and when once the train of symptoms, usually called dyspeptic, is established, infinitely more trouble and expense is entailed, than if more exact methods of feeding were adopted before the digestion has been tampered with.

In the early weeks of lactation, after the mammary function has been fully established, it is well to have a number of analyses made of the mother's milk, and to keep the results as a control record to act as a guide for the preparation of an artificial food in case, as so frequently happens, something should occur to end the nursing at an early period, for it is highly probable that the digestive function of the individual infant may have certain idiosyncrasies which correspond to some idiosyncrasy in the percentages of its mother's milk, and in cases of difficult digestion where

the artificial food, which has been made to correspond to the analysis of average woman's milk, fails to agree, reference to this control-record may accomplish the solution of the problem sooner than if we had to ascertain experimentally by changing in turn the percentages of the different ingredients, in which ingredient the idiosyncrasy of this especial infant was to be found. The assistance of the skilled chemist is too little sought after in determining these questions of infantile digestion and nutrition, and in the future must necessarily be made use of, if there is to be any advance for the better in this subject of artificial feeding.

I have devised a simple apparatus for sterilization of artificial food among poor people; however, the sterilization can easily be accomplished by placing the nursing bottle containing the artificial food, and with a rubber cot fitted tightly over the neck of the bottle, in a covered colander on the tea-kettle. Sufficient sterilization is accomplished by the steam in from fifteen to twenty minutes, a longer time not being advisable, as, so far as my investigations have gone, certain chemical changes noticeable to the eye, take place, when the sterilization is prolonged beyond this time, while in twenty minutes, the food so far as can be ascertained by taste, sight and odor, is identical with the same mixture before it is exposed to the steam.

In the process of steaming in this way, ebullition does not take place, and chemical changes apparently do not occur in the food: this will, in all probability, in the future make sterilization of the food by steam preferable to that by boiling, especially as the former method is, if anything, rather more simple in its details than the latter, where the food is to be prepared from several ingredients, and simple cow's milk, which, as already explained, is not a proper food for young infants, does not represent the artificial food to be sterilized. Sterilization by steam has practically already been adopted in one of the Boston Dispensary districts, among a number of poor people, and in no instance which has been brought to my notice, have the mothers failed to understand the details or objected to it as being more troublesome than boiling.

Many interesting and instructive cases could be cited and must occur in the practice of every physician, illustrating the importance of not omitting the careful regulation of every factor of the problem, when we attempt to substitute an artificial food for the natural method of feeding, and proving that no one factor can be given undue prominence at the expense of the others, without in some way causing disturbance to the digestion and general nutrition. Making the food alkaline will at times rectify an otherwise intractable digestion; again, sterilization is the only change that is needed.

I have a number of cases showing the importance of a precise regulation of the fat percentage, and also of the sugar and the casein, while the food, although chemically correct, has often proved a failure because it was given in improper quantities or at irregular intervals.

Where an infant, then, is to be fed with artificial food, give precise directions as to the times of feeding, the amount at each feeding, and the apparatus which is to be used. See that the analysis of the food corresponds as closely as possible to that of human milk; give instructions as to the proper temperature of the food; see that the reaction is alkaline, and then if there is any difficulty with the digestion, sterilize the food. If this is not successful, refer to the control-record and adapt the food to any maternal idiosyncrasy shown by this record. If no control-record has been kept, experimentally try to discover the especial idiosyncrasy of the individual infant by changing the percentage of the fat, sugar, casein, or ash.

Dr. Abbot said that while he believed it was best for the stomach to do its own work when it was able, he had had very good results from peptonizing the milk when infants were unable to digest it without artificial assistance. He had found, however, that the peptogenic powder would do its work just as well in the stomach as when added to the milk some time before it was administered. His present method, therefore, was to add the powder to the warmed milk just before using it, and in this way no bad taste was developed in the milk, which to some infants is so objectionable. He believed it was unnecessary to use bicarbonate of soda where the peptogenic powder is employed; in fact, the milk was sometimes made thereby too alkaline, and in one case, to which he alluded, in which the prepared milk disagreed with the infant, the excessive alkalinity was obvious in the fæcal discharges. He believed the amount of lime-water usually added made the milk sufficiently alkaline.

Dr. J. Stedman said that it was very difficult to get good cow's milk; most of it was deficient in fat. He had found a considerable degree of idiosyncrasy in infants in regard to their food: sometimes twins will not do well on the same milk. He had lately used Robinson's barley with success; but the barley should be boiled for thirty minutes. He believed that the sterilization was very important, and inquired what was the effect on milk of boiling.

Dr. C. W. Townsend, present by invitation, said: Sterilization of milk by the process suggested by Dr. Rotch is most exact and scientific, but in that class of people where it is most needed even the more simple method spoken of by Dr. Rotch might be beyond their power to carry out properly. Boiling is, of course, the simplest method of sterilization, and one which the poorest and most stupid could carry out, but the question naturally arises as to what effect this process has on the character of the milk. Boiling kills not only the disease germs and putrefactive bacteria, but, according to Newton and Wallace,[1] changes and drives off tyrotoxicon, one of the poisonous ptomaines produced by these bacteria. This takes place at a temperature of 180° F.

What are the chemical changes that take place in the process of boiling milk? The odor and taste are decidedly changed, and this to some adults and older children may make boiled milk unpleasant, but infants, in my experience, rarely object to it. This peculiar taste is due, according to Schreiner,[2] to the sulphuretted hydrogen which is evolved; there is also a diminution in the gaseous constituents of the fluid, and a change in the amount of ozone present. As the boiled milk cools in contact with the air, a scum forms, which is the albumen coagulable by heat entangling in its meshes a certain amount of fat. This coagulable albumen, according to Winter-Blythe, equals one-fifth of the casein in amount.

As to the effect of boiling on the digestibility of

[1] Philadelphia Medical News, September 25, 1886.
[2] Chem. Centralbl., iii, Folge ix.

milk there is a difference of opinion. A general idea is that boiled milk is more constipating than raw milk, but the accuracy of this statement is open to doubt. According to Skreiner and to Randolph,[3] boiled milk is more quickly coagulated by acids than raw milk, while the reverse is the case with regard to the action of rennet. Randolph found that raw milk was more readily digested artificially than boiled milk. He came to the same conclusion by experiments on natural digestion. This he did by syphoning out the contents of the stomach of healthy men at various intervals after the ingestion of weighed amounts of raw or boiled milk. Reichman,[4] however, in a series of similar experiments on living subjects, arrived at a directly opposite conclusion; namely, that boiled milk was more easily digested than raw, and that this difference was due to the fact that in the stomach boiled milk forms smaller and softer curds than does raw milk. Dujardin-Beaumetz [5] disagrees with both of the above investigators, in that he finds no difference between raw and boiled milk from the point of view of digestibility. He refers to Pinard, however, as saying that prolonged boiling peptonizes a part of the albuminoid substances contained in milk.

DR. BUCKINGHAM, present by invitation, said that he had supposed that boiled milk was partly predigested by fire; and that there was to this extent the same objection to its habitual use that Dr. Rotch had urged against the use of predigested foods in general. For this reason, as well as on account of its taste, he had never made use of it.

The case referred to by Dr. Abbot is an example of the bad effect of making the milk too alkaline, which is as great a departure from the normal percentage as is making it too slightly so. He had himself had the same experience. It is, however, well recognized that the human milk is more alkaline than cow's milk, a fact which he had verified for his own satisfaction the preceding summer, by testing with litmus the milk of every woman who brought a nursing child to the Children's Hospital Medical Clinic, during a period of several weeks. With the exception of three women whose children were very sick, the milk was uniformly strongly alkaline. Cow's milk, as we get it in the city, is not uncommonly neutral, or but slightly alkaline, sometimes acid.

The speaker continued, that the paper of the evening had been of great use to him personally, by its demonstration of the reason for the undeniable success of some of the patent foods, foods of which the construction appears at a superficial glance to be entirely irrational. The correctness of the reader's position that the child is not fed with this, that, or the other so-called food; but with milk more or less modified by the addition made to it, is shown conclusively by the reasoning of the paper. It is also shown by clinical experience in cases where, mislead by names, a so-called food has been given to the child without milk. He had, himself, seen a bad case of rickets, apparently caused by the continued use of Mellen's Food, with little milk, in a patient whose surroundings were good, and cases of starvation from the similar use of that of Ridge's Food, appear every now and then at the children's clinics. These cases generally improve on the addition of milk.

Another point of great interest in the paper, is the sterilization of milk. We are hardly in a position to say that milk should always be sterilized, as it is probable that most babies can eat a considerable number of bacteria, at least of certain kinds of bacteria, without appreciable harm; but, on the other hand, within the past two years a number of papers have appeared, whose authors believe that they have succeeded in checking the diarrhœa of babies by the use of disinfectants. If these observations are correct, as it is likely that they are, sterilization by heat seems preferable to the use of drugs.

The Russian statistics, quoted by Dr. Rotch, are certainly very striking, and equally so whether we consider that the child adapts itself to the breast, or the breast to the child. It is not unreasonable to hope that their study has increased our power of treating the indigestion, and promoting the development of artificially-fed infants. If this be so, then the tubes shown this evening must prove convenient by their graded sizes, as well as by their form, which enables them to be easily cleaned.

DR. ROTCH, in conclusion, remarked that the mortality of the artificially fed is so much greater than that of breast-fed infants, that we cannot be too exact in our preparation of artificial foods, and that even if cow's milk alone was a fit food for the infant, which he had endeavored to show in his paper, was not the case, he should deem it unwise to interfere with the percentage of the ingredients for the purpose of sterilication as is done in boiling, for sterilization is only one of the factors of the general problem, and no one factor must assume undue prominence at the expense of the others, as he had already stated. Moreover, where a mixture of several ingredients is made to correspond to the analysis of human milk, we destroy the intention of this analysis by either steaming too long or by boiling, and we do not ever know to what extent we have tampered with the analysis, so many chemical changes at once arise.

SUFFOLK DISTRICT MEDICAL SOCIETY.
SURGICAL SECTION.

G. H. MONKS, M.D., SECRETARY.

MEETING, Wednesday evening, April 6th. DR. J. C. WARREN in the Chair.

DR. J. LESLIE FOLEY read a paper on

MORBID CHANGES AND SURGERY OF THE NAIL,[1]

and exhibited diagrams representing the various diseases. The discussion, which followed the reading of the paper, was chiefly confined to the treatment of in-growing toe-nail.

DR. G. W. GAY believed that no operation for radical cure could give greater satisfaction than Cotting's operation. He also spoke of the value of the nitrate of lead in all fungous granulations, malignant or otherwise, and said that it would frequently remove them efficiently, quickly and painlessly.

DR. MIXTER emphasized the importance in Cotting's operation of removing enough tissue. He considered that there was more likelihood of too little rather than too much being removed.

DR. CHARLES PUTNAM spoke of a little device, which was occasionally of use in holding up the in-growing side of the nail.

[1] See page 301 of the Journal.

Dr. J. C. Warren called attention to the sort of shoe which a patient with in-growing toe-nail should wear; and stated that the great point was to have the heel held well back in place by a good steel shank and a tight lacing, so that the toes might be free from pressure from all sides. His experience had been that women are more subject to in-growing nail, than are men, and he was inclined to attribute this greater frequency in women to the use of high-heeled boots.

Dr. Warren then showed a patient upon whom he had performed three months previously the operation of

GASTROTOMY FOR THE RELIEF OF ŒSOPHAGEAL OBSTRUCTION DUE TO MALIGNANT GROWTH.

Dr. H. L. Burrell then gave a *résumé* of

FOUR MONTHS' EXPERIENCE IN MINOR SURGERY AT THE BOSTON CITY HOSPITAL.[1]

Dr. Gay had expected that Dr. Burrell would speak of the radical cure of *hydrocele* by the injection of the compound tincture of iodine. He, himself, had had excellent results from its use. The hydrocele should be tapped and after the fluid had escaped the tincture of iodine should be injected, and that in turn allowed to flow off, after which the patient could with no especial danger keep about as usual.

He also spoke of the probable frequency of *deep varices of the leg* and of the rarity with which they are diagnosticated in the so-called "painful legs."

Dr. Gay agreed with Dr. Burrell that cotton-batting was good for *padding splints*, but said that for the correction of deformity, something firmer should be used, and that perhaps old linen was the best thing to be had.

In regard to a diagnosis between a doubtful case of *Colles' fracture* and a *sprain of the wrist-joint*, he stated that he had frequently found that in fracture lateral pressure over the ends of the bones caused most pain, while with antero-posterior pressure the pain was more marked in sprains.

He thought that if the diagnosis was doubtful, and the patient was an adult, it was better to treat the case as though a fracture existed.

Dr. A. T. Cabot, speaking of the diagnosis between a *Colles' fracture* and a *sprain*, stated that his custom had been to determine whether the greatest tenderness existed over the joint or over the radius above the joint; and that if it was most marked over the joint the case was probably one of sprain, if over the bone one of fracture.

In the treatment of fracture he laid stress on the importance of letting the fingers free as early as possible, so as to avoid subsequent stiffness.

In the treatment of *chronic ulcers*, he spoke of the value of elastic pressure over an absorbent dressing. The pressure would squeeze out the fluid from the granulations, and this would be absorbed into the dressing.

Dr. M. H. Richardson said that the prominence on the palmar surface of the wrist, so frequently noticed after *Colles' fracture* was generally considered due to bony callus principally from the lower end of the upper fragment, rather than to any inflammatory exudation around the flexor tendons.

He considered that whatever splint was used, care should be taken not to compress the superficial veins more than necessary; and he did not doubt that much of the œdema so frequently seen was due to improperly distributed pressure.

He could not remember to have seen a case of *teno-vaginitis* in the flexor tendons. In his experience with this disease it had been confined to the sheaths of the first two extensor tendons of the thumb.

Dr. E. H. Bradford called attention to a steel sole for the palliative treatment of *flat-foot*. This sole, having been carefully made to fit the bottom of the foot and to press up the arch slightly, should be covered with leather a little larger than the steel sole, so that the sharp edges of the latter should be covered by the projecting edges of the former, so as to protect the foot. The whole should then be put inside the shoe.

Dr. Inches said that at his clinic at the Boston Dispensary the maximum length of treatment for a *Colles' fracture* was eight weeks. The mobility, however, was not in any case restored as soon as the splints were removed, as the inflammatory stiffness existed for a very long time.

Dr. S. J. Mixter, in the treatment of *ulcers*, preferred a dry dressing to a wet one, but he was cautious about using iodoform in chronic ulcers, on account of the danger of dermatitis.

Dr. Watson said that there was one principle in the treatment of *chronic ulcers of the leg*, which he thought hastened the healing process materially. The analogy was seen in the freezing of a sheet of water. If the water were smooth the skimming of its surface with ice went on more rapidly than if it were thrown into an uneven surface by the wind. In the same way if the surface of the ulcer were made flat and smooth, the epithelium would extend across it more rapidly than if, like the rough water, its surface were occupied by granulations, and the open surface were above or below the level of the surrounding skin, as in the exuberant or indolent ulcer respectively. It had, therefore, been his practice in such cases as required it to secure this condition by the application of a shield of sheet-tin on top of the ulcer to bring the surface even with the surrounding tissues. The dressing was known at the City Hospital as the "Tin dressing," and its method of application was as follows: The ulcer and surrounding surface were soaked in corrosive sublimate, 1 part to 4000, and thoroughly cleaned, a bit of protective was then placed upon the surface of the ulcer, covering a little more surface than the ulcer actually occupied, protective or some substance having a perfectly smooth surface was used in order that the new epithelium, which shot in from the edges over night, so to speak, should not be pulled off by adhering, as it did to cheesecloth or compress or anything having a meshwork woven surface. The tin made to fit the surface on which it was to lie is then placed on the protective, and the whole, as well as the surrounding tissues covered with a dry corrosive sublimate gauze dressing, which was held in place by an evenly-applied bandage extending from toes to knee.

Ulcers which had been lagging for days beforehand would often take a rapid start under this dressing.

In regard to the location of *teno-synovitis*, Dr. Watson said that he had seen it occur in connection with the tendons of the tibialis anticus, and with the tendo achillis.

Dr. H. W. Cushing, referring to the differential

[1] See page 297 of the Journal.

diagnosis between *Colles' fracture* and a sprain, stated that he relied principally on the relative positions of the styloid processes of the radius and ulna, and called attention to the fact that in fracture the styloid process of the radius is apt to be displaced somewhat upwards so as to be oftentimes on a level transversely with that of the ulna.

DR. CONANT spoke of the tendency of a dorsal deformity to occur as a result of this fracture, even after the splints have been removed.

As to the danger of dermatitis from the use of *iodoform*, he had found that it could be avoided by confining the iodoform within the limits of the raw surface.

DR. WARREN had also found an altered relation in the position of the styloid processes of the radius and ulna of use in making a diagnosis of a *Colles' fracture*.

He considered the breaking up of the impaction, a step of great value in the treatment. He used a grip which he had learned from Dr. R. M. Hodges. While the hand of the patient was firmly grasped by the same hand of the surgeon, the surgeon's other hand grasped the lower part of the forearm, just above the wrist, and the thumb exerted pressure over the lower end of the radius, and thus, by manipulating with the hand in this position, the impaction were broken up. His experience had led him to believe that the after deformity was rather apt to be lateral than anteroposterior, and that this deformity was best avoided by the early and careful placing of pads. He also referred to the excellent results following the judicious use of massage in the after-treatment of the stiffness following fractures near the joint.

As for *chronic ulcers*, he thought rest the most reliable curative agent, and referred to the practice of Malgaigne, who prescribed such enormous poultices that the patient could not get about, and was, therefore, obliged to rest. He would, however, not underrate the value of pressure.

DR. O. K. NEWELL demonstrated the facility with which short instruments could be introduced into the bladder, and in connection showed a

MODIFIED URETHRAL DIVULSOR.

Remarks were made by DRS. CABOT, WATSON and TILDEN.

[Special Report for the JOURNAL.]

THE NINTH INTERNATIONAL MEDICAL CONGRESS.[1]

SECTION ON GENERAL SURGERY.

GUN-SHOT WOUNDS OF THE ABDOMEN,

by DR. T. H. MANLEY, of New York.

The case was reported of J. C., brought into the Hospital with a pistol-shot wound of the abdomen, in the left epigastric region. The patient was seen two hours after the injury. The abdomen was greatly distended, and evidently contained fluid. The wound was probed with great care, but the place of entrance into the abdomen could not be found. An incision was then made in the linea alba. When the peritoneum was punctured, a large amount of blood escaped, estimated to be half a gallon. The hæmorrhage was found to come from a branch of the inferior mesenteric artery. This was secured with a ligature. A double perforation was found in the descending colon. This was closed with the Lembert suture, including only the serous and muscular layers. The bullet was not found. The abdominal incision was closed and dressed antiseptically. It, however, failed to unite. In other respects the patient did well. The incision was again closed, the peritoneum being united with a separate row of sutures and the other layers with silver wire. On the third day it was found that the central portion of the wound had opened, but that the peritoneum had united. The patient eventually recovered completely.

The speaker then made some general remarks with reference to operations upon the abdomen. Severe shock should be a contraindication. Nothing will justify laparotomy when shock exists, except positive evidence of hæmorrhage. Opening of the abdominal cavity in man is a much more serious operation than in women. Man habitually uses the abdominal muscles in breathing, while in woman, the type of breathing is thoracic. This interferes with the union, and thus tends to make ventral hernia more common in man. In man, the abdominal incision should be no longer than necessary. For exploratory purposes, the incision through the linea alba is the best. The drainage-tube can serve no useful purpose in the healthy peritoneum free from septic contamination, and does interfere with union. Antiseptics should be always used until it is shown that cleanliness will render septic poisoning impossible.

THE USE OF THE GALVANO-CAUTERY SOUND, PARTICULARLY IN HYPERTROPHY OF THE PROSTATE, WITH REPORT OF CASES.

by DR. ROBERT NEWMAN, of New York.

The instrument consists of a smooth sound, with a fenestrum at its lower extremity. At this opening is a piece of platinum wire, in connection with a galvano-cautery battery. By pressing a key in the handle of the sound, the platinum wire is heated to a bright red color. This does not destroy tissue. The instrument is introduced until the lower extremity reaches the prostate gland, when the current is passed through the platinum wire. These applications are repeated at intervals of three to five days. The author has employed this method of treatment in fifteen cases, seven of these being cases of hypertrophy of the prostate gland. In all these instances there was improvement in the symptoms presented, and a decrease in the size of the prostate.

The next paper was entitled

ENDO-CRANIAL SURGERY,

by PROFESSOR DURANTE, of Rome, Italy.

(The paper was read in French.)

BONY UNION AFTER INTRA-CAPSULAR FRACTURE OF THE NECK OF THE FEMUR,

by DR. CARNOCHAN.

The reader presented the specimen from a case of fracture of the neck of the thigh bone, occurring in an old lady seventy years of age, in which bony union followed rest in bed for a period of nine months.

DR. MORRIS, of New York. The treatment by rest in bed is not to be recommended as a general practice in cases of intra-capsular fracture of the femur. Unless the fracture is an impacted one, there is no hope of union, and the sooner these patients are gotten out of bed the better.

[1] Concluded from page 288.

UNUNITED FRACTURE OF THE FEMUR SUCCESSFULLY TREATED BY DOUBLE SPLICE AND WIRED CLAMP,

by DR. F. LEMOYNE, of Pittsburg.

The method of treatment described had been employed in three cases. In two cases the humerus was the seat of operation, and in the third, the case to be described, the femur was the bone operated upon. The patient, a man aged thirty-seven years, was struck by a bucket of ore, receiving a fracture of the left femur, about its middle. This was treated in the usual manner, but union failed to take place. The various procedures employed in cases of ununited fracture, such as drilling, cutting off the ends and wiring, were tried, but no union followed. Eight months after the accident, the mobility at the seat of fracture was very distinct. The seat of fracture was then exposed by two incisions, one on the anterior, and the other on the external aspect of the limb. The fragments were found attached by firm bands of fibrous tissue, and the bone-tissues were softened. The fragments were completely separated, and the intervening tissue cut away. The lower extremity of the upper fragment was then sawed off, so as to form a wedge-shaped piece. The upper end of the lower fragment was sawed, so as to have a corresponding V-shaped depression. The extremities were then brought into apposition. A hole was made in each fragments so that the two openings were two and one half inches, apart. A steel clamp, its extremities being bent at right angles, was laid upon the anterior surface of the femur, the ends being inserted into the holes already prepared. This was secured to the bone by three bands of wire encircling the limb at the seat of fracture. The limb was placed upon a posterior-inclined plane, the foot being elevated about eight inches. Sole-leather splints were applied on the external, anterior, and internal surfaces, and the patient was kept as quiet as possible. High inflammatory action, with free suppuration, occurred. In five weeks there seemed to be some union, and the clamp and wire were removed. The wound was still kept in leather splints. One year after the operation, there was good union. The patient could bear his entire weight on the limb. There was, however, shortening to the extent of two and one-half inches.

DISCUSSION.

DR. T. H. MANLEY, of New York. I have had considerable experience in wiring the shafts of bones, particularly in fractures of the thigh. If there is much shortening, I think that we should wire the bone at once. We do no harm by making a free incision down to the bone, and the silver wire causes no irritation. I leave them in permanently, and the results have been satisfactory.

WIRE EXTENSION SPLINTS IN THE TREATMENT OF FRACTURES NEAR THE JOINTS,

by DR. GIBSON.

Several wire splints, intended to be used in the treatment of fractures of the thigh, fractures near the head of the humerus, and Colles' fracture, were exhibited. The author claimed for these, efficiency and comfort. He recommended their use more particularly in cases of fracture near the joints.

DR. MYERS, of Fort Wayne. I think that the best dressing for fractures that we now have is plaster-of-Paris and crinoline. When properly applied immediately after the reception of the fractures, it answers every purpose. It is less inconvenient than other dressings, and the results obtained are satisfactory.

SPLINT FOR FRACTURE OF THE LOWER JAW,

by DR. S. S. KOSER, of Williamsport.

The speaker reported a case in which the lower jaw was fractured through the symphysis and one inch left to the symphysis, with separation of both processes on the left side. Various forms of splints were tried without satisfactory results. An intra-dental splint was then made to which was attached steel arms projecting from the sides. An external rubber splint was then made and the two splints secured together. This held the fragments in position, and good union was obtained.

DR. ALBERT B. STRONG, of Chicago, exhibited drawings taken from the photographs of

FROZEN SECTIONS OF THE MALE PELVIS,

showing the relations of the peritoneum to the bladder, the rectum and the median line of the abdominal wall with special reference to supra-pubic cystotomy.

The Section then adjourned.

FRIDAY — MORNING SESSION.

The first paper was entitled,

A NEW METHOD OF OPERATIONS ON BONE,

by MILTON J. ROBERTS, of New York.

The author demonstrated his electric osteotome which consists of an electric motor to which may be attached trephines and circular saws of various sizes. By means of an attachment a saw is used having a to-and-fro movement. The motor is run by a storage battery. There is also an electric light with a mirror attached to the motor by which light is thrown on the part operated upon. In addition, there is also a spray apparatus operated by compressed air by which a constant spray is thrown upon the saw while in operation. This is found to facilitate the cutting. All the various attachments are under the control of one hand.

CALCULUS, IN SYRIA.

by Dr. GEORGE E. POST, of Beirut, Syria.

Stone is a common affection in almost every part of Syria and Palestine, but more frequent in certain villages than in others. The proportion of large stones is greater than it is either in Europe or America. This is to be explained by a number of causes; among others, the prejudice against surgical operations, the want of skill on the part of the surgeons, the ignorance with reference to the use of the sound, and the poverty and ignorance of the people, leading them to postpone operation as long as possible. To these is to be added the traditional faith in the solvent power of certain substances. The native surgeons, in operating, practice median lithotomy; the patient is placed on his back in the lithotomy position, without anæsthetics, and one or two fingers are introduced into the rectum. The stone is pushed forward with the fingers until it impinges on the perineum. The operator then cuts with a razor or a scalpel directly on the stone, the cut extending from a little behind the scrotum to within the anus, laying open not only the perineum, but also the lower portion of the rectum, and the stone pops out. This method of operation is of course productive of many cases of fistula of various kinds. There is also considerable risk from hæmorrhage. In one

case operated on in this way in infancy, the author found three stones in the scrotum and two in the perineum.

The largest stone removed by the speaker weighed about twelve ounces. It was four inches in length, three and one-half in breadth, and nearly two inches in thickness. This stone was removed by perineal lithotomy, and it was necessary to cut the prostate on both sides and also in the middle. The patient from whom this stone was removed did well for fifteen days, when as a result of imprudence in diet he was attacked with a colliquative diarrhœa and died seven weeks later from exhaustion. There was no unfavorable symptoms connected with the wound. The greatest number of stones removed from one patient was two hundred, but many of these were merely granules. In one case there were eleven stones of nearly equal size, and weighing in the aggregate about six ounces.

The author had operated on 250 cases. Less than one-half of the stones were composed of phosphates; over one-third consisted of uric acid and urates, and of the remainder the most consisted of oxalate-of-lime with a few carbonate-of-lime stones. One hundred and seventy-six of these cases were operated on by perineal lithotomy. Of this number ten cases proved fatal, 106 of the 176 were in children less than ten years of age. Two of these children died. One of erysipelas and the other of shock. The remaining 70 cases were between eleven and seventy-five years of age, and of this number eight died; four of the fatal cases were between sixty-five and seventy-five years of age. In 44 cases lithotrity was employed with a fatal result in four instances. Of the 250 cases eleven of the patients were females.

Two cases of urethral stone were reported. The first was that of a man of seventy, with phimosis. A stone was found at the meatus and removed. A second was found four inches from the meatus. This was also removed; a third stone was detected in the membranous portion of the urethra, but during the manipulations it passed into the bladder. Two or three days later it was caught with a lithotrite and removed. The second case occurred in a child two years of age, who was brought to the speaker on account of total retention of urine. The distended bladder reached above the umbilicus. An obstruction was found at the neck of the bladder, but it was found possible to pass a catheter over the obstruction. The urine was drawn for several days. It was then decided to make an exploratory section, but when the time for operation arrived, it was found that the stone had been dislodged and was at the meatus. It was then removed without difficulty.

DISCUSSION.

DR. J. A. S. GRANT (Bey) of Cairo, Egypt. I have listened with much interest to the paper, and it may be of interest to say something with reference to stone in Egypt. This is a very common affection in Egypt, where we have another common disease, that is, bilharzia hæmatobia. Certain investigations seem to show that the germs of this disease have something to do with the causation of stone. Sections of calculi have revealed the presence of the germs of this affection. The following case recently presented himself to me, The patient, a railroad employé, came with considerable inflammation of the scrotum and with a fistulous opening entering the scrotum. A large scrotal calculus could be readily seen. Six years previously the patient had suddenly had complete retention of urine. This continued ten days, and the trouble then suddenly disappeared. After this he noticed that the scrotum was gradually increasing in size. I made a large incision through the fistulous opening and removed from the scrotum a stone weighing fourteen ounces.

In Egypt we do not have the class of stone cutters referred to by Dr. Post. Egypt is divided into fourteen provinces, each of which has a hospital under the charge of a competent physician.

DR. OSCAR J. COSKERY, of Baltimore, reported a

CASE OF AN UNCOMMON FRACTURE WITH DISLOCATION OF THE TARSUS AND METATARSUS.

ELASTIC CONSTRICTION OF THE NECK WITH EXCLUSION OF THE TRACHEA AS A MEANS OF CONTROLLING HÆMORRHAGE IN OPERATIONS ON THE HEAD,

by DR. SENN, of Milwaukee.

The author referred to the many advantages derived from the use of the Esmarch bandage in operations on the extremities. In the case of the head where bloodless operations are most desirable we have, so far, not been able to attain that result. The principal objection to constriction of the neck appears to be the necessary compression of the trachea. It is also possible that the pressure on the pneumogastric and phrenic nerves may interfere with respiration. The author had taken dogs, and isolating the trachea, has passed an elastic bandage around the neck between the œsophagus and the trachea. This produced no immediate effects on respiration. In one case the dog was allowed to live two hours with the band around the neck and no blood going to the brain with the exception of that which reached it through the vertebral arteries. This animal was allowed to live and presented no subsequent symptoms. It was found that after the band was applied the lingual, the external, the internal and the common carotid could be divided without any escape of blood from the proximal extremity. The only arterial hæmorrhage was from the peripheral end through the collateral circulation. There is some venous engorgement, and as a consequence a certain amount of venous bleeding. By this method we can extirpate the tongue, excise the upper jaw, perform radical operations on aneurisms, especially on aneurisms by anastomosis, and do other operations that could not be done without it.

CONGENITAL DISLOCATION OF THE HEADS OF THE FEMORA,

by DR. CARNOCHAN, of New York.

Reference was made to the general lack of knowledge concerning this malady. The affection is, however, not an infrequent one. The author had seen seventy cases during the past twenty-five years. Drawings from several cases of this kind were exhibited, showing the peculiar deformity which this malady produced. The pelvis and femora taken from an individual sixty years of age, who was the subject of congenital dislocation at the hip-joint was shown. There were marked changes in the structure of the heads of the thigh bones and also in the acetabula, which were simply triangular cavities. As to the cause of this condition, it was uncertain whether it was due to rough handling or to want of nutrition.

DISCUSSION.

DR. MORRIS, of New York. It is evidently not due to rough handling, for it is quite frequent in the Northern part of Germany, where women receive skilful attention during confinement. The deformity is quite frequent where rachitic affections abound.

DR. GEORGE E. POST, of Beirut. I see this condition quite frequently. While one class of cases may depend on rachitis there is another class in which the condition is evidently the result of mechanical causes. In a recent case I found the head of the femur in the thyroid foramen; there was no history of injury. I can only explain these numerous cases disassociated from scrofulous and rachitic affections as due to some movement of the child in utero.

DR. SPANTON, of Hanly, England, exhibited a

PAD FOR RETAINING THE DISCHARGES IN CASES OF FÆCAL FISTULA.

DR. ARTHUR H. WILSON, of Boston, illustrated with the stereopticon, certain

HISTOLOGICAL PATHOLOGICAL CHANGES IN THE PROSTATE GLAND.

The last paper was entitled

ALCOHOL AS AN ANÆSTHETIC

by DR. JOHN E. LINK, of Terre Haute, Ind.

After an experience of twenty years, the author recommended the use of whiskey as an anæsthetic. He advised the use of full-proof whiskey at least two years old, giving from one to two ounces repeated every three to five minutes according to the rapidity of the absorption. The quantity given varies between sixteen and twenty-four ounces. The patient is then allowed half an hour to quiet down. If the desired effect is not produced a few inspirations of chloroform are given. The two agents combined give better results than either alone. A number of cases in which this method was employed were reported.

DR. KOSER, of Williamsport, offered a resolution to be forwarded to Professor Bilroth, congratulating him upon his recovery from his severe illness; adopted.

After extending a note of thanks to the President, the Section adjourned *sine die*.

AMERICAN GYNÆCOLOGICAL SOCIETY.[1]

TWELFTH ANNUAL MEETING.

TUESDAY. — FIRST DAY. — AFTERNOON SESSION.

IS SALPINGITIS TO BE TREATED BY EXTIRPATION OF THE TUBES AND OVARIES IN ALL CASES.

by DR. W. M. POLK, of New York.

By salpingitis the speaker meant that disorder whose most marked clinical expression is found in the presence of the peri-uterine masses so commonly met with in palpating the pelvic contents. The most common result of this condition is displacement of the tubes. The author had already made a report on one hundred cases of salpingitis. In fifty of these cases the abdomen was opened, and in fifty no section was made, but in these a comparison of the results of careful examination left no doubt that the whole series of one hundred cases represented the same disease. The majority of cases of salpingitis recover. Even where a small quantity of pus is present this may be encapsuled by lymph and do no harm. Some of the cases remain as confirmed invalids, while a few die. Outside of the puerperal condition the death-rate is low, and including antiseptic midwifery the death-rate is still low. The main symptom observed was dysmenorrhœa.

An examination of the cases coming under the author's observation led him to believe that the chief cause of the symptoms in many cases was the presence of adhesions. He had operated, removing the adhesions, but allowing the tubes and ovaries to remain, on the ground that although pregnancy might not occur, yet as their removal was unnecessary, mutilation could be avoided and one of the objections to the operation removed. The question whether or not the adhesions will re-form, must be answered by experience. The author reported eight cases operated on in this way. In case I, there was shortened utero-sacral ligaments, the posterior fossa of the uterus touching the rectum. The ligament was stretched, a drainage-tube inserted, and the patient did well. She had suffered for a long time from dysmenorrhœa and pain during coition, and other evidences of so-called cellulitis or chronic salpingitis. In the second case the uterus was retroverted and bound down by adhesions. These were torn, the tubes and ovaries loosened, and the uterus held forward by Alexander's operation, the object being to displace the uterus from its old position and prevent the formation of new adhesions. Within proper limits, the extirpation of the tubes and ovaries is a valuable operation. It is, however, desirable to confine it within its narrowest limits, and where it is possible to avoid mutilation, to do so.

DISCUSSION.

DR. A. MARTIN, of Berlin. We can only progress in this important matter by distinguishing between the different forms of disease of these organs. Ten years ago, I pointed out the anatomical forms of these different affections. In only a small number of cases is the tube the seat of a neoplasm. I have found only one case of carcinoma of the tube. The most frequent disease of the tubes is catarrhal inflammation, extending from the uterus. We frequently see it following the puerperal state. It has often been supposed that the salpingitis was of gonorrhœal origin, but only in a few instances have the gonococci been found in the tubes. In most cases the disease of the tubes is a simple benign affection; a catarrh which increases the size of the tube and may give rise to hæmorrhage, particularly at the time of menstruation, and occasionally to pyo-salpinx. Frequently, early occlusion of the tube is the result.

Only a small number of the two hundred and fifty cases coming under my observation have required operation. As in most cases the disease is a simple catarrh, we must first institute treatment adapted to the simple nature of the affection. If we do not succeed in relieving the symptoms and reducing the size of the tube, we are to operate. I have done eighteen operations for disease of the tube, but very seldom did the tube give me the occasion for the operation. Generally it was the spread of the disease to the other pelvic organs, particularly the ovaries. In many cases there was abscess of the ovaries. This severe complication is not observed with sufficient frequency as to warrant operation in all cases of salpingitis.

[1] Continued from page 290.

In operating in these cases, I puncture the tube before removing it. I do this because purulent matter often escapes into the peritoneal cavity from rupture of the tube. I cannot say that my statistics are as favorable as some. I have lost about twelve per cent. I never perform the operation except where there is a distinct tumor. In nearly all of the cases there was severe peritonitis. In the majority of cases, we can cure these patients by general treatment.

DR. T. A. EMMET, of New York. I hold much the same views as Dr. Martin. A large number of these cases can be cured by careful general treatment, and it is our duty to operate in no case until the woman has had an opportunity to see whether or not she can get well without operation. Where the disease of the tube is unquestionably of gonorrhœal origin, the operation may be resorted to at once. I am satisfied that two-thirds or more of the cases operated on to-day, will not be operated on five years from this time.

DR. WILLIAM GOODELL, of Philadelphia. I agree in a large part with what Dr. Martin has said. My rule is, to try in the majority of cases the effect of rest treatment, with general and local medication. It seemed to me that the author gives us an operation more dangerous than removal of the ovaries. What objection is there after the abdomen is opened, to the removal of the ovaries and tubes? This is not a mutilation. They are unable to perform their functions. Rather than resort to a second operation, such as Alexander's, I should favor the removal of the tubes and ovaries.

In cases of mal-position of the uterus, associated with disease of the tubes and ovaries, I have frequently righted the uterus, by introducing a pessary at the time the ovaries and tubes have been removed, and keeping it in during the process of recovery. The pessary may then be removed and the uterus keeps its position. I have had cases which improved temporarily under rest treatment, but in which I was finally compelled to resort to operation.

DR. G. BANTOCK, of London. The question which has been proposed, may be answered in the negative. My views have been well expressed by Dr. Martin. I never contemplate the removal of the ovaries without a great deal of anxiety. Ordinary cases of salpingitis, due to catarrh, can be cured by rest and constitutional treatment. When we come to pyo-salpinx and hæmato-salpinx, the conditions are different. A well-marked case of pyo-salpinx, whether due to catarrh or to gonorrhœal infection, will require operative treatment. I have, however, seen tubes which evidently had contained a large quantity of pus, but which when examined, contained only a small quantity of cheesy matter. It is rare to have death from the rupture of a pyo-salpinx. In hæmato-salpinx the condition is far more serious than in pyo-salpinx.

About one year ago, I had under treatment a case of fibroid tumor of the uterus. The patient suffered a great deal of pain, and I was induced to operate. I found numerous adhesions, and when I reached the brim of the pelvis, the adhesions were so numerous that I could not proceed. I therefore determined to remove the ovaries, and bring about the menopause. The left ovary was removed without difficulty, but when I came to remove the right ovary, it could not be found. Fluid was detected in the right side, and an incision showed that there was a fibroid tumor which had undergone cystic degeneration. The edges of the cavity were stitched to the abdominal wall, a large opening being left to facilitate drainage. In three months the patient was quite well. She subsequently married, and, a short time ago, was delivered of a living child. It is, therefore, clear that when the mischief arises from the outside of the tube, sterility does not necessarily result. When, however, the inflammation begins inside, sterility will probably be induced.

DR. R. S. SUTTON, of Pittsburgh. I agree that all cases of salpingitis should not be operated on, but if pus exists in the Fallopian tube, it is our duty to evacuate that pus, just as it is our duty to evacuate a collection of pus in the arm. No one has a right to allow a woman to go around with a pus-sac, ready to burst into the peritoneum, when we can remove it. The condition of life of the patient must be considered. A poor woman may require operation, while a rich one might be able to get along without operative measures.

DR. GILL WYLIE, of New York. In one thousand of my earlier cases of peritonitis and cellulitis, I operated about once in every ten cases. In later years, the proportion has increased. Of my last sixty cases, sixty per cent. were for pyo-salpinx, and all these cases have recovered. I should not be willing to try the operation suggested by the author.

DR. WM. M. POLK, of New York. The question which I considered was in regard to mutilation. A woman has a right to the ovaries if they do her no harm. Dr. Bantock's case shows that the presence of adhesions is not a bar to pregnancy. I think that the removal of the tubes is a most important operation, but we must avoid extirpation of the tubes and ovaries unnecessarily.

DRAINAGE AFTER LAPAROTOMY,

by DR. PAUL F. MUNDÉ, of New York.

While drainage is an accepted procedure in general surgery, its position in abdominal surgery is not yet settled. The author then quoted the opinions of various operators, showing the great diversity of views. If antiseptics can prevent the decomposition of fluids left in the abdominal cavity, the use of the tube can be dispensed with. So long as there is any doubt as to this, so long, at least theoretically, will drainage be called for. Some of the disadvantages connected with the use of the tube are: that the abdominal wound cannot be completely closed; there is danger of septic contamination through the tube; the liability to ventral hernia is increased; and there may occur serious reflex gastric irritation. Whatever good is done by the drainage-tube is probably accomplished within the first twenty-four hours. As soon as the fluid which escapes is serous or sero-sanguinolent, the tube may be removed. It has recently been recommended that, in cases where it is found impossible to remove the whole tumor, and a large cavity is left, a sac of iodoform gauze be made, and packed into every crevice of the cavity. This is then filled with narrow strips of iodoform gauze. This the author had employed with satisfaction. At the end of ten days, the dressing was perfectly odorless.

It was thought that when drainage seemed necessary, that the tube might be omitted, and the removal of fluid accomplished by an antiseptic gauze strip passed through the vaginal roof into the vagina. This permits of the perfect closure of the abdominal incision.

DISCUSSION.

Dr. A. Martin, of Berlin. I do not employ drainage after ovariotomy, for the absorbing power of the peritoneum is so great that it can dispose of a considerable quantity of fluid. I use drainage in only a few conditions. I use it when I remove the uterus by amputation through its neck. I use it in vaginal hysterectomy. I use it where there are large surfaces of a sloughing character, and large cavities left in the broad ligaments, as in extra-uterine pregnancy, in large fibroid tumors which have been enucleated, and in large cystic tumors, where all the surfaces cannot be brought in contact. In these cases I use the drainage-tube, passed through Douglas's cul-de-sac into the vagina, as I consider it important to close the abdominal wound.

Dr. G. Bantock, of London. So confident am I of the value of drainage, that I use it on the slightest provocation. I use it where there has been abundant adhesions, and where it is found impossible to completely dry the peritoneal cavity. I use it where the tumor has been burst, and it is impossible to remove all the contents. In these cases, I use large quantities of clean, warm water. I have given up everthing in the form of antiseptics. Since I have given up the antiseptic method, my results have correspondingly improved. In my last one hundred and four ovariotomies, I have lost three, and in the last seventy-eight I have lost one. While I value the use of the tube, I do not think that it is required in the majority of cases of ovariotomy.

The form of the tube is of importance. I employ the ordinary straight drainage-tube, to be introduced to the bottom of the wound. It should be emptied every two or three hours. This prevents any absorption of the effused fluids, and the patient recovers without any elevation of temperature, or any alteration in the pulse. When the fluid removed is nothing but plain serum, the tube may be taken away; but if it is removed before all blood has disappeared, great risk is run.

Dr. Gardiner, of Montreal. In thirty-five abdominal sections, I have used the drainage-tube in about sixteen cases. In sixteen ovariotomies, I employed it in eight or nine cases. I shall continue to use it until further experience gives me some reason to lay it aside.

Dr. Gill Wylie, of New York. One of the advantages of the use of the tube has not been referred to, and that is that it gives us early information as to the occurrence of hæmorrhage.

Dr. William Goodell, of Philadelphia. I am not a believer in the drainage-tube, although I do use it occasionally. In three or four cases, I have had colloid cysts rupture three or four weeks before operation, and when the abdomen has been opened, all the organs have been found covered with the colloid material. These cases recovered without the use of the drainage-tube. This was before the time of washing out of the abdomen. In a recent case of the same kind, I used the drainage-tube, and not more than three ounces of fluid escaped. I agree with reference to the great value of the tube as showing the presence of hæmorrhages. In one case a fæcal fistula occurred, and this I attributed to the presence of the tube.

Adjourned.

THE POTATO IN ITS RELATION TO IRELAND'S MISERIES.

An anonymous writer in the *Westminster Review*, speculates as to the causes of Ireland's wretchedness. It is not over-population, for Ireland supports fewer people per square mile than England and Wales, Switzerland, France, Belgium, Saxony, or the Netherlands. It cannot be the lack of fertility of the soil, for the land of Ireland is proverbially productive. Nor can it be said that the aggregation of people in the land is the cause, for whilst Belgium, with only three and a half million acres under cultivation, supports one million of people by agriculture, Ireland employs but one million one hundred thousand for the cultivation of fifteen and a quarter millions of acres. Various other unfavorable conditions are suggested as accounting for Ireland's distress, but the reviewer regards as of the first importance the matter of diet. The Irish, as a nation, are miserably fed. To great multitudes of the Irish, the potato is almost the only means of sustenance. Now it is easy to show on physiological principles the impossibility of a nation thriving on potatoes. The writer fortifies his argument by citing tables from recent dietary works, showing the meagreness of potatoes in nitrogen and comments on the unfortunate choice which the Irishman has made in adopting as his staple food one of the worst vegetables grown — "a vegetable which does not furnish either sufficient carbon or nitrogen, except it be eaten in such inordinate quantities as to produce a sense of fulness which is not compatible with labor." "To eat twenty-four pounds of food each day in order to produce the same amount of energy as can be obtained from a couple of pounds of other articles low in cost and equally appetizing, can scarcely be called economy.

"A consideration of the dynamic value of foods leads to the same conclusion. Bread or oatmeal, to the value of three pence half-penny, would raise one hundred and forty pounds to the height of ten thousand feet, whereas five pence half-penny would have to be spent on potatoes for the same work. This, however,

takes no account of the nitrogen, of which element the potato is singularly deficient, and does not consequently give the true dietetic value of that root. In comparison with the cereals, it may be said roughly to be eight times as expensive to live upon potatoes as upon bread or meat. It must further be borne in mind that although the yield per acre of potatoes is of much greater value than that of wheat, the cost of growing the one (exclusive of rent rates, tithes and taxes) is within a fraction of double the cost of growthe other."

The reviewer refers to historical facts which show that far-sighted political economists predicted untold calamities for Ireland as the result of her too exclusive cultivation of the potato. William Cobbett foretold that the ruin of Ireland would be the cultivation of "that dirty root." "But before Cobbett, Adam Smith wrote on the adoption of the potato as the national food in a manner . . . which showed a complete grasp of the subject. He believed that the same extent of land which would grow food for one person in England would support four in Ireland . . . but *how* support? History furnishes the answer. While the people of England have been steadily progressing, living in increasing comfort as the years roll by, the people of Ireland have as steadily lost ground, the population decreasing, the number of paupers every year increasing, the housing of the masses becoming more wretched, their comforts fewer, famines more frequent; and as the natural result, popular discontent has long since reached a state which may be called chronic, and that which we call *agitation* is little more than the heart-rending cry of a generous people who live on the verge of starvation, with no prospect of immediate improvement, and absolutely no hope of the future."

Adam Smith deprecated the adoption of a potato diet for the following reasons: (1) Being incapable of storage, the cultivation produces dependence upon a single year's crop; (2) Scarcity and famine must therefore be of more frequent recurrence than would result from any other diet; (3) Its low value as a food must bring down the wages of the people to the standard of their diet; (4) Its bulk and weight render it unfit, in a large degree, for cultivation as an article of export.

A quotation from Smith (for which we are indebted to the reviewer), well illustrates these points. It is remarkable, by the way, how completely history has verified the theories of this great political economist; we need only to refer to the famines of 1846, 1854, and subsequently, with the wasting diseases which followed in their train, the enormous emigration draining the country of its very life-blood, and other national evils, physical and moral, making the evolution of the Irish people, during the greater part of this century, retrogressive rather than progressive.

"It is therefore of the utmost consequence to the well-being of every people and to their protection in years of scarcity, that they should not subsist principally on the potato. In Great Britain, the pressure of a scarcity is evaded by resorting to an inferior species of food and a lower standard of comfort; but if our people were habitually fed on the potato, this would be impossible. The chances of famine would thus be vastly increased; while, owing to the low value of the potato as compared with most other things, the laborers would have far less chance of acquiring a taste for animal food or other necessaries and luxuries, and consequently, of changing at any future period their actual condition for the better. For these reasons, it would seem that the rapid extension of the potato culture is by no means the unmixed benefit it is regarded by some."

Buckle, in 1859, wrote on the influence of climate and soil — the external environment generally — on the welfare of nations, and his work made a profound impression at the time, and many of his generalizations are regarded as just as true to-day as they were regarded bold and questionable when he wrote his "History of Civilization in England." Buckle, in showing that the spirit and character of a people are dependent on material circumstances did indeed touch upon diet but only incidentally and incompletely; it remains for some future philosophic historian, with a knowledge of physiological chemistry, from the same standpoint, to pursue the work of Buckle, and show the rôle of food in modern civilization. The material for such a survey is accumulating, and our countrymen, Atkinson and Atwater, are already making use of it.

TRANSFUSION AND INFUSION.

THE brilliant successes in saving life already reported have fully established the value of this method of relieving the alarming and dangerous condition of acute anæmia following excessive hæmorrhage, and have incited many experimenters to renewed investigations, which have added much important information to our previous knowledge of this subject.

The danger of direct transfusion, and the difficulty in obtaining a donor for this purpose, made it exceedingly desirable to discover some substitute equally efficient, and more easily controlled.

For this purpose Lauderer with Cohnheim in 1881,[1] made a series of experiments with the alkaline salt solution; but the conclusions arrived at were that its effects were transitory and unsatisfactory. Experiments with defibrinated blood were more successful; but the best results were obtained from a combination of defibrinated blood (1 vol.) with an alkaline salt solution (3 to 4 vols.) Animals which had suffered a blood loss of 5.3 per cent. of their bodily weight, and a case of severe nitro-benzole poisoning were successfully resuscitated. Schramm[2] has shown that a loss of blood equalling 5.4 per cent. of the bodily weight almost invariably results fatally, and fourteen experiments with infusion corroborated the above statement that the salt solution caused only a moderate and transitory cardiac irritation, and had no decided influence in preserving life after severe hæmorrhages. A summary of Schramm's work gives: Blood transfusion, 10 cases; blood loss, 5.3 per cent. 10 recoveries; infusion, non-defibrinated blood 1; salt so-

[1] Virchow's Arch., cv. 2, p. 351, 1886.
[2] Wien. Med. Jahrb., 4, s. 489, 1885.

lution 4; 10 cases, 5 deaths, 5 recoveries; infusion of serum or egg albumen and salt solution, 17 cases, 9 deaths, 8 recoveries, the albumen having apparently no effect in regenerating the blood.

He then concluded that the treatment of acute anæmia from hæmorrhage should be thus classified: (1) Analeptics; (2) salt solution infusion; (3) in cases of renewed collapse, blood transfusion.

Lauderer has, since his original report,[3] continued his efforts to find a substitute for human blood, and his more recent experiments[4] with an alkaline salt-sugar solution, show[5] more favorable results than with the simple salt solution originally used. He treated successfully a case of acute anæmia in a human subject, and demonstrated that animals treated in this way would recover after a blood loss of 5.5 per cent. even, which is strong proof of its efficacy. Experiments on animals poisoned with nitro-benzole and chloral were also successful.[6] The advantages claimed by Lauderer for this solution are: (1) That the fluid constituents of the tissues (Gewebssäfte) are energetically attracted to the blood. (2) That the blood tension is essentially increased: a very important factor in hæmorrhage. (3) The addition of an easily assimilated nutritive substance; namely, sugar, for which purpose the simple salt solution generally used, or even blood, has been shown valueless.[7] At the discussion of Gaule's report Krönlein's remarks referring to his own experience with infusion[8] confirmed Lauderer's views. Krönlein also classified the indications *ut. seq.*: (1) Altered vascular tension; (2) altered nutrition of tissues; (3) interference with the function of the hæmoglobin. In the two later he considers that infusion of simple salt solutions is valueless. In (3), for example, carbonic acid poisoning, blood transfusion would be required; but this view is somewhat at variance with Lauderer's ideas, who considers that even in this class of cases blood transfusion is not necessary. The fact that recoveries have followed infusion of the six per cent. salt solution, in cases of severe post partum hæmorrhage, Lauderer does not think invalidates his conclusions, since the best results with this solution have been obtained in this class of cases, a fact which he considers quite significant.

In regard to the details of the operation of infusion Cohnheim strongly recommended that the solution should be infused into the proximal end of a distal artery, preferably the radial. His reasons for advancing a method so entirely different from the usual operation[9] are that the artery is more readily found, the blood current in the artery diminishes the danger of a sudden over-powering of the heart; the danger from air embolism is avoided, and the opportunity for gangrene induced by rupture of distal arterioles during spasm to resist a foreign fluid is absent. It is singular that these suggestions endorsed as they were by an investigator of Cohnheim's reputation should have received so little attention, for, as far as we know, there is no published case where this method has been employed. It would seem as if these advantages were not wholly theoretical.

The possibility of relieving dangerous collapse from other causes than excessive hæmorrhage, probably suggested by the above investigations, has led to the development of infusion, and its applications to other emergencies than those for which it was originally intended.

Among these is the work of C. Sanquirico,[10] of Siena, who has attempted to show by experimentation that the elimination of fatal doses of poisons through the renal excretion can be so accelerated by the introduction into the vascular system of an "indifferent" solution equivalent in amount to eight per cent. of the animal's weight, that life can be saved. He succeeded only where chloral hydrate and aconite were the toxic agents employed. Also, the treatment of cholera by subcutaneous infusion, first mentioned by Cantari (1865), and again revived by S. Samuel,[11] of Königsberg, is another outgrowth of this method. It is used in the stage of asphyxia, and is continued as long as the attack lasts; that is, until the pulse regains its force, and renal excretion is re-established. It has been found that the neck and intra-clavicular region is most favorable for the infusion, since the circulation and power of absorption exist in these regions after they have ceased in localities more distant from the heart, especially the extremities, and the technique of the operation is described most fully by Keppler,[12] who has apparently done the most accurate work in this subject. For a full statement of his experience and its results, those interested are referred to his publication.[13] Also, Samuel's article is a very valuable one to those wishing to gain a knowledge of the history and present value of this method.

From the above, it can be readily seen that we have at hand a means of saving life, where formerly the surgeon was compelled to sit with folded hands, and acknowledge himself powerless to aid his patients. Since then, the work of a few men has developed a means of treatment which has already proved effectual in many of these most trying cases. It surely behooves every practitioner to become thoroughly familiar with the treatment most valuable in these emergencies, and be ready to thus save many a victim who would otherwise perish.

CHOLERA AT THE PORT OF NEW YORK.

When the steamship *Alesia*, of the Fabian line, bound to New York from Naples and Marseilles, arrived at quarantine on September 23d, it was found

that eight persons had died of Asiatic cholera on the voyage to that port, and that eight others were suffering from the disease. Ever since the cholera began its ravages in southern Europe, every precaution has been taken to prevent vessels from the infected ports slipping by the quarantine authorities with the disease on board, and no case of it has been discovered until the arrival of the *Alesia*. There were five hundred and sixty-one steerage, and three cabin passengers. The eight cholera patients were at once removed to the hospital on Swinburne Island, and the other passengers to Hoffman Island, where they will be carefully watched and will be retained until all danger of their bringing the pest into the city is over.

The *Alesia* sailed from Marseilles on August 28th, and afterwards touched at Naples where cases have occurred during the latter weeks, doubtless transmitted thither from the neighboring town of Messina. At Naples she took on some three hundred additional passengers, of whom two are said to have been ill at the time. It was not until the ship had passed Gibraltar that they were isolated, and on September 13th, a third passenger was taken down with the disease. Among the victims who died on the voyage were the two original cases and also two of the sailors.

The steamship *India*, which sailed from Mediterranean ports one day ahead of the *Alesia*, also arrived on the 23d. She was carefully examined, but no signs of cholera were found on board, and she was allowed to proceed to the city after being fumigated.

Later reports show that two more of the passengers, held in quarantine on Hoffman Island, died on the evening of the 24th, and one expired at five A.M., on the 25th, at which time it was reported that twenty-three of the passengers are very ill, and one is likely to die. The others are improving.

Those who contemplate a foreign tour this winter may find it of interest to remember that numerous cases of cholera have occurred for the last five or six weeks in the towns about Rome, notably Tivoli, as well as in other parts of Italy and Sicily.

MEDICAL NOTES.

— Dr. Férand, chief of a large Marine Hospital in France, considers tape-worm fifty times as frequent in the Marine Hospital patients of France as it was twenty-five years ago. Of 1,842 cases, he succeeded in obtaining the expulsion of the parasite, head and all, in only 425. He found little efficacy in turpentine, ether, pumpkin-seed, and male fern. Kousso is useful, if perfectly fresh, but it rapidly deteriorates. The rind of pomegranate root is the best cænicide, and pelletierine the best preparation. He gives, the patient being kept in bed, an infusion of senna at 6 A. M.; at 7 A. M., seven grains of tannate of pelletierine, dissolved in simple syrup. This is repeated in one-half an hour. At 8 o'clock, an ounce of castor oil. The patient to keep perfectly still, to avoid nausea.

BOSTON.

— Dr. Martin, the eminent gynæcologist of Berlin, who has been in attendance at the International Medical Congress in Washington, and at the meeting of the American Gynæcological Society in New York, was entertained at breakfast at the Brunswick, last week.

NEW YORK.

— Dr. Henri Nachtel, of Paris, whose efforts, eight years ago, resulted in the establishment in New York of a night medical service, by means of which any one can secure the prompt attendance of a physician at all hours of the night by calling upon the nearest police officer, is now in the city for the purpose of securing $10,000, in addition to $10,000 that he has already raised at home, to enable him to start an ambulance service in Paris similar to that now in use in all the larger cities of the United States. As long ago as 1880, Dr. Nachtel read a paper on the American ambulance system before the French Academy of Medicine, and, a committee of leading physicians having reported in favor of the project, an appeal was made from the Academy to the Minister of the Interior, asking that the system be established in Paris as soon as possible. For several years, however, the public authorities refused to take any active measures to organize an ambulance service, on account of the expense involved, and Dr. Nachtel then resolved to try to gain his end by private means. Accordingly, he started a society, composed of such men as Jules Simon, the former Prime Minister, who became its President, Alexander Dumas, General Boulanger, Louis Pasteur, the Duc de Broglie, Arsène Houssaye, Ernest Renan, Léon Say, and Albert Wolff, and during the last two years he has succeeded in raising $10,000. He desires the money now to be subscribed to pass through the hands of a committee of prominent American citizens to the French committee in Paris, and states that if the additional $10,000 can be secured in six weeks, he will have the American ambulance system at work in the most populous quarter of Paris before the end of the year. He has no doubt that it will demonstrate its superiority to any other method so quickly, that the authorities will very soon provide the 1,000,000 or more francs necessary to extend the system over the entire city.

— The Board of Health has appointed Drs. E. G. Janeway, A. Jacobi, C. R. Agnew, J. D. O'Dwyer, Stephen Smith, George F. Shrady, and D. M. Stimson, a Board of Consulting Physicians and Surgeons for the Willard Parker and other hospitals of the department. Drs. T. M. Prudden and H. M. Biggs have been appointed pathologists to the department. Dr. James B. Taylor, who, for many years, has been at the head of the vaccinating service, has resigned his position as Chief of the Vaccinating and Contagious Diseases Bureau of the Board of Health.

— Early on the morning of September 20th, Dr. Theodore Hornblower and his wife, of Jersey City, had a desperate conflict with burglars who had entered

their residence. Several shots were exchanged, and the Doctor was slightly wounded in the neck. The burglars succeeded in making good their escape, but one of them was apparently severely wounded, by the trail of blood which he left. On the same afternoon, a man applied to a Harlem druggist for assistance, on account of a bullet-wound of the thigh. He was sent to the Harlem Hospital, and the police notified; and he has now been identified by both Dr. and Mrs. Hornblower as the man who entered their room.

— Small-pox has broken out on Staten Island, and of four cases reported at Stapleton and Port Richmond, within forty-eight hours, two have proved fatal. The Board of Health of Edgewater has ordered the district school at Middletown to be closed, as this school-house is situated directly in the rear of the building where the disease originated.

Correspondence.

NINTH INTERNATIONAL MEDICAL CONGRESS, GYNÆCOLOGICAL SECTION.

BOSTON, September 21, 1887.

MR. EDITOR,— Permit me to correct an error in your review of the work done in Section V. of the late International Medical Congress. You give credit to the Section work, but state a part of the interest was due to papers which should have been read in the Obstetrical Section.

This is the first time obstetrics and gynæcology have been separated, and it was natural papers should be referred by authors to either Section which would have been more appropriate to the other. Dr. Miller and myself arranged our programme to our mutual satisfaction, only seeking the best interests of the Sections over which we had supervision.

A glance at the programmes will show that the chief difficulty under which we each labored, was the number of papers contributed — quite sufficient to have profitably engaged the Sections for another week.

Your correspondent, who found nothing to meet his approval, characterizes the papers before the Congress, "as a big wad of documents, which ambitious young men of inexperience combined with respectable practitioners to accumulate."

Of over sixty papers contributed to the Section of Gynæcology, *twenty-five* were by the distinguished gentlemen from abroad, attracted, as he thinks, to the Congress by a meeting of a Society which convened in another city a week later.

Were it worth the while, it would be easy to review in detail the criticisms of your correspondents, but fortunately too many of your readers were in attendance upon the Congress to be misled by such statements.

Permit me the honor of remaining, very respectfully,

HENRY O. MARCY, M.D.,
President of the Section of Gynæcology.

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 17, 1887.

Deaths reported 2,404: under five years of age 1,056; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 595, consumption 281, lung diseases 169, diarrhœal diseases 276, diphtheria and croup 122, typhoid fever 30, malarial fevers 41, whooping-cough 27, scarlet fever 23, cerebro-spinal meningitis seven, small-pox three, measles three, erysipelas one, puerperal fever one. From malarial fevers, New Orleans 11, Baltimore 10, New York seven, Brooklyn five, Charleston four, Nashville three, Philadelphia one. From whooping-cough, New York nine, Boston seven, Baltimore four, Philadelphia three, Milwaukee two, Brooklyn and Pittsburgh one each. From scarlet fever, New York seven, Brooklyn and Boston four each, Philadelphia and Milwaukee two each, Pittsburgh, Cambridge, Fall River and New Bedford one each. From cerebro-spinal meningitis, New York and Worcester two each, Lowell, Holyoke, and Taunton, one each. From small-pox, New York three. From measles, New York, District of Columbia and Charleston one each. From erysipelas, Pittsburgh one. From puerperal fever, Brooklyn one.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,089, for the week ending September 3d, the death-rate was 18.9. Deaths reported 3,348: infants under one year of age 1,117; acute diseases of the respiratory organs (London) 169: diarrhœa 500, scarlet fever 84, whooping-cough 76, measles 49, fever 47, diphtheria 31, small-pox (Sheffield) five.

The death-rates ranged from 13.3 in Huddersfield to 29.1 in Preston; Birkenhead 21.4; Birmingham 18.3; Hull 18.3; Leeds 19.2; Leicester 25.0; Liverpool 20.4; London 16.6; Manchester 25.0; Nottingham 17.9; Sheffield 18.5; Sunderland 22.1.

In Edinburgh 17.6; Glasgow 19.2; Dublin 37.5.

The meteorological record for the week ending September 17, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 17, 1887, TO SEPTEMBER 23, 1887.

CABELL, JULIAN M., first lieutenant and assistant surgeon. Relieved from duty in connection with the Annual Department Rifle Competition at Bellevue Rifle Range, Neb., ordered from duty as medical officer at the "Rifle Camp for Team of Distinguished Marksmen," Bellevue Rifle Range. S. O. 89, Department of Platte, September 10, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING SEPTEMBER 24, 1887.

HARVEY, H. P., surgeon. Ordered to the United States Steamship "Mohican."

COOKE, G. A., surgeon. Detached from the "Mohican" and ordered home.

CLEBORNE, C. J., medical inspector. Promoted to medical director, September 18, 1887.

WALTON, T. C., surgeon. Promoted to medical inspector, September 18, 1887.

BOYD, J. C., passed assistant surgeon. Promoted to surgeon September 18, 1887.

TRYON, J. R., surgeon. Ordered to Marine Rendezvous, New York, October 1, 1887.

FIELD, J. G., assistant surgeon. Detached from Marine Rendezvous, New York, and ordered to the "Vermont."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING SEPTEMBER 24, 1887.

HUTTON, W. H. H., surgeon. Granted leave of absence for thirty days, September 15, 1887.

PURVIANCE, GEORGE, surgeon. Granted leave of absence for thirty days, September 13, 1887.

ARMSTRONG, S. T., passed assistant surgeon. Granted leave of absence for thirty days, September 13, 1887.

GLENNAN, A. H., passed assistant surgeon. To proceed to Charleston, S. C., for temporary duty, September 15, 1887.

WHITE, J. A., assistant surgeon. Granted leave of absence for twenty-seven days, September 13, 1887.

NORMAN, SEATON, assistant surgeon. Granted leave of absence for twenty days, September 16, 1887.

HEATH, F. C., assistant surgeon. To proceed to Mobile, Ala., for temporary duty, September 15, 1887.

WHITE, J. H., passed assistant surgeon. Promoted and appointed passed assistant surgeon from October 1, 1887. September 19, 1887.

PETTUS, W. J., assistant surgeon. To proceed to Savannah, Ga., for temporary duty, September 20, 1887.

GOODWIN, H. T., assistant surgeon. Appointed an assistant surgeon, September 22, 1887. Assigned to temporary duty at Norfolk, Va., September 23, 1887.

THE EXPERIMENTAL VALUE OF THE DOWSE SPLINT.[1]

BY E. G. BRACKETT, M.D.

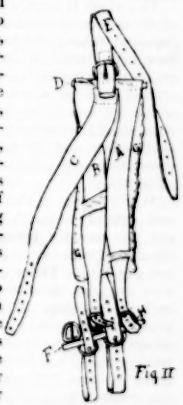

Fig I.

THE value of extension by apparatus in the active stage of hip-disease is well recognized, but mechanical aid in the convalescent period has received far less attention, and its value is less appreciated, especially the splint devised by Taylor, of New York, and called by him the Dowse splint. The object of this splint was to allow the leg the motion of walking, at the same time removing the pressure from the hip-joint. It is described in his "Mechanical Treatment of Diseases of the Hip-joint," in which he says: "A strong, upright bar of steel is jointed at the knee (Fig. I, A) in such a manner, that, when vertical, the rivet of the joint is behind the vertical line. It is evident that, with such a joint, vertical weight would not only be sustained, but would add firmness to the supporting power."[2]

The lower end is connected by means of a socket-joint (B), with a plate which is secured to the sole of the boot. At the upper, are the anterior and posterior arms for the attachment of the perineal bands, and in no way differ from the more commonly used Taylor splint. Greater strength is given by a smaller steel bar (C), parallel to the outer side of the original upright, being made a part of the joint at the knee, and extending some distance above and below, serving as a kind of buttress. The leg is kept in proper relative position to the splint by steel plates, which, in the original one, encircled both the thigh and calf, but these are now replaced, in part, at least, by simpler and less cumbersome means. The splint is so applied that the heel is raised from the ground a distance of from one to two inches, as desired, the toes being allowed to rest on the ground only after considerable flexion of the foot — a position decidedly at a disadvantage for any use. As the foot is brought to the ground, the weight of the body, resting on the perineal band, is sustained by the splint, which prevents the foot from receiving pressure. The leg serves to bring the brace into the different positions at the proper time.

When the perineal band is used to support the entire weight of the body, the parts are subjected to so much pressure, and especially, of course, with heavy subjects, that the ordinary round pad is frequently a source of continual discomfort, from concentration of so much pressure over so small an area. The same is true with less pressure, but unusually tender skin. For use in these cases, I devised a perineal band, the plan of which was to utilize all bony surface possible for support, and since it has now been used with comfort for nearly three years by a number of persons who were unable to bear the round pad, I think it has proved a usefulness.

The parts available for support are the tuberosity and ramus of the ischium, and a portion of the ramus of the pubis. The tuberosity is, of course, both in position and structure, best calculated for this work, but the ramus is also capable of considerable use. The object of the pad was to get a bearing surface as large as these bony structures would allow, and with a means to adapt this pressure as uniformly as possible to this uneven portion of the pelvis, and to change the amount in different portions of the pad. To accomplish this, three straps (A, B, C, Fig. II) pass beneath the perineum, and are firmly secured, posteriorly, to a steel bar (D), and anteriorly, to three buckles, thus allowing their length to be changed. The posterior bar is connected by a strap (E) at its centre to the posterior arm of the brace, thus allowing either end a certain amount of vertical oscillation. The three buckles are fastened to a similar bar (F), which has two straps to connect it with the anterior arm, little or no motion being allowed. Between these straps and the perineum is a piece of leather (G), its size regulating that of the pad, which is fastened to the bar behind. This serves to transmit the pressure of the straps, and also to keep them in position, which is accomplished by button-hole slits, through which the straps pass. The position of the straps is as follows: The outer one (A) passes along the outer border, and is secured to the outer buckle (H). It should pass beneath the tuberosity of the ischium. The second, or middle one posteriorly (B), crosses obliquely inward to the inner buckle, and by this, more nearly corresponds to the direction of the ramus to which it gives its support. The third, or inner (C), crosses the one just described, and is secured to the middle buckle, and gives its special support in the space formed by the divergence of the first and second. By this crossing, the inner edge of the pad is made concave, giving better adaptation to the parts. By this arrangement with buckles, the surface can be made to fit closely all the parts serving for support. Felting one-eighth of an inch in thickness may be used to cover the leather. More than this should not be used, as it interferes with the principle of the pad.

Fig II

In order to determine points of guidance in applying the pad, that it should occupy this relative position to the bony parts, I took measurements of different pelves, with the following result: The rami diverge in a horizontal plane, at an angle which, in the average of

[1] Read before the Surgical Section of the Suffolk District Medical Society, May 3, 1887.
[2] Loc. cit., p. 54.

those measured, was fifty-one and one-half degrees, and this line of direction, carried backward and upward on the dorsal surface of the ilium to the level of the anterior superior spine is, at this point in the female, two-thirds, and in the male, a little more, the distance from the anterior superior spine to the middle of the sacrum. Therefore, a line drawn from this point to the symphysis pubis would pass over the tuberosity and ramus. That the pad should have perfect apposition to this surface, it must pass over this obliquely, and it must be so applied, that posteriorly, its outer border shall be within this line of direction, and anteriorly, the inner border shall be on the outer side. In this position, the straps will come beneath the respective parts, as described.

The time for which Taylor intended the use of the splint was "after all pain and sensitiveness in the joint have ceased, and when there is no longer a disposition of the muscles to take on abnormal contraction, and there is free motion in the joint," for, he says, "the motions of the joint may be kept up with only good, and no harm, so long as pressure is removed, till the joint is completely well." [1]

This stage is certainly a trying one. In the absence of the inflammatory condition, the patient no longer is impelled to keep the joint at rest, and there is yet to be a long period of time occupied in repair, during which the articular surfaces are not capable of withstanding the effect consequent on a return of the use of the leg, and an important problem which now presents itself is: how can the patient be given the greatest freedom, and, at the same time, the joint be protected from any influence which may retard the process of repair.

While motion at this time is, of itself, not injurious, and certainly of much value to the long disused muscles, the recently inflamed structures are in no way capable of withstanding the combined effect of motion and pressure. Therefore, we must, in some way, prevent the joint from receiving the pressure incident in ordinary walking. Crutches and a high shoe remove pressure and protect the joint from injury, provided no accidental one comes to the leg while allowed to freely swing; but there are many cases, especially in older subjects, with whom there is urgent demand for the release from all possible restraint during this period of repair. If motion alone is not harmful, then any means which permits the leg the freedom in the movements of walking, but, at the same time, relieves it of pressure, will allow the joint the condition necessary for its repair, while the convenience to the patient is of the greatest; and if the Dowse splint accomplishes this, its theoretical use is correct.

Of the value of any appliance, we have two kinds of evidence, clinical and experimental. Of clinical, experience has proved this splint to be a valuable means of treatment in this stage of the disease, and in illustration, I will briefly allude to a few cases in which this splint has been used, and for the opportunity of presenting two of these, I would acknowledge my indebtedness to Dr. E. H. Bradford.

As it is not my object to report the cases, but only to use them to exemplify this treatment, I shall not resort to details of the history, but state conditions.

Case I. Girl, six years of age. Three years ago was seen early in the acute stage of hip-disease, and at once given a Taylor hip-splint and crutches, with extension at night. When signs of inflammation had disappeared, the splint was connected with the shoe, in the same manner as is the Dowse, but no motion at the knee was given. By this difference doubtless the pressure on the toe is less than when motion at the knee is given. She has worn this about two years, and her improvement has been steady. There is now no difference in appearance of the two limbs; there is free motion in about 40°, and without the splint there is a scarcely perceptible limp.

Case II. Girl, fifteen years of age. When seven, came under treatment for acute hip-disease, and after rest in bed for two months, was given a Taylor hip-splint and crutches, which were used for two years. At this time there was free motion in about 35°, and there was no pain or tenderness. Pressure gave no pain, but the leg was able to give but little support when the attempt was made to walk. The Dowse was given, and with this she was able to walk. For three months she kept under observation and continued to do well, but was then not seen for fifteen months. At this time she was in excellent health. The two limbs were nearly equal in size and strength, the amount of shortening was the same as when measured for the Dowse. It was found that after wearing the splint for a year, she gradually gave up its use, and has since walked without mechanical aid.

Case III. Male, twenty-six. At the age of fifteen there was disease about the hip, with abscess formation. When twenty-three he considered himself well, and was doing hard physical work under which, periarticular disease appeared, but involved the joint enough to cause the usual symptoms of disease of the head of the bone, as pain, muscular spasm, inability to use the leg. The sinus re-opened and discharged for a while. Under rest, these symptoms subsided, and he was then put on the Dowse, and with the aid of a cane was able to go about with ease. He has now used this for a year, and the improvement in the condition of the limb has been constant and satisfactory.

Case IV. Male, twenty-seven. Nearly six years ago had acute articular disease. After some months in bed, a Taylor splint and crutches were used for two years. After this treatment there were no longer signs of inflammation: there was free motion in about 30°. Pressure gave no pain, but it was only with considerable effort that the leg could be used to support the body. A Dowse splint was given, and has been worn from that time. There has been no interruption in the improvement of the limb, until at present it offers no restriction to the work which ordinarily would come to any one.

Although we have evidence of the clinical value of this apparatus, yet that it accomplishes the work which is claimed, has been doubted by some. In order to have an experimental estimate as well as clinical, of its value, I have endeavored to ascertain the actual work accomplished by it, and I am indebted to Dr. Bowditch, of the Medical School, for the opportunity of attempting these experiments, and also for his advice in the work.

As the Dowse splint is applicable only to those cases in which, as far as possible, the motions of natural locomotion are to be allowed, protecting the joint from pressure while admitting motion, its application must be to the mechanism of walking, and its adaptation such as to protect the joint, in the direction, and at

[1] Loc. cit., p. 53.

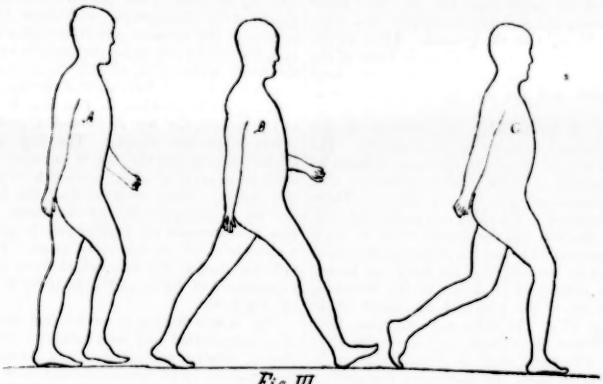

Fig. III.

the time of greatest shock and strain. Therefore the different motions of the step must be separated, in order to determine the time and direction of force from which by the apparatus we protect the joint. The division of the step into the different positions, is now accurately accomplished by instantaneous photography, and in the study of these I have used the series taken by Mr. Eadweard Muybridge, in 1881, and from which the figures in Plate III, are copied, by permission. Only such as have relation to the subject will be considered.

The chief element in the progression is the successively falling forward of the body, swinging on the ankle as a pivot, in each step being raised to allow it to fall again, or as Holmes has expressed it, "a perpetual falling, with a perpetual self-recovery." Therefore the body describes a series of regular curves, which correspond to the vertical oscillation, the amount of which is influenced by the length of the step. The body reaches its highest point in this vertical curve, at a time when it has just passed a point directly over the supporting foot. From this time it falls forward, until arrested by the foot which has been placed in advance and as the body passes on over this, it is raised by muscular effort to the summit of its curve. It is evident that the force exerted by the leg is by no means a uniformly distributed one, and it is the relative amount of strain, and the position in different parts of the step, that we have to study in dealing with this subject. When the body is in the summit of its vertical curve, the supporting, or active leg, is straight, (Fig. III, A), the other, or passive leg, is taking advantage of this moment of greatest altitude of the pelvis, to swing forward, with the knee flexed, to its position in advance. This leg remains flexed until the thigh is at that angle with the trunk, in which it is to receive the weight of the body. The foot continues to swing forward, until the leg becomes straight, and in this position the leg is held until it is brought to the ground by the falling forward of the body. (Fig. III, B). In this way the heel is the first to strike and receive the greater part of the shock, which comes to the foot at this time. The toe is soon brought to bear its share of the pressure in a time equal to a little more than one-sixth of the whole impact. Should the leg remain thus extended, this position would represent the body in the lowest point in its vertical oscillation, and its entrance on the ascending portion of the next curve, would be sudden, changing its direction at an angle. But at this moment the knee is slightly flexed, and by the shortening of this support, allows a continuation of the downward motion; thus its gradual checking, and the lowest point in the vertical oscillation is after the moment the heel strikes the ground. This position at this moment is represented in Fig. III, C. The foot which is about to leave the ground rests on the toe, while the supporting foot is flat on the ground, the leg bent at the knee. Carlet found this lowest point to occur at the middle period of double impact.[4]

As the body passes onward, it is raised to the summit of its curve by the straightening of the leg, which is complete at the moment the body has passed a point above the foot. (Fig. III, A). The other foot has now left the ground, and is swinging forward to take its place in advance. The manner in which it leaves the ground is as follows: As the body passes onward, the heel is raised, at the same time the knee flexed, allowing the toes to rest alone, (Fig. III, B and C), until the distance becomes greater than the length of the leg, when it is raised from the ground, and with the knee flexed swings forward. The body is now ready to again fall forward, and the process is repeated. Thus we can divide a step, for our subject, into three phases:

First, would extend from the highest point in the vertical oscillation, to the moment the heel strikes the ground, or the period of descent; Second, from the time the heel strikes the ground, until the lowest point in the vertical oscillation is reached, or the period occupied in checking the downward motion; and Third, from this last, to the time when the body reaches the highest point in the vertical oscillation, or the period of ascent. It must appear that the pressure is far from uniformly distributed over the two parts of the foot.

As the foot first strikes the ground, the centre of

[4] Annales des Sciences Naturales, xvi, vi, 34.

gravity is behind the ankle-joint, and the heel alone receives the shock, and sustains all weight for a time, when the toe is brought to the ground. Then, as the body passes to a point over, and then in front of the foot, the heel bears less, and the toe more, until the heel is raised, and the toe, for a moment, rests alone.

With a view of determining the estimate of this pressure, I performed a series of experiments. The apparatus used was, in principle, the same as used by Carlet, and consisted of thick rubber cylinders, with air-chambers connected with Marey drums. These rubbers were fastened to the shoe, one under the heel, and one under the toe, and the drums were so regulated that the amount of excursion of the needle which would be caused by the weight of the body was known in each. This difference is shown in the following tracings, which are of the heel and toe, taken in the same step (Fig. IV). As these are examples from the walk of different individuals, they naturally show some points of difference, such as characterize an individual gait, but all show the distinctive features for which they were taken. The amount of pressure is indicated by the elevation of the curve, while the dotted line represents the height which corresponds to the weight of the body. As is seen, the heel receives alone all the pressure which comes suddenly to the foot, and that it is only after a well-marked interval that the toe takes an active part. As the centre of gravity of the body passes in front of the ankle-joint, the pressure is gradually transferred to the toe, and for a moment, at the close of the impact, all pressure is sustained by this part of the foot.

Fig. IV.

There are two parts of each impact, where, theoretically, more pressure comes to the foot, that which represents the weight of the body. In the second phase, when the descent of the body is checked, there must be used the additional force necessary to check a weight equal to that of the body falling a distance of the vertical oscillation, which is, according to Carlet, about fourteen millimeters in an average step.[8] Also in the third phase, when the body is raised to the highest point, there will be this corresponding additional force required. Carlet considered this additional force represented a weight not to exceed one-fifth that of the body.[9]

In combining the two parts of these tracings to represent the total pressure on the foot, I obtained a curve in the first part of the impact, above the line of body's weight, indicating an additional amount at this time. In the latter portion, the tracing remains at, or very near, the level of the dotted line, showing that at this time, when the body is falling forward, the force used is only that necessary to keep the body at a fixed distance from its pivot. Therefore, there is nothing in the pressure-curves of ordinary walking indicating the push of the toe so often mentioned. A glance at the photographs will show that such force applied at this moment would not give a forward motion, but would only raise the body in a nearly vertical direction, while it is, at this time, scarcely at the lowest point in the downward direction.

In regard to position, we find that in the beginning of the impact, the leg is extended, and the heel receives alone the shock. The leg is immediately slightly flexed, and the toe is brought to the ground after an interval of about one-sixth of the time of entire impact. Then, with the foot flat on the ground, the leg is straightened, and the body raised. As it now falls forward, the heel leaves the ground, and, for a short interval, the toe rests alone. It is an important fact that, at this moment, there is no call for extra expenditure of force, and also, there is no motion in the hip-joint.

But, in substituting a mechanical means as a part of so complicated and well-balanced a mechanism as that of walking, necessarily there results a change in the detail of its performance, and such does occur in walking with the aid of the Dowse splint. In ordinary walking, all pressure sustained by the ankle-joint is distributed to the foot, influenced by the relative position of the body and the time of impact. As both parts of the shoe are securely connected with the upright portion of the splint, so it is the object that the pressure on the shoe should be transmitted to the splint, and the foot prevented from taking part in this by its elevation. The splint should not only receive the weight of the body in the beginning of impact, but retain it until the foot is about to leave the ground. To accomplish this, the splint must be held straight during this time, and as this occurs at that time when, in natural walking, the knee is flexed and then extended, a change from ordinary walking must take place. To prove the occurrence of this change from the normal walking, I photographed, while in motion, an adult wearing a Dowse. The positions in this part of the step may be seen in the accompanying photographs. As the foot swings forward, the splint becomes straight, as does the leg in natural walking, and in this position, receives the weight of the body (Fig. V, A), but at this moment does not bend, as does the knee, as has been described, but remains straight, supporting securely the weight of the body. Therefore, the body, instead of reaching the highest point in its next vertical oscillation by a direct lift, must swing upward through an arc of the circle, which has the splint for its radius. The positions during this movement are seen in Fig. V, B and C.

A jar to the body from this sudden change in direction is prevented by the elasticity of the brace. Passing this point, the body now falls forward, held by the splint, until, just before the termination of the impact, when the heel is raised, and the splint can no longer receive all pressure, as before.

Thus the foot is protected from pressure, except in the last moment, when it is in the act of leaving the ground, and this at a time when the least is required.

Since the toe is allowed a position in which it may momentarily bear pressure, necessarily the opportunity is taken, and a certain amount is sustained by this part of the foot. To determine this, I took a series of tracings in the same manner as with natural walking (Fig. VI). In these, the lower curve represents the

[8] Animal Mechanism, Marey, p. 118.
[9] Loc. cit., p. 25.

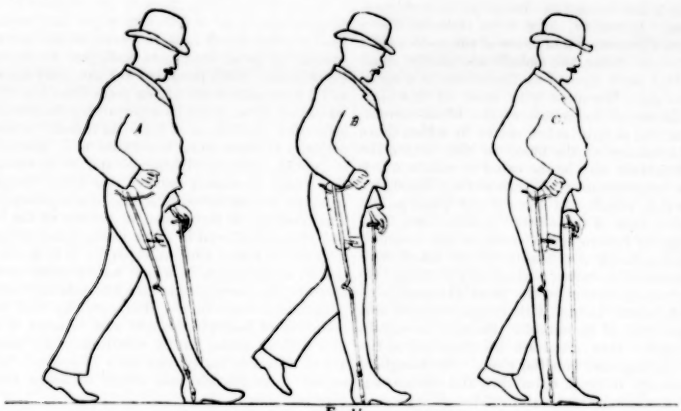

Fig V

pressure sustained by the splint, the upper, that by the toe. It is seen that the brace receives the weight alone for the greater part of the step, and in that part of most strain, while that of the toe is but of short duration, is gradually imposed, and, in amount, is never great.

Fig VI

Therefore, of its work I think we can say that, in the first portions of the impact, it protects the leg from pressure, and this at a time when greatest strain is usually sustained by the leg. That slight pressure is allowed the toe for a moment at the close of the impact, but this comes at a time when motion is not occurring in the hip-joint. Knowing the actual protective value, in addition to the clinical evidence of its usefulness, we need no further explanation for its application, except the conditions under which we wish the joint to be while in its treatment. It must appear that, in the proper cases, it is a valuable means of treatment. Certainly, there is a time in the convalescence when the joint can bear this amount of pressure, as has been described; yet the weight during the whole step, and especially in the first of the impact, when there is considerable shock to the joint, could in no way be allowed with impunity. This being removed, but little actual work is left for the leg to do. However, more intelligent care on the part of the patient than with ordinary apparatus is necessary, for the opportunity is present to make more use of the limb than is intended. Unless the splint is straight, as has been described, it does not bear the entire weight.

There is no reason why its use should be restricted to hip-disease, but it may be employed in any case where the leg is to be relieved of its work, or a portion of its work; and Taylor recommended it for permanent use after exsection of the head of the femur, and in ununited fracture of the neck of the femur, there is certainly opportunity for experiment.

NOTES ON HÆMORRHAGIC INFARCTION.[1]

BY WILLIAM OSLER, M.D., OF PHILADELPHIA.

Regarded as an incident in the course of various affections, hæmorrhagic infarction has no special status as a morbid entity, and can scarcely be considered apart from those conditions which render its occurrence possible; namely, a certain anatomical arrangement of the arteries, with obstruction of a terminal branch by an embolus or a thrombus. Into anatomical details I do not propose to enter, but shall confine my remarks, first, to the conditions in which we meet with infarction; and, second, to special features of the process in certain organs.

In looking over the notes of a number of cases in which infarctions occurred, I find they may be grouped into three sets: First, cases with fresh endocarditis, and lesions unquestionably embolic; second, cases in which there was thrombosis in regions other than the affected vessel; third, cases in which, so far as could be ascertained, the infarction resulted from the formation of a primary thrombus in the affected vessel, or was part of a condition of multiple thrombosis.

Upon the first group of cases I shall not dwell, further than to note that conditions of the endocardium, apparently the most favorable, may exist without the occurrence of infarcts. In several instances of severe ulcerative endocarditis, there was a notable absence of multiple emboli, while in others the distribution has been peculiar; for instance, to the brain alone, none to the abdominal viscera, or to the intestine chiefly. I have, also, the records of twenty cases with numerous endocardial vegetations, in which there were no infarcts.

In the second group, the infarctions resulted from the dislocation and transferrence of fragments of

[1] Read before the Association of American Physicians, June, 1887.

thrombi which had formed in various parts of the vascular system. In reality, there is no essential difference between these cases and those of the endocarditis group, as, in the latter, the emboli are chiefly small thrombi, which have formed on the valves as a result of inflammation. We meet with cases of this class under conditions of feebleness of the blood-current, and in septic and certain other states in which there is a special tendency of the blood to clot within the vessels. Whatever may be the cause or causes which prevent the coagulation of the circulating blood, we must admit that rapidity of the current plays an important part. Loss of the normal endothelium, upon which Cohnheim lays so much stress, as the essential factor in maintaining the fidelity of the blood, may exist to a remarkable extent without any clotting. Instances are not uncommon of the most extreme calcification of the aortic intima with rough, exposed surfaces, and no trace of thrombosis. So, also, in certain aneurismal sacs. How often are we surprised at the absence of the expected lamellar clots. Recklinghausen has specially insisted upon this, and claims that slowness of the blood-stream, and sudden dilatation in its course, are much more important elements in the production of marasbus thrombi than loss of integrity of the vessel wall. The recent observations upon the formation of thrombi touch this question in an interesting manner, and bear directly upon it. Evidence has been gradually accumulating to show that the blood-plaques play a leading *rôle* in the early stages of thrombus-formation. My observations on this subject would lead me to conclude (1) that certain of the marasmatic thrombi so common in the iliac, femoral, and pelvic veins are composed, in great part, of blood-plaques; (2) the globular thrombi of the heart-cavities are largely made up of the same elements; (3) that they play an important part in the formation of the laminated coagula of aneurismal sacs; (4) the soft thrombi which form on atheromatous patches of the aorta are, to a great extent, aggregations of blood-plaques. To these facts, we may add the experimental demonstration which I, as well as others, have offered, that in a lacerated vessel, these bodies are the very first elements to adhere to the torn tissue, and form the basis of the thrombus.

One among many of the interesting points determined by Eberth and Schimmelbusch, in their investigations on the subject, is the relation of the plaques to the blood-stream. When rapid, they keep a central position with the red corpuscles; but when, from any cause, the current slackens, they accumulate in the peripheral still layer, and tend to adhere to the intima. When the velocity of the flow is maintained, there may be a lesion of considerable extent without any attempt at clotting; but if the stream slackens, the first effect is the agglutination of the blood-plaques on the torn surface, and the formation of a white thrombus.

Now, the connection of this with the subject in hand lies in the fact that we most commonly meet with thrombi in conditions of general or local feebleness of the circulation. The infarcts occurring in this group of cases are, as a rule, easily traced to their source: those of the lungs to the globular thrombi of the right chambers, or clots in the systemic veins; those of the brain, abdominal viscera, and extremities to the thrombi in the left chambers, in aneurisms, or on atheromatous surfaces.

In the third group, we find the infarction and the plugged vessel, or we find multiple infarcts, and the most careful search fails to reveal either the primary source, or local conditions sufficient to account for thrombosis. Such instances are not very uncommon, and I have picked out fifteen cases from my records in which, so far as could be ascertained, the hæmorrhagic infarction was due to a local thrombotic process. A majority of these were associated with specific fevers — typhus, typhoid, diphtheria, and septicæmia. One was a case of cholera morbus, one acute Bright's disease, and one occurred in a case of morphia-poisoning. The tendency to thrombosis in certain of the fevers is well recognized, and in these cases, some other factor than debility may come into play. It is worth noting that in septic states, in which we so often meet with thrombi, the blood-plaques are exceptionally abundant.

Here and there in the literature, we find recorded instances of multiple thrombi and infarcts in association with an acute febrile condition. As these cases are of extreme rarity, and very obscure, I will here report a remarkable case which occurred under my care last year:

John Mullen, aged twenty, laborer, admitted to Philadelphia Hospital, October 10, 1886. He was a well-built, healthy-looking man. Never had had syphilis. Had been a hard drinker at times. Two years ago, in Pittsburgh, had typhoid fever: ill for six weeks. Present illness began, about a week before admission, with diarrhœa, and he felt constantly weak, exhausted, and had no appetite. For two days he had nose-bleeding. When first seen, on 11th, pulse 112, temperature 102⅘°, respiration 20; was rational. Expression of face dull. Complained of pain in abdomen, which was slightly swollen, and, on palpation, painful in left hypochondriac region. Beneath skin of anterior thoracic region and of abdomen, were many localized blue spots (tâches bleuâtres). Heart-sounds muffled; no murmur. Examination of lungs negative. Urine clear, no casts, trace of albumen. Tongue coated, white. Splenic dulness increased; edge not palpable.

On the 12th and 13th, the temperature did not rise above 103⅘°; the abdominal pain increased; was most marked in splenic and inguinal regions. Delirium almost constant, though, at times, he could be roused to give an intelligent answer. Had had one or two loose stools; no diarrhœa. No characteristic eruption. The *blue spots* persisted. Tongue became dry. On the evening of 13th, the feet were noticed to be very cold, and he complained of it; and, on the 14th, the feet and legs, as high as the knees, were cold, slightly swollen, and of a mottled-red color; pulse 120, temperature 102°; great restlessness; persistent delirium; abdominal tenderness continued, particularly over spleen, the dulness of which extended to little below costal border. Heart feeble; no murmur. On the 15th and 16th, the legs became of a deep, livid-red color, as high as middle of thighs; no pulsation in femoral or popliteal vessels. Low delirium; tongue dry; pulse 120–140, temperature 101–103°. Blood examined, with negative result. Urine scanty, albuminous. He sank, and died on the morning of the 17th, a week after his admission, and about two weeks from the beginning of his illness.

The case was regarded as one of typhoid fever, the epistaxis, diarrhœa, and abdominal swelling and tenderness supporting the opinion, though a doubt always

existed, on account of the very positive statement of an attack two years before. The thrombosis in the iliacs and gangrene of the legs were looked upon as illustrations of a rare, but well-recognized, sequence of typhoid fever. The autopsy showed thrombosis of the lower two inches of the abdominal aorta, with plugging of iliacs and femorals, the clots firm, reddish-brown, and closely adherent. Mesenteric vessels free; two large branches of the splenic artery plugged. The spleen, three times the normal size, presented three or four infarcts; the upper one, as large as a small orange, was soft, covered externally with thick layers of lymph, and closely united to the stomach and colon. From this point, extended a general peritonitis. The right kidney presented two large, red-brown infarcts. The ileum was normal; no hæmorrhoids; bladder, prostate, and testicles normal. No endocarditis; lungs normal. Brain healthy; no otitis; no bone-lesions. During life, the blood was carefully examined for micro-organisms, but none were found. After death, in the infarct of the spleen, and in the lymph covering it, there were numerous micrococci.

Passing from a consideration of the conditions under which infarctions occur to special features of the process in certain organs, I will submit, first, an interesting, possibly a unique, instance of hæmorrhagic infarction of the liver. Under ordinary circumstances, this is impossible, for although the terminal branches of the portal vein have not extensive anastomoses with each other, occlusion is of no moment so long as the circulation is maintained in the hepatic artery. Indeed, as in a case which I reported,[1] there may be for years complete obliteration of the portal vein without interference to any apparent extent with the functions of the organ. The case is as follows:

A. B., aged sixty-two; an old soldier and a hard drinker. Illness began in June, when he had dropsical symptoms. In July he took a voyage from Newfoundland to Labrador, and came to Montreal, September 27th. He had been ill nearly all the way from the Gulf, and the dropsy had increased very much. When admitted to the General Hospital he had ascites, vomiting, and hæmatemesis. Death took place on the second day after admission.

Autopsy: Much fluid in peritoneum and in left pleura. Heart and lungs normal. Stomach contained a bloody fluid; mucous membrane stained, not eroded. Small intestine contained a quantity of altered blood. Liver was large; weighed 2,400 grammes; capsule a little opaque, and at right border was a little thickened. Organ extremely cirrhotic, the lobules mapped out in small irregular areas, not projecting much, but giving the characteristic granular appearance. A considerable portion of the right lobe presented a remarkable appearance, neither like a normal nor a cirrhotic organ. There were areas of red-brown and light-brown tissue, in places mottled, very dry, friable, and readily torn. Strands of connective tissue passed through these parts, but the cirrhotic character of these parts was lost. It resembled a firm infarct of the spleen. Microscopical examination showed these reddish areas to contain innumerable blood corpuscles, infiltrating the entire tissue. The liver-cells were small and fatty, in places indistinguishable. The portal vein presented a soft brown thrombus, occupying the upper part of the trunk, but not completely obliterating it; the branches passing to the right lobe had closely adhering light-brown thrombi; that passing to the antero-lateral region, where the infarct was situated, was filled with a firm, solid, partially laminated clot, evidently formed some time before death.

The condition of infarction is stated not to occur in the liver, owing to the fact of a double blood-supply, and if a branch of the vena portæ is plugged the capillaries of its territory receive blood through the hepatic artery, and *vice versâ*. In this case we may suppose that the interlobular connective tissue growth had obliterated a majority of the hepatic artery branches in the affected region, and had thus converted certain trunks of the vena portæ into terminal vessels, which, when plugged with a solid thrombi, induced a condition of infarction in the area supplied by them. With the exception of a case to which Recklinghausen refers, I do not know of any instance in the literature of infarction of the liver.

Hæmorrhagic infarction of the intestine is an interesting lesion which we meet with in two forms; the one, a local process in the mucosa, the other, a general condition involving a portion of the entire gut.

Small infarcts of the mucous membrane are by no means infrequent in ulcerative endocarditis; they vary in size from a pea to a half-dollar, and present a central necrotic area, a zone of intense hæmorrhagic infiltration and congestion, and a central plug in the nutrient artery. In one instance I was able to find the embolus and determine its identity with the mycotic vegetations on the aortic valves. The central necrotic area may slough and leave a distinct ulcer.

Infarction of an entire section of the bowel is not a very common event in man; indeed, considering the large size of the superior mesenteric artery, we may wonder that it does not occur more often. In the horse, on the other hand, it is an extremely frequent lesion resulting from the transferrence of portions of clot from the verminous aneurisms which are so common in the mesenteric arteries. The fatal colic of these animals is the result, in a great majority of the cases, of hæmorrhagic infarction of the intestine. I have been long familiar with the condition, and have sought carefully for instances in man. The following cases illustrate the similarity of the lesions to those produced experimentally, as related by Dr. Welch:

Case I. A woman, aged fifty-five, had suffered for a year or more with dyspeptic symptoms, and had vomited a small amount of blood, had lost flesh, but was not cachectic. No tumor of abdomen could be made out, but cancer of the stomach was suspected. The details of the last week of her illness are as follows: On April 14th, 15th, and 16th, she had nausea and vomiting: on the 17th she went to bed. There was vomiting and considerable epigastric pain; pulse about 90. On the 18th she was easier. 19th, much worse; she had fainted in the night; pulse weak, 115; face pale, feet cold, vomiting frequent. In the evening the temperature was 101°, pulse 120; the pain in abdomen was more diffuse, and there was considerable distension. On the 20th, condition did not improve, though, under opium, the distress was not so great. On the 21st, prostration more marked, and the next day the vomiting was distinctly fæcal and frequent. Death on the 23d.

At the autopsy, the small intestine, from an inch or two below the duodenum to within two inches of the valve, was dark in color, distended, and covered in

[1] Journal of Anatomy and Physiology, London, 1882.

places with a thin sheeting of lymph. Several spots in the ileum looked almost gangrenous, and here and there extravasations had taken place. The coats were infiltrated, the mucosa soft, and there were three spots (ulcers) from which the membrane had disappeared. There was no heart disease. In abdominal aorta a few flakes of atheroma. At the orifice of the superior mesenteric artery was a large button of atheroma which had ulcerated on the surface and to which was attached a firm thrombus, completely blocking the vessel for one-and-a-half inches from the aorta.

CASE II. A woman, aged about seventy-five, was admitted to hospital under Dr. Ross, with necrosis of the femur. She was seized four days afterward with severe abdominal pain and frequent vomiting; there was diarrhœa at first, and then symptoms which pointed rather to obstruction, persistent vomiting, and great distension of the belly.

At the autopsy the small intestine was found greatly distended and of a deep livid-red color; no inflammation of the peritoneum, but about one-and-one-half pints of bloody serum in the sac. The coats of the bowel were swollen and deeply infiltrated with blood and serum. For about a foot from the pylorus the appearance of the gut was normal, and the last six or seven inches of the ileum were also healthy. The mucosa was deeply congested, soft, and readily scraped off. The mesentery was congested and infiltrated. In the heart, the mitral valve presented numerous recent warty vegetations, soft, pedunculated, and easily torn. The aorta was moderately atheromatous. Dissection of the cœliac axis showed the splenic artery blocked by firm brownish thrombus, which extended from about an inch from the hilus into the branches of the second and third degree. The organ was small and had a turbid, reddish-brown appearance. The hepatic artery was occluded by a firm thrombus, which began near the bifurcation and extended into both branches. The superior mesenteric artery contained a firm brownish-yellow clot, which began about a quarter-of an inch from the aorta and extended an inch-and-a-half into the two main branches. Before this chief division six smaller vessels were given off, all of which were plugged. In tracing down the large branches, two of them contained firm thrombi about an inch from the bowel.

CASE III. J. C., aged forty, an engineer, large muscular man, patient of Dr. Gardner. Good health up to a year before death, when he began to suffer with pains in the back. While wheeling a barrow full of cinders, he was suddenly seized with intense pain in abdomen and groins, became faint, fell to the ground and vomited. He lived for a week after. The chief symptoms were persistent vomiting, which resisted all the usual remedies; severe diarrhœa; great pain in abdomen, which was distended. The voice was husky, eyes sunken, features pinched, and the whole appearance choleraic. The stools were thin, and at times blood-tinged. The temperature did not exceed 101°; pulse was small and infrequent, rarely over 90.

The autopsy revealed an abdominal aneurism, involving the aorta just at the diaphragm. The axis, superior mesenteric and renals were given off from the sac. There was a dissecting aneurism of the lower part of the abdominal aorta and the iliac. The blood had passed from the sac beneath the intima at the hinder part of the aorta, and on the right side, and had passed into the iliac, elevating the intima, and narrowing their calibre. On the right side of the external iliac it had burst externally by a tiny orifice, and a thin sheeting of blood extended beneath the pelvic peritoneum and in the lumbar region. The small intestine was swollen, and of a deep purple-red color; the walls infiltrated with blood and serum. The superior mesenteric artery arose from the most prominent part of the sac, and the orifice was dilated. About half-an-inch within the vessels was a firm plug of the fibrinous lining of the sac which had been dislodged and carried into the artery. There was a pretty firm coagulum about it, and, on the distal side a dark clot. The mesentery was thickened and infiltrated, and its veins full.

Regarding hæmorrhagic infarction of the lungs, I would refer briefly to the following points:

(1) The frequency with which we find vessels plugged without resulting infarction, even when the obstruction is total.

(2) The important part played by globular thrombi of the right auricular appendix in the production of infarcts, particularly in the last stages of valvular disease.

(3) The occasional occurrence of thrombotic infarction as a result of local disease of the pulmonary artery. We find this, as in the specimens I show, in atheroma of its branches in mitral stenosis, and in the endarteritis induced by the encroachment of tubercles in chronic phthisis.

(4) The occurrence of cases of pulmonary infarction in which a careful and thorough examination, such as is ordinarily possible to make in hospital work, fails to give any clew to the origin of the obstructing thrombi.

A CASE OF TUMOR OF THE BREAST.[1]

BY S. J. MIXTER, M.D.,
Assistant Demonstrator of Anatomy, Harvard Medical School. Surgeon to Out-Patients Mass. Gen. Hospital. Instructor in Surgery, Boston Polyclinic.

THE following case is reported, as it presents certain interesting features, and in order that attention may be drawn to methods of treatment and operation, not sufficiently insisted upon by many surgeons.

The patient, a young married woman, twenty-six years of age, was seen in consultation with Dr. Cook, of Natick, March 16th, and the following history obtained. She first noticed a lump in the breast six months ago. This was treated by an irregular practitioner by massage, without any material change in its size, for three-and-a-half or four months, when it began to grow rapidly. Since then, it has steadily increased in size until at the time of examination, it apparently involved the whole gland, the breast being enlarged, hard, and prominent, fairly movable, the nipple retracted, and the skin near the nipple fixed to the tumor. The axilla was filled with a hard movable mass.

After a consultation with Dr. D. W. Cheever, it was thought advisable to operate and endeavor to remove the mass as completely as possible. The rapid growth and extension of the disease to the axillary glands rendered the ultimate prognosis unfavorable, but it was hoped that a thorough operation might, at least, prolong life, and would give the patient the benefit of her only chance for recovery.

[1] Read before the Surgical Section of the Suffolk District Medical Society, May 3, 1887.

I operated at the patient's home on March 23d. The breast was removed, together with a large amount of skin and nearly the whole of the pectoralis major muscle, to which it was attached, and which, on its upper surface, was studded with an occasional small nodule. The axilla was thoroughly cleaned out, according to a method I first heard insisted upon by Dr. M. H. Richardson; namely, to first expose the axillary vessels and then to remove the contents of the axilla. The artery and vein were exposed from the lower edge of the latissimus dorsi to the lower border of the first rib, every branch of both artery and vein tied and cut, except the main trunk of the sub-scapular. No tissue of any kind remained in the axilla when the dissection was completed.

It was with great difficulty that the skin could be brought together, even by means of deep stitches placed three and four inches back from the edges of the flaps — dressed with iodoform gauze.

The wound healed throughout, except at the axilla, where there was a small "dead space;" that is, a space where the deep surfaces of the wound were not in apposition. Here a small clot formed and gave rise to a small abscess, which was relieved later by re-introducing a drainage-tube. Patient sat up in a week, and is practically recovered from the operation at the end of two weeks.

Dr. W. F. Whitney, who kindly examined the tumor, reports it to be a very cellular mammary cancer.

The interesting points in connection with this case are, the presence of a growth of this nature in so young a patient; and the question of the influence of massage on the growth and extension of the disease.

One can but think that the treatment of a malignant tumor by massage, could only result in its more rapid growth, and stimulate not only the cell-production but perhaps favor its progress along the lymphatic vessels to neighboring glands and tissues.

In speaking of this operation in general, I wish to lay special stress on the necessity of removing a large amount of surrounding tissue with the gland, making a thorough and systematic dissection of the axilla, in every case, whether the glands are enlarged or not, and leaving no tissue between the two through which run the lymphatic vessels. To do this, the fascia covering the pectoralis major and the part of the minor exposed, should be dissected off with the tumor. All the contents of the axilla should be removed except the axillary vessels, brachial plexus, and sub-scapular nerves. These last, which are given off from the posterior cord of the plexus, should always be saved, if possible, as Küster has shown in a late article, that the varying amount of disability in the use of the arm, seen after these nerves have been sacrificed, is avoided when they are left. They supply the sub-scapularis, teres major, and latissimus dorsi muscles, and can always be readily found during the dissection. If they are divided or removed, paralysis of these muscles follows, and, as a consequence of the paralysis, a growth of connective tissue takes place in the substance of the muscle, making it much less elastic than it normally is. The sub-scapular vessels may generally be saved.

The following are one or two practical points in regard to the incision, and the method of sewing up the wound. The mammary incision should be continued along the border of the pectoralis major; in other words above the upper boundary of the axilla, and the skin should then be dissected downward and backward. By doing this, the line of suture comes well forward in the axilla.

A quilted suture passed through the axillary skin at a point corresponding to the apex of the axilla, then through the serration of the serratus magnus on the second rib, and out again through the skin, about a quarter-of-an-inch from the point of entrance, the two ends being tied after all the other sutures are applied and just before dressing the wound, almost completely closes the "dead space" spoken of, and, by carrying the skin so high in the axilla, prevents union of the arm to the side. This I have done in a case operated upon since the one reported, with very satisfactory results. In previous cases I have generally had slight suppuration in this space. A second quilted suture can be passed through the axillary skin and pectoral muscles, and tied on the front of the chest, if the tension seems too great on the first stitch.

Drainage, to be successful, must be made by a tube through a buttonhole cut near the anterior border of the scapula.

I am aware that there is little or nothing new in these suggestions, but it has seemed to me that many surgeons do not appreciate their importance. The old practice of removing the breast alone, in malignant disease of that organ, leaving the axilla if no glands could be felt, and in case of enlargement removing the glands only, seems to me to be entirely opposed to the ideas of modern surgery. By this method almost no radical cures resulted, and many skilful and judicious surgeons came to look on the operation as almost useless, subjecting the patient to unnecessary suffering and anxiety, without a prospect of corresponding benefit.

Even with the greatest amount of care and thoroughness, many failures must follow operations for malignant disease, but the modern radical operation, when properly performed, shows results seldom or never arrived at by the old methods. Statistics of the results of operations in cancer of the breast, should to-day include only those cases where the operation has been thoroughly done. Patients to-day, have a right to expect such an operation, as giving them their best chance of life, and no surgeon should content himself with simply removing the mamma and then pointing with pride to a union by first intention, when already the disease has probably crept over the edge of the pectoralis muscle, and though not perceptible to touch, may be working its way along the lymphatics, out of reach of the knife. That is not surgery, it is simply an unscientific and incomplete operation.

REPORT ON PROGRESS IN THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M.D.

[The reporter is much indebted to WILLIAM H. POMEROY, M.D., of Springfield, for his assistance in preparing the report for this year.]

ANTIPYRETICS.

ANTIPYRETICS have recently been the subject of much practical and scientific study and observation; and as seemed probable with the first results of synthetic chemistry in this direction, each product has been better than its predecessors.

KAIRIN, THALLIN, HYDROCHINON.

It will be remembered that kairin, thallin, and hydrochinon, while effective in reducing temperature, had a peculiar action on the blood and circulation which rendered their use in excessive doses, somewhat unsafe. The experiments of Dr. Beyer [1] showed that kairin and thallin, and perhaps hydrochinon, had a destructive influence on the red corpuscles of the blood, accounting for the change of color caused by large doses. Kairin and hydrochinon have further a decidedly weakening effect on the heart: that is, are muscle poisons in large doses producing diastolic arrest. Thallin has the same action, but to a much less degree. These experiments explain the objections found to the clinical use of these drugs; and the many cases of collapse, cyanosis, and temporary heart failure observed, as also the manner of their action, sudden reduction, rapid succeeding rise of temperature with often rigors; these considerations placed their successor, antipyrin, far in advance in professional favor.

ANTIPYRIN.

The advantages of this agent as an apyretic are well evinced in the series of experiments to which already reference has been made. Unlike the preceding drugs it does not alter the constitution of the blood, and is not a muscle poison, while, however, it does depress the heart's action, probably its greatest defect. Its antipyretic action seems chiefly by increased local dissipation, by dilatation of surface capillaries. Clinically it was found safe and effective, in comparison with its predecessors, but later it was found to produce a depressing effect, decidedly objectionable in some cases and certain forms of disease, notably pneumonia and diphtheria. In general, a condition of weakness, with tendency to cyanosis, contraindicates its use. In the high temperature of beginning typhoid, and especially in acute articular rheumatism, it is found to give its best results. In typhoid, fifteen-grain doses are given to anticipate the evening rise: that is, fifteen grains at 11 A.M., repeated at 5 P.M., if the temperature continues to rise. This secures for the patient generally a comfortable night's rest, and is generally accompanied by free perspiration, and is advised when the temperature reaches or exceeds 103° F. No influence on the course of the disease is claimed, and its use in cases attended by great prostation and weak heart is open to objection.

Concerning its value in acute articular rheumatism, the inaugural essay of Dr. Eich [2] gives it high rank in this disease. Observations on thirty-six cases including acute and chronic articular rheumatism lead him to regard its anti-rheumatic action equal to that of salicylates.

Enjoining caution in the use of antipyrin, Dr. Geo. Dalton Heys [3] reports three very severe cases of collapse attributable to its use, due to too frequent repetition of doses in the endeavor to secure fall of temperature when the initial dose failed. His conclusions are: the drug, like many others, after repeated administration, may in the usual doses act less rapidly, and attendants should be cautioned not to push the remedy if it seems ineffective, but if the rise of temperature be considered dangerous, to send for the physician.

[1] Am. Jour. Med. Sciences, April, 1886, 369-403.
[2] Basel, 1886. Therap. Gaz., 1886, ii, 778.
[3] New York Med. Jour., January 22, 1887.

Karsh, of St. Petersburg, reports very unfavorably on antipyrin.[4] His cases were ten in number, three typhoids, three pneumonias, two of phthisis, one pleurisy, one acute articular rheumatism. He used fifteen-grain doses, three times a day, or oftener, even at hour intervals. Of the typhoids two died of complications (no inference), in the third the course of the disease seemed prolonged. In pneumonia and phthisis no good results are seen.

Dr. Enko [5] reports retardation of resolution in cases of pneumonia treated with antipyrin.

Dr. Posadski,[6] reports twenty-five cases of pneumonia treated with antipyrin and compared with twenty-three cases treated with calomel. He gave antipyrin in daily amounts of from fifteen grains to two drachms, calomel in the other series in one-eighth grain doses, four times daily. Conditions, ages, period of the disease, were as nearly the same as possible. The average duration of the disease in those treated by antipyrin was 8.1 days, in those treated by calomel 7.1 days, with antipyrin the termination was by lysis, with calomel, by crisis; with antipyrin there were five cases of collapse, four of vomiting, two of skin eruptions, eleven with dark cherry-colored urine, conditions none of which occurred in those treated by calomel.

The *Medical Record*, September 25, 1886, reports a case of sunstroke in which enormous doses of antipyrin failed to reduce temperature.

Antipyrin cannot, therefore, be regarded by any means a perfect antipyretic, and while undoubtedly a valuable drug in certain pyrexial conditions, yet has in it an element of risk in its depressing action on the heart, which greatly restricts its use and renders it ineligible in certain forms of disease with high temperature.

ANTIFEBRIN.[7]

Antifebrin is a substance new in its therapeutics, but old in its chemistry. It is phenylacetamide, or "acetanilide," long known to chemists and workers in dyes. It is made by the action of heat on acetate of aniline, and is contained in rosaniline made from acetic acid and iron. It was manufactured by Gerhardt in 1853, but its apyretic properties are the recent discovery of Drs. Cahn and Hepp, German observers, working in Kussmaul's clinic, whose announcement appeared in the *Centralblatt für Klinische Medicine*, August 14, 1886. The substance is not, like antipyrin, "protected" by patent right, and were it only equal to antipyrin as a therapeutic agent, should on that account be preferred, as well as from the resulting fact of much less cost.

Acetanilide, rechristened by Cahn and Hepp "Antifebrin," is a white, crystalline, odorless powder, slightly purgent, almost insoluble in cold water, sparingly soluble in hot water, readily soluble in alcohol. It melts at 113° C, and distils unchanged at 292° C. It has neither acid nor basic properties. The taste is not unpleasant, and it can be conveniently given in whiskey or warm sweetened water, or suspended in water. Its antipyretic action is marked and constant, and effective in much smaller doses than antipyrin, while enormously large doses do not produce toxic

effects. Its apyretic action as compared with that of antipyrin is, weight for weight, as four to one, that is, four grains of antifebrin equals in effect 16 grains of antipyrin.

The authors themselves frequently took fifteen to thirty grains a day without the least effect, while Fürbringer and Reise raised the dose to ninety grains daily without harm. It causes no cerebral disturbance, rarely any rigors with the subsequent rise, no vomiting, and the appetite improves under its use. In a few cases, cyanosis of the face and limbs has been observed, but this soon disappeared and seemed to have no unfavorable significance.

To consider briefly the clinical evidence from the points brought forward, we have a series of twenty-four cases, reported by Cahn and Hepp,[8] a later series of sixty cases by the same,[9] followed by reports from various trustworthy sources both foreign and American, including thirty cases reported by Eisenhart, Ziemmsein's clinic; twenty-nine cases by Prof. Osler, of Philadelphia, as well as results personally observed in the Boston City Hospital. A generalization of these reports and results is all that can be attempted in this article. In regard to the diseases treated: the cases reported by Cahn and Hepp were chiefly typhoid (37 cases), erysipelas, phthisis, acute articular rheumatism, and pneumonia standing next in number, with a few scattering cases of septicæmia, pyæmia, etc. Prof. Osler's cases were typhoid, pneumonia, phthisis and erysipelas. The best results were in cases of typhoid, the poorest in pneumonia, peritonitis and erysipelas, but the defect was not in the direction of untoward effect of the drug, but of simple failure on its part in ordinary doses to reduce temperature to any marked degree. Concerning the dose: a single moderately large dose once a day, preferably in the morning, seems to aid much better than small repeated doses; but when the temperature is brought to the normal by a single large daily dose, it can be held there several days by a very small single dose each day. Cahn and Hepp used first fifteen-grain doses daily, at a single dose or in divided doses close together. Later they employed seven and one-half-grain doses, except in the severer types of high temperature. Eisenhert[10] used doses of only four to eight grains, with good results. Osler employed chiefly daily single doses of eight grains.

In ordinary cases, therefore, four to eight grains would seem a sufficient dose, with no hesitancy in repeating if it should seem advisable. Thirty grains daily is regarded as an absolutely safe limit.

In regard to the method and time of action. The reports referred to show a gratifying uniformity. Temperature begins to fall in about an hour after administration, continues falling for three hours or more, the pulse at the same time diminishing in rate and increasing its tension. Perspiration generally attends the fall in temperature. There is often thirst, and very generally diuresis. The apyrexia persists four to ten hours, quiet sleep generally attending it. The amount of temperature remission is two to seven degrees. The pulse-rate often falls twenty to thirty beats. The increased tension noted is in marked contrast to the action of antipyrin and allied drugs. Cahn and Hepp give sphygmographic tracings,[11] conclusively establishing increased blood pressure, high tension pulse, under the use of antifebrin. The same point has been established in experiments with the drug on animals in Schmiedebourg's laboratory, and it was found that even when injected into the veins antifebrin did not lower blood pressure. This point cannot be too much urged as an advantage in the action of antifebrin over antipyrin, since it shows that where antipyrin depresses and weakens the heart's action and the circulation, and so becomes unsafe in many cases where it would otherwise be valuable, antifebrin stimulates and strengthens the heart and circulation, and so is beneficial in such cases, aside from its apyretic action. Thus a pulse weak and rapid from disease becomes slow, full and regular when antifebrin is given, an action closely suggesting that of digitalis, which is still further carried out in the *diuresis* so generally resulting.

Adding to this many incidental advantages observed, freedom from vomiting (even in those in whom antipyrin caused nausea or vomiting) no irritation of urinary passages, but on the contrary disappearance of albuminuria in some cases, during its use; clear head and feeling of comfort on the part of the patient, and, considering its effectiveness and exceptional safety, antifebrin seems superior to any other antipyretic drug yet discovered. [Within a few days the attention of the reporter has been called to an instance of the use by a girl of sixteen who became cyanotic after taking a teaspoonful of antifebrin. There were no other indications of any unpleasant action.]

As further evidence of anti-rheumatic action the following report of thirty cases is interesting:[12]

THIRTY CASES FROM PROF. FUBRINGER'S CLINIC:

Acute articular rheumatism	10
Phthisis	9
Typhoid	5
Pneumonia	4
Pleurisy	2

At first the daily amount of antifebrin was 2. only, later increased to 6. without bad results. In typhoid single doses of 0.5 were first tried, but later hourly doses of 0.25. The results in all cases were highly satisfactory, temperature fell, pulse became less frequent, patients did well.

In the ten cases of rheumatism the dose given was 0.5–1, the daily amount 3.–4., followed in all cases by complete disappearance of swelling and pain in three to five days. Four of these cases relapsed, three having received less antifebrin than the other cases, the fourth, a very severe case, and only given a total amount of 12.5.

The report closes with the claim for antifebrin in acute articular rheumatism, of "complete cure without the disagreeable incidental effects of salicylic acid."

ANTIPYRIN AND ANTIFEBRIN IN HEADACHE AND EPILEPSY.[13]

The use of these drugs in headache and epilepsy has recently been attracting some attention. Dr. Allan McLane Hamilton, of New York, has published an account of his experience in the *New York Medical Journal*, for May 28, 1887.

He used both drugs in cases of habitual insomnia, in doses varying from three grains to eight grains of

[13] Therapeutic Gazette, July 15, 1887, 485.

the antifebrin and ten to twenty of the antipyrin, without appreciable result, though in a case of maniacal excitement, due to nervous exhaustion and connected with moderate rise of temperature 102° F., fifteen grains of antipyrin repeated twice produced refreshing sleep and a subsidence of excitement.

There can be no doubt, however, that in wakefulness due to general disease, especially with high temperature, the value of both these drugs as hypnotics is very great. It would seem as if both remedies were of value in headaches or cerebral states attended by anæmia, or in the excitement due to cell-malnutrition and exhaustion; and though antipyrin seems to be the more serviceable remedy, it possesses drawbacks which do not belong to antifebrin. It would appear as if the remedies were valueless or even harmful in cases of organic or symptomatic epilepsy, but worthy of trial in the light cases attended by rather general cerebral vascular spasm and not much muscular movement. In several cases of petit mal, the good effect of continued doses of antipyrin and antifebrin is manifest, for the losses of consciousness are far less frequent than when the patients were under other treatment. So far as tolerance goes, he has given to one patient forty-five grains of antipyrin in two hours without ill effects.

Dr. Faust, of Dresden, recommends antifebrin in doses of from 0.5–1. gramme for headache. He noticed upon himself that migraine which defied all other remedies disappeared entirely in from half an hour to an hour's time after one of the above doses; he has obtained the same results in many other cases.

Antipyrin is also a useful remedy against migraine, according to Dr. T. S. Robinson,[14] who has used it in eighty cases during the last two years.

The cases were not selected; in fifty-four the drug acted favorably in from thirty minutes to two hours. In fifteen cases the pain was much abated, and when he resorted to chloral, bromides, or other drugs, he had to use smaller doses than the patient had otherwise been in the habit of taking. The relief was greater and the attacks generally cut short. In eight cases it had little or no effect. The reports from successful cases were all in favor of this drug, not only that it was quicker in its action, but that it did not leave the ill effects generally left by other forms of medication. He recommends that patients who are subject to attacks of hemicrania should keep powders of antipyrin of twenty-two grains constantly on hand, and that on the first symptom of the attack one powder should be taken in a little Vichy water, and repeated in two hours if the pain is not abated.

SALICYLATES.

The possible evil results of a long course of salicylic acid or salicylates, formed the subject of an interesting discussion before the French Academy of Medicine, leading to the condemnation by that body of these agents as preservatives in articles of food. The evidence adduced was certainly suggestive of possible renal disease and arterial sclerosis as a result of cumulative irritation from long continued use of the drug, even in very small amounts.

ANTISEPTICS.

Iodoform. The antiseptic properties of iodoform have been seriously called into question by two observers in Copenhagen, Messrs. Heyn and Roosing.[15] They refer to the experiments of Mikulicz, 1881, as indefinite in result, and to those of Rumuno, 1883, as complicated by the use of oil of turpentine in combination. They do not refer to the experiments of Poliakoff, 1884, whose conclusions have an important bearing on the subject: "Iodoform proves an antiseptic *only* as regards the living animal system where it finds the conditions favoring a slow liberation of iodine. Outside the animal body, under an ordinary temperature, iodoform is unable to arrest putrefactive and fermentive processes; it is otherwise under higher temperatures, setting free iodine." The experiments of Heyn and Roosing under consideration were with solutions of iodoform in olive oil and serum, and with the dry powder. They studied the effect of cultures of various bacterial organisms in these mixtures or powder, with a few experiments on animals. Their results, as reported, are sweeping and conclusive against germicide or antiseptic action in iodoform, *under the conditions named*, chiefly being in germ cultures outside the body; that they thus disprove action in the animal system cannot be accepted; although it must be added that the few experiments they report on animals, in purulent and putrefactive processes, seem also to be adverse to antiseptic action. They go a step further in affirming that iodoform itself may contain pathogenic micro-organisms and be the cause of that which it is used to avoid; a carrier of bacterial infection, with the conclusion that as antiseptic or germicide, iodoform is absolutely worthless, and as a dressing or application in surgical practice it is dangerous unless previously sterilized. These conclusions naturally lead the modern practitioner, who has seen the clinical use of iodoform and results obtained, to doubt either the reliability of the experiments, or the whole foundation of antiseptic therapeutics as a theory of micro-organism destruction, and this doubt finds expression in a letter to the *Lancet*, March 19, 1887, from Dr. Glover, of London, who says that the doubt cast on the antiseptic properties of iodoform is contradicted by the practical experience of every surgeon who employs it, and reports one of his own cases, apologizing for the apparent absurdity of reporting one of hundreds that are constantly occurring, in which a badly "poisoned hand" riddled with abscesses and foul with pus, lost all offensive character and healed rapidly under treatment with iodoform.

R. Norris Wolfenden, M.D., Cantab., in an article on "Iodol"[16] says: "I am aware that doubts have recently been cast upon the antiseptic powers of iodoform, but this scepticism scarcely accords with common experience," and a foot-note adds: "The experiments upon which this opinion is based have been declared to be unreliable." Certainly, until these adverse experiments are established as completely reliable, and their results conclusively confirmed, iodoform, *in the animal system*, where alone its action is of practical clinical importance, will continue to hold its position as a powerful antiseptic and germicide agent.

IODOL.

For some time attempts have been made to obtain a preparation of iodoform in all essential characters, without its disagreeable properties, especially its nauseous and persistent odor. Dr. Wolfenden, of the

[14] Therapeutic Gazette, June, 1887.

[15] Fortschritt der Med., January 15, 1887. Lancet, February 12, 1887.

[16] Practitioner, May, 1887, 337.

Hospital for Diseases of the Throat, in London, announces that end attained in "iodol, an efficient substitute for iodoform" (Ref. above). This substance was discovered by Silber and Ciammician, and first used clinically by Mazzoni. Chemically it is tetra-iod-pyrrol ($C_4 I_4 \dot{N} H$), a yellowish brown crystalline powder, nearly odorless, very slightly soluble in water, (1 : 5000), quite soluble in alcohol (1 : 3), very soluble in ether. Solutions darken on standing in the light or at high temperatures, depositing iodine, hence solutions should be kept in bottles of blue glass in the dark, and not exposed to high temperature. It is rich in iodine (88.9 parts by weight) which is readily liberated at body temperature. It has been chiefly used as an external application, and no toxic action has been observed even in long-continued use, an especial advantage, it is claimed, over iodoform. It is undoubtedly antiseptic, added to fluids which readily decompose; they remain undecomposed for months. Reports on its use in nearly all conditions in which iodoform has been used, show equally good results. It can be used (1) as a powder, (2) solution in alcohol and glycerine (iodol 1 part, alcohol 6, glycerine 34); (3) solution in ether (1 : 8); (4) spray, solution in glycerine and vaseline; (4) (iodol 1 — glycerine 1 — vaseline 7) to be warmed before using; (5) bougies ½ grain each; (6) iodol gauze for dressings, etc.

It is summarized as odorless (or nearly so), tasteless, producing no constitutional effects, antiseptic, anæsthetic, a promotor of granulation and healing, arresting suppuration, deodorizing foul secretions.

SALOL.

This substance is a white crystalline body, soluble in alcohol. It is a compound of salicylic acid and phenol, supposed to combine the advantages and action of its two components, and hence employed both as antiseptic and antirheumatic. It was at first thought to be safer than carbolic acid, and less irritating to the stomach than salicylic acid or salicylate of sodium. Cases, however, of constitutional effect, as from carbolic acid have been reported, so that its superior safety is open to doubt, while its advantage over salicylate of sodium in rheumatism is not yet established.

(To be continued.)

Reports of Societies.

AMERICAN GYNÆCOLOGICAL SOCIETY.[1]

TWELFTH ANNUAL MEETING.

WEDNESDAY, SEPTEMBER 14TH. — SECOND DAY. MORNING SESSION.

The PRESIDENT, in a few remarks, called attention to the death of Dr. John Scott, of San Francisco, Cal., and appointed Dr. Thomas Addis Emmet to prepare a memoir for the published Transactions.

THE THERAPEUTIC VALUE OF SOME MEDICINES IN THE TREATMENT OF HÆMORRHAGIC CONDITIONS OF THE UTERUS,

by DR. C. D. PALMER, of Cincinnati.

The author referred to the fact that very few papers on the medicinal treatment of hæmorrhagic affections of the uterus appeared in the eleven volumes of the Transactions of the Society. In hæmorrhage from the uterus, it is important to remove the cause where this can be found. The object of the paper was to speak of the value of certain internal remedies, and their field of utility.

No drug is more frequently used than *ergot*. This is beneficial in many cases, but may aggravate some. It is of service in chronic hyperæmia and in subinvolution. Its effects are less marked in nulliparæ than in multiparæ. In the treatment of uterine fibroids, between the use of galvanism and of ergot, the field of laparo-hysterectomy must be a limited one. The hæmorrhage from fungoid degeneration and from ovarian irritation is better met by other remedies. In some cases of pelvic peritonitis and pelvic cellulitis, the hæmorrhage has been increased by use of ergot.

Digitalis, in appropriate cases, is of service. It is reasonably reliable in uterine hæmorrhage due to cardiac trouble. In atonic conditions of the circulation, weak heart, and low arterial tension, which tend to induce passive hyperæmia, digitalis may be used.

Cannabis indica has been the subject of diverse claims. The drug varies much in strength. It acts more especially on the nervous system. Its indications are imperfectly defined, and its effects uncertain.

Bromide of potassium is useful in certain hæmorrhagic states. It is indicated where there is sexual excitement, and ovarian congestion and irritation. It is not so useful where hæmorrhage is due to uterine irritation, although, in some cases of fibroid tumor, the author had found it more useful than ergot.

Arsenic is of service in uterine hæmorrhage. It is not prompt in its action, but, in appropriate cases, it is effective. It acts as a tonic, stimulating all the functions, and especially those of the skin and mucous membrane. In chronic endometritis, with or without fungoid degeneration, a course of arsenic will be of material service. It is of value in the case of young girls when menstruation appears too frequently, and continues too long. In menorrhagia at the time of the climacteric, it is of service, although its effect is less decided than in the former group of cases. Arsenic is a good remedy in menorrhagia of malarial origin.

Gallic acid is the best representative of the astringent class of remedies, and has been repeatedly tested in hæmorrhage due to uterine atony. Its large dose, unpleasant taste, and tendency to disorder digestion, limit its use.

Active cathartics, particularly so-called cholagogues, as mercury, are useful in uterine hæmorrhage of hepatic or splenic origin.

It is the custom with many to use iron in the intermenstrual period. Iron tends to promote pelvic congestion, and is almost universally injurious. Where there is menorrhagia due to hyperæmia, the muriated tincture of iron is beneficial.

Viburnum prunifolium, hydrastis, and gossypium have been recommended. Dr. Garrigues has reported one hundred and thirty-nine cases of uterine hæmorrhage from various affections in which he used gossypium, with the result of relieving the hæmorrhage in one hundred and twenty-five cases.

The last remedy referred to was hamamelis virginiana. If thoroughly tried, this is usually efficacious. The author had employed this drug, with satisfactory result, for six or eight years. It is not equally potent in all cases of uterine hæmorrhage. For active, profuse hæmorrhage, it is inferior to ergot, but for slight, long-continued flux, where the blood is dark and

[1] Continued from page 318.

venous, the hæmorrhage being passive in character, it is the remedy *par excellence*. This condition occurs in flabby, subinvoluted uteri after delivery or abortion, in some forms of chronic endometritis, in chronic retroversion, and in some fibroids. He had also used it, with good effect, in several cases of vesical hæmorrhage from papilloma. The best preparation is the officinal fluid abstract, in doses of a few drops to two drachms. None of the remedies here mentioned were intended to supersede local medication, where indicated.

DISCUSSION.

Dr. Fordyce Barker, of New York. I believe that every one of the remedies mentioned is of special value in certain cases, and success in treatment depends upon a careful selection of the cases. A drug useful in one class of cases may be inert or injurious in another class of cases. Arsenic is useful where the system is broken down, and the patient is approaching the climacteric. It is useful not only from its tonic effect, but also from effect in controlling vaso-motor disturbance. It is of special value if, three or four days before each menstrual period, the patient is put on rather free doses of bromide of potassium. The arsenic is used only in the inter-menstrual period.

Where the hæmorrhage continues, and is profuse, the most valuable remedy is the fluid extract of hydrastis, combined with fluid extract of hamamelis, half a drachm of each being given. Six or eight drops of tincture of nux vomica may be added, if there is an atonic condition.

I have used viburnum prunifolium largely in passive hæmorrhage occurring at an early period of gestation, and in threatened abortion. I have found great benefit in cases toward the climacteric in the use of protoiodide of mercury, with iron and a small quantity of opium.

There is another class of cases not specially alluded to, and that is profuse hæmorrhage in very young girls, perhaps at the first menstrual period. In one of these cases, where hæmorrhage was exceedingly profuse, I relieved it by introducing a cone of alum, wrapped in a piece of linen, and passed into the vagina. This restrained the hæmorrhage. In other cases, I have relied on ergot and gallic acid, five drops of the former, with five grains of the latter, dissolved in mucilage.

Dr. Lloyd Roberts, of Manchester, Eng. I have very little confidence in any drug, except ergot, in the treatment of uterine hæmorrhage. The great point in the use of ergot is to get a good preparation. In cases of hæmorrhage at the menopause, where the uterus is flabby, and in the case of young girls, the best results are obtained by giving it in the inter-menstrual period. In malarial hæmorrhage, I have found quinine better than arsenic. Gallic acid is the next best remedy to ergot. I think that the good effects of gallic acid are due to its local action. Except in cases where the hæmorrhage is due to congestion of the ovaries, I should think that the use of bromide of potassium would be of little benefit.

Dr. W. Balls-Handley, of Melbourne. I do not see how the remedies referred to are going to act in restraining hæmorrhage. If their use is to be supplemented by operative measures, it is hard to say what does the good. Take a case of fibroid tumor: the growth is surrounded by muscular fibres. There does not seem to be the slighest impression in the minds of those who have spoken, that if these drugs can cause contraction of the muscular, they may cause the tumor to be forced towards the peritoneal cavity. I have given ergot, and I cannot say that I have had the slightest benefit from its use. We must consider the natural history of these affections. Some fibroids increase very slowly, while others grow very rapidly. I have never seen the growth of one of these stopped by the use of ergot. I have thought that I have had some effect from the action of ergot, locally applied, a piece of cotton being saturated with the fluid extract.

I would speak of one remedy; that is, the tincture of the sesquichloride of iron. Some of these women are so anæmic, that they go on bleeding simply because there is no power of contraction. In these cases, the preparation referred to, in doses of half a drachm, three times a day, is of value.

Dr. J. A. S. Grant (bey), of Cairo, Egypt. I have had but little experience with these drugs. Two years ago, I was called by a doctress to see a patient. There was a tumor, and uterine hæmorrhage recurred every ten days. The case had previously been diagnosed as fibroid tumor, and removal of the ovaries recommended. I found a history of syphilis, and, as hæmostatics had been thoroughly tried for months, I decided to use mercury. Stimulants and cinchona bark were also given. The hæmorrhage ceased, and the tumor, which was as large as a child's head, gradually diminished in size, and in three months the woman was able to return to work.

Dr. H. P. C. Wilson, of Baltimore. When I exclude cases of submucous fibroids, cases of granulations, and cases of polypi, the number of instances of uterine hæmorrhage is very small. I have very little confidence in any remedy as a hæmostatic in these cases. The most trouble is experienced in young girls commencing menstruation. In these cases, attention should be paid to the general health, the bowels should be regulated, and exercise enjoined.

Dr. James R. Chadwick, of Boston. I will speak of one remedy which I have found peculiarly efficacious, and that is Chian turpentine. I have used this in hæmorrhages from all causes, with surprising results. In one case, a young lady had been losing blood for the greater part of two years. Dilatation had been done, and curetting had been employed on several occasions. I could find no definite cause. She was given six grains of Chian turpentine, three times a day. Menstruation at once became regular, and has remained regular. I think that ergot, given between the flows, is of more service than when given during the hæmorrhage. During the flow, I am in the habit of giving aromatic sulphuric acid.

Dr. Wm. L. Reed, of Glasgow. I would merely refer to a drug which was formerly used. In certain cases, where no apparent cause could be found, and where ordinary hæmostatics failed, I have found alum of service, given in doses of twenty grains a day. When the immediate attack has ceased, I give sulphate of magnesia, with sulphate of iron. I have great confidence in arsenic where there is disease of the endometrium. I prefer the iodide of arsenic.

ALEXANDER'S OPERATION,

by Professor Dolores, of Paris.

The speaker treats cases of retroversion of the

uterus by shortening the round ligaments, where all other measures of treatment have failed. Where there is retroflexion, he first overcomes the flexion by three or four forcible dilatations, and then shortens the round ligaments. In cases of prolapse, he first restores the uterus to a normal condition. If the cervix is abnormally long, it is amputated, and the round ligaments are then shortened. Anterior and posterior colporrhaphy are also performed. In cases of anteversion, there is no need to shorten the round ligaments, as the pressure of the abdominal contents does not come upon the uterus, as in the case of retroversion. In these cases, the vaginal operation is sufficient. The object of the shortening of the round ligaments is not to suspend the uterus, but to antevert it.

DISCUSSION.

DR. WM. L. REED, of Glasgow. One of the most important points to which attention should be called, is that, even when a successful operation has been performed in a case of chronic retroversion, you must not expect the patient to feel quite well in the course of a few weeks. All that the operation does is to restore the position of the uterus. It does not alter its condition. The patient will probably be no better three months after the operation than before it, especially if care is not taken.

The principal difficulty in the operation is to find the ligaments, for, after leaving the inguinal canal, they divide extensively. If you dissect down upon the ring, a good many of these fibres are destroyed. The dissection should be made clear of the abdominal ring until the tendon of the oblique muscle is reached. Then, by pressing on the canal, a little fat is forced out. This can be picked up carefully, and the fibres of the ligament separated, and usually there is no difficulty. The after-treatment is most important. If you take a case of prolapse, with the uterus down to the woman's knees, shorten the ligaments, and allow her to be about in two weeks, you need not be surprised if the trouble is soon reproduced. The patient should be kept in bed five or six weeks, and afterwards, she should wear a well-fitting pessary for five or six months. A pessary that, before the operation, could not be kept in place one hour, will remain without difficulty after the operation.

DR. A. MARTIN, of Berlin. I have not performed this operation, but my colleagues have done it in a small number of cases. I should not object to performing the operation when a suitable case presented itself. From my experience, I am led to believe that we exaggerate the importance of prolapse. I have seen many cases where the patient suffered this displacement without discomfort. I do not think that an operation on the ligaments without restoration of the pelvic floor will give a certain hope that the uterus will be retained within the pelvis. In these cases, I perform Hegar's operation. We cannot retain the uterus in its place either by narrowing the introitus of the vagina, or by narrowing the canal. It is only by a restoration of the pelvic floor that it can be retained. Hegar's operation consists in making a strong cicatrix in the floor of the pelvis, and I have performed his operation with satisfaction.

DR. WM. T. LUSK, of New York. I have performed Alexander's operation a number of times. The operation is simple, and easy to perform, except where there is great atrophy of the abdominal walls. I consider it absolutely devoid of danger, if performed with ordinary cleanliness. There is no reason why this operation should not be employed in cases where a pessary will not remain. I have done Hegar's operation, but I have never found that the cicatrix has prevented sagging down of the uterus. If the uterus is held forward after Hegar's operation, I think that the prolapse will be overcome.

DR. C. C. LEE, of New York. I have done Alexander's operation about nineteen times. The operation is indicated in those cases where a pessary cannot be borne, on account of the abnormal tenderness of the vaginal vault, although no distinct pelvic peritonitis or cellulitis can be detected. It may be used in cases of retroversion of the uterus, with chronic salpingitis, which cannot be cured without laparotomy. It is also to be employed in a limited class of cases where there is complete procidentia, and where the usual plastic operations have failed to keep up the uterus. In such cases, where there is a laceration of the cervix, I do not attempt to do Alexander's operation without, at the same time, closing the tear. Where the uterus is bound down by adhesions, this operation is not indicated.

DR. HOWARD A. KELLY, of Philadelphia. I have done this operation for three years. It is folly to expect a heavy uterus to be held over a large open canal by two ligaments. If the cervix is hypertrophied, it must be removed. Suitable operations should be performed on the vagina. In the case of a heavy uterus, the round ligaments acting at right angles to the organ are at a disadvantage when we attempt to raise the womb. In one case, therefore, I substituted hysterorrhaphy, with entire success.

THE PRESIDENT'S ADDRESS

was then delivered by DR. ALEXANDER J. C. SKENE, of Brooklyn.

He first referred to the organization of the American Gynæcological Society, which occurred in the Hall of the Academy of Medicine, New York, twelve years ago. The Society has passed its age of development and entered upon its period of growth. The object of the organization is to promote science and art, not to regulate the relations of the profession to the public. The usefulness of a medical society depends upon its objects. When called into existence by the necessities of man, and for the benefit of the human race, it is enduring. America is notable for the rapid development of gynæcology. The first Gynæcological Society in the world was organized at Boston. Modern gynæcology is but seventy-five years old, but much has been accomplished. The advance of gynæcological surgery has been marvelous. At least ten of the most serious operations on the human body belong to gynæcology. Over seven hundred and eighty different instruments have been devised for the diagnosis of diseases of women. For the correction of displacements, there are in use some three hundred different pessaries. The growth of the literature of gynæcology has been surprising. About six thousand books pertaining to this subject have been published in the last seventy-five years, and in the last eight years eight hundred and four books and seven thousand journal articles and pamphlets have appeared. The majority of these have been devoted to surgical gynæcology. Since the discovery of the effect of germs and the means of counteracting

their influence, operative gynæcology has taken a prominent position, perhaps too prominent, but it will soon find its true level. Instead of pushing on, would it not be well to stop and consider what has been accomplished? The major portion of the time of this society has been given to surgical subjects. This should not be so. As much attention should be elicited by the discussion of a functional affection as by the report of a case in which the surgeon has removed all the organs of the body with the exception of those absolutely essential to life. There is room for more definite knowledge with reference to pathology and especially with regard to nomenclature. There are still interesting fields to be explored, and the greatest of these is with reference to preventive medicine. Gynæcology has much to accomplish in this direction. Brilliant reputations have been made by the removal of the tubes and ovaries, but little has been done in the way of preventing the diseases which lead to their destruction. In the present state of society more honor is accorded him who relieves the ills of man than is given to the one who prevents them. In obstetric medicine greater advance has been made in this direction. Vesico-vaginal fistula which formerly were very frequent, have almost entirely disappeared under modern methods of obstetric procedure.

Progress in gynæcology would be hastened by improvement in the medical press. In this country there is too much writing in proportion to the amount of thinking and practice. The most copious writers are not the most distinguished in practice.

THE TREATMENT OF THE PEDICLE IN SUPRA-VAGINAL HYSTERECTOMY,

by Dr. George Granville Bantock, of London.

The surgical treatment of fibroid tumors of the uterus has attracted a great deal of attention during the last ten years. Considerable progress has been made in the last three years, mainly in the treatment of the pedicle. In his first operation the speaker ligatured the pedicle, applied the cautery, split the pedicle into an anterior and posterior portion and brought these together with sutures. The patient died four days later of septic poisoning. It is a peculiarity of uterine tissue that it shrinks under strong pressure. In this case the ligatures soon became loose and there was oozing into the peritoneal cavity. In the next case the pedicle was tied in three portions and surrounded by a silvered copper wire and transfixed with two long needles. It was brought into the lower angle of the wound. Thirteen hours after operation there was a free flow of blood, which was arrested by the cautery. On the ninth day, as the copper wire did not make sufficient pressure, a wire ecraseur was substituted, and this succeeded in reducing the size of the stump. As now performed the operation consists of surrounding the pedicle with a soft iron wire attached to a small ecraseur by which the wire can be tightened. Before cutting away the pedicle it is important to transfix it with needles to prevent the wire from slipping. After the body of the uterus is removed the pedicle is secured in the lower angle of the wound. In some of the cases reported, the pedicle, which at the time of operation, was two or three inches in diameter, was reduced to one-third of an inch in diameter, when the wire came off at the end of the eighteenth or twentieth day. The author did not think that the operation could be improved by substituting the intra-peritoneal method of treating the pedicle. Thirteen cases of pediculated fibroids treated by the extra-peritoneal method, recovered, while two treated by the intra-peritoneal method died.

With reference to the after-treatment of the pedicle, Dr. Bantock said that if the pedicle is properly secured at the time of operation, the less it is interfered with the better. The serre-nœud should not be touched in less than four or five days, unless there is oozing, in order not to disturb the adhesion of the peritoneum. If there is bleeding it usually occurs within a few hours. If the pedicle is thick it may be necessary to tighten the wire. When the stump comes off, the dry or wet method of treatment may be employed. The former consists in dusting iodoform on the part. The latter consists in washing the part with a solution of sulphurous acid, 1 to 9, and then applying equal parts of rectified spirits and glycerine.

The author's statistics were as follows: fifty-seven cases of supra-vaginal hysterectomy with forty-five recoveries and twelve deaths. In five of the fatal cases there was pronounced disease of the kidneys. In one there was acute enteritis. In two there was hæmorrhage. In one there was obstruction of the bowel, and in two, septicæmia.

The discussion of Dr. Bantock's paper was made the first order of business for Thursday morning.

(To be continued.)

PHILADELPHIA PATHOLOGICAL SOCIETY.

W. E. Hughes, M.D., Recorder.

Stated meeting, September 22, 1887, the President, Dr. J. C. Wilson, in the chair.

Dr. W. Osler presented a specimen of

THROMBOSIS OF THE PORTAL VEIN.

Chronic obstruction to the blood-flow in the branches of the vena portæ within the liver, such as occurs in cirrhosis, is probably the most common cause of this rare condition. We not infrequently meet with atheroma in the portal vein and its branches in cirrhosis, one factor in the production of which, as in the pulmonary artery in mitral stenosis, is the heightened blood-pressure, and to this change, the thrombus-formation is closely related. At first, and possibly for a long time, mural, it gradually becomes obliterating; and if the collateral circulation is established, the patient may live some time, as in a case which I reported in 1882,[1] in which the vein was represented by a firm, fibrous cord. The specimen here shown was taken from a Swede, aged about forty-five, who was admitted to the University Hospital, May 7th, with ascites. As he could not speak English, it was difficult to obtain a history, but we ascertained that he had been in failing health for some time, and latterly, his abdomen had become swollen. It did not appear to have come on suddenly. The liver dulness was reduced, the superficial abdominal veins were moderately distinct, and the case was regarded as one of ordinary cirrhosis. He was tapped five times between May 20th and July 14th, and from twelve to fifteen pints of serous fluid removed on every occasion. He was able to be up and about after each tapping, but he gradually became emaciated, weak, finally comatose, and he died July 20th. There were no hæmorrhages,

[1] Journal Anatomy and Physiology.

and it may be stated that the abdominal veins were at no time more distended than is common in atrophic cirrhosis. The condition, post-mortem, was as follows: Fibrous adhesion in peritoneum; atrophic cirrhosis of liver, with thickened capsule; old, firm thrombus in vena portæ, extending into splenic and mesenteric veins; thickening and patchy calcification of the walls of the portal vessels; great enlargement and induration of the spleen; kidneys indurated; no special changes in thoracic organs. A careful dissection of the abdominal veins was not made, but I am told by Dr. Miall, who made the autopsy, that the peritoneum was very dark, and the veins behind the liver very large. The collateral channels were, no doubt, largely the anastomoses which exist between the peritoneal, mesenteric, and lumbar veins, and the gastric, diaphragmatic, and œsophageal vessels. As in the case of fibroid obliteration referred to, a perfect collateral circulation may be established in occlusion of the portal vein, and the patient may live for months or years. In this instance, the thrombus was evidently old, as, in places, there were calcareous changes. The branches in the liver were filled with soft clots. The gall-bladder was full of normal bile. In two other cases of cirrhosis, I have met with thrombi in the portal vein in both instances, with thickening and atheromatous changes in the vessel walls, but the thrombi had not undergone such degenerative changes as in this specimen.

Dr. H. F. Formad presented a specimen of

CHRONIC HYPERTROPHIC CIRRHOSIS OF THE STOMACH, WITH GASTRIC ULCER AND COLLOID CHANGES OF THE MUCOUS MEMBRANE.

A sailor, aged thirty-eight, a German, was admitted to the Naval Hospital, ten months ago, with the symptoms of dyspepsia and occasional vomiting. There had been absolutely no pain at any time, and no vomiting of blood. Three months before death, he began to have serious difficulty with swallowing, with œsophageal regurgitation, and though a stricture was sought for, none was found. Very curiously, for a few days immediately preceding death, he swallowed well. Death resulted from starvation. At the autopsy, the abdominal cavity was found to contain fifty-two ounces of straw-colored fluid, and showed evidences of old peritoneal inflammation, especially at the upper part, where the organs were matted together into one mass. The stomach was quite contracted, having a capacity of four to five ounces. Its walls were one-half to one inch thick, the thickness greatest at the cardia, and gradually decreasing till within two inches of the pylorus, where the wall abruptly resumed its normal condition. The first impression given was that it was a case of cancer, but closer examination showed it to be simply great thickening of the wall, with polypoid elevations of the mucous membrane, and secondary colloid change. The ulcer was situated in the posterior wall, near the cardia, its bottom formed by scar tissue in the spleen, and the peritoneal coat of the transverse colon. Communication with the abdominal cavity had been prevented by firm adhesions. The omentum contained a number of colloid granules as large as peas. The abdominal lymph-glands appeared to be amyloid. The case was remarkable, first, in the complication of hypertrophy with gastric ulcer, which was a condition that the reporter had never before seen; second, in that the hypertrophy should commence at the cardia, instead of at the pylorus.

Also,

A STAB-WOUND OF THE ABDOMEN.

Laparotomy had been performed, and a wound of the intestine found, which was sutured. The man died suddenly, sixty hours after the operation. At the autopsy, there was only a very slight amount of peritonitis found, and the wound in the intestine had firmly united. The abdominal condition not being sufficient to account for death, the brain was examined, and a very distinct embolus in the floor of the fourth ventricle found. The stomach had not been touched, but on its peritoneal surface were some slight tears, and opposite them, in the mucous membrane, but not corresponding exactly with them, were several distinct, small, linear ulcers, which appeared like ulcers due to some injury. They did not look at all like ordinary ulcers, but still had evidently formed *ante-mortem*. There was an old hæmorrhagic infarct of the kidney.

Dr. Osler had been particularly interested in the specimen, and had hoped that possibly it might prove to be related to the formation of gastric ulcer in the way pointed out by Dr. Baumgarten, and to which he wished to call attention; namely, that the movement of the stomach against the costal edges produces distinct localized thickenings, and that, in corresponding points of the mucous membrane, ulcers form.

Also,

A GUN-SHOT WOUND OF THE HEART.

The ball had entered the chest, between the fourth and fifth ribs on the left, passed through the left ventricle, and was found imbedded in the spinal column. Death was instantaneous. The principal point of interest lay in the fact that the ball had traversed the cavity of the left ventricle, near its base, without injuring the chordæ tendiniæ, or the leaflets of the mitral valve.

Dr. Wescott presented a

MEDIASTINAL TUMOR,

removed from a man, aged twenty-eight, who had entered the University Hospital a week ago. He was a brakeman, with good family history and personal habits, and no venereal history. He had been in good health, and at his work, till last July, when dyspnœa developed, and he quit work. About the same time, he noticed a tumor in his neck. There was no pain nor difficulty of swallowing. On admission, he was in a condition of orthopnœa. Over the left side of the chest there was complete dulness, extending to the right edge of the sternum, with absence of respiratory murmur. The apex-beat of the heart could not be seen or felt. The tumor of the neck involved the superficial lymph-glands, and could be traced behind the sterno-cleido-mastoid muscle, and down into the chest. There was no inequality of the pupils, and no œdema. At the autopsy, on opening the chest, nothing but a large, fleshy mass and the edge of the right lung could be seen. The mass penetrated the chest-wall, between the first and second ribs, and became continuous with the tumor in the neck. It was closely attached to the bodies of the dorsal vertebræ from the first to the fourth, filled all the upper part of the left chest, and completely enveloped the great vessels. The œsophagus was pushed to one side, but not compressed. The left lung was completely collapsed, and

contained numerous secondary nodules. The heart was pushed down and back, but was normal. The mesenteric glands were enlarged. A section of the tumor showed largely fibrous tissue. The reporter asked whether, in the case of such a large mass, the absence of pressure symptoms was not remarkable.

DR. J. B. WALKER said that in the absence of pressure symptoms, such a large tumor was, in his experience, unique, generally very much smaller ones giving rise to marked symptoms.

NEW YORK STATE MEDICAL ASSOCIATION.

FOURTH annual meeting, held at the Hotel Brunswick, New York City, September 27th, 28th, and 29th, 1887.

FIRST DAY — MORNING SESSION.

The report of the Committee of Arrangements was read by DR. CHARLES A. LEALE, in which he extended to the members a hearty welcome.

THE PRESIDENT'S ADDRESS.

DR. ISAAC E. TAYLOR then proceeded to read his address, in which he spoke of the past success of the Association, of the indications of continued success, urged upon the members the full discharge of the duties devolving upon them individually, and gave expression to feelings of sorrow at the loss by death of several worthy and prominent members.

Turning, then, to the main subject of his address,

LUPUS SERPIGINOSUS OF THE CERVIX UTERI AND GENITALIA OF WOMAN,

Dr. Taylor described a case which had come under his observation, and presented a cast of the external organs. The disease began in the cervix and was first seen by him in 1885. Its course was interrupted by a period of comparative health; it then renewed its activity, extended to the vulva where it was manifest in the hypertrophic form, involved the clitoris and urethra, and finally ended in the death of the patient.

The rarity of this affection of the female genitalia, the fact of its existence being doubted by some, the differential points from cancer, tubercular disease, etc., were dwelt upon. It remained to determine whether the disease was due to a special organism. The treatment was as unsettled as in former years, and varied according to the views of the physician having charge of the case and the symptoms manifest. A principle to be borne in mind in the treatment, was not to do injury to the healthy tissues beneath and around the diseased part. In this case the escharotics had been abandoned for solutions of nitric acid.

THE USE OF HOT WATER IN SURGERY.

DR. THEODORE R. VARICK, of Jersey City, read this paper as supplementary to two which he had read the past three years at other meetings, one of this association. His intention was to reply to criticisms and to give further statistics in support of the method. The water employed by him was only a little below the boiling point. It was brought from the boiling kettle, and applied by means of a clean sponge or linen cloth dipped into the hot water and applied to the operation wound; and when applied was probably of a temperature of about 188°F. Its effect was to coagulate the albumen, and hermetically seal the bloodvessels against the entrance of germs or extraneous matter. As long as bleeding was active, there was little danger of sepsis, but when oozing ceased, if the vessels were not sealed, there was danger of the absorption of germs. Hot water was also a cardiac stimulant, and counteracted the shock which was present in greater or less degree in all major operations.

Dr. Varick gave the statistics of mortality after amputations by different surgeons in as many as six thousand cases, the mortality averaging thirty-two per cent., *plus*. Of fifty-three amputations performed by him since 1879 in which he applied hot water to the wound, there had been only three deaths, or a mortality of less than six per cent. Most of the cases were railroad injuries. In one of the cases death was due to angina pectoris, in another to secondary hæmorrhage, and in only one to septicæmia, arising, he felt confident, from the other wounded foot which was not operated upon. Dr. John D. McGill had amputated in twelve cases, applying hot water, without a death. It was not sufficient to apply the water warm, as some who failed to understand the principle of the treatment had done.

A vote of thanks was extended Dr. Varick, a resident of New Jersey, for his paper.

BI-CHLORIDE OF MERCURY; ITS USES AND ABUSES.

DR. CHARLES S. WOOD, of New York, thought that this powerful drug, unless its use was surrounded by proper restrictions, would do more harm to the human race than good. Some years ago, before its germicidal properties came into prominence, he had employed it in certain cases of phthisis, with, he believed, good effects. While it had not been shown to possess the power of killing the bacillus tuberculosis when taken internally, he thought it probably exerted a beneficial influence in counteracting the effects of the ptomaines developed by these.

Another class of cases in which it had been of utility in his hands, were those of Bright's disease. In several cases he attributed to it the effect of relieving symptoms and prolonging life, and enabling the patient to go about his duties with comfort. Its use in syphilis was touched upon, as well also in surgery. He cautioned against the too frequent and careless use of bichloride of mercury both in internal administration and in surgical dressings. It could never arrest any disease of acute or infectious character by killing germs after internal administration; for, given in sufficient doses to effect this object, it would first kill the patient.

A CONTRIBUTION TO THE STUDY OF HIP-JOINT DISEASE.

DR. NATHAN JACOBSON in this paper favored the view that hip-joint disease usually had traumatism back of it, and that accompanying pulmonary tuberculosis did not necessarily mean the hip-disease was primarily tubercular in origin. In one of two cases which he related there were signs of pulmonary tuberculosis which cleared up with disappearance of joint symptoms following operation, and he said that whether the pulmonary trouble was secondary to the affection of the joint, or whether they were concomitant but independent affections, must remain a matter of conjecture. That the disease of the lung was

largely influenced by the joint disease, he was convinced. The existence of tuberculosis of the lungs should not be a contra-indication to operative procedures in hip-joint disease. One case was cited illustrating a class which would do best under rest and hygienic measures.

FIRST DAY.— AFTERNOON SESSION.

DISCUSSION ON THE MANAGEMENT OF COMPOUND DISLOCATION OF THE ANKLE-JOINT.

Dr. E. M. Moore opened the discussion by a paper in which he showed by extracts from Astley Cooper, and writers from his time down to the present, that there had been manifested here and there a tendency to adopt more conservative methods of treatment in compound dislocations of the ankle-joint. This tendency to conservation, however, had been too little marked, and even at the present day had taken a less firm hold on surgeons than it should. Dr. Moore referred briefly to five cases which had come under his observation, in none of which had he found it necessary to perform primary amputation, and in none had there been a fatal issue. Four recovered with useful limbs: in one the dressing exerted some compressing effect and led to gangrene, and amputation was performed. The patient recovered. An ideal result was obtained by a friend in the case of an elderly lady who recovered with apparently a perfect limb, as shown by a cast, and who was able to walk without a limp. It would have to be a severe case to lead him to do amputation in the first instance. Where practicable he would choose Syme's amputation.

Dr. Uri C. Lynde discussed the question

WHEN SHOULD AMPUTATION BE PRACTISED, AND WHEN SHOULD OTHER METHODS BE EMPLOYED?

In answer to the first part of the question, Dr. Lynde said that of modern writers only a few had been specific enough in the expression of their views for them to be of any value. From his own experience he divided the cases into two classes. If there was only contusion in connection with the dislocation, and that contusion were confined to one side of the ankle, and covered a limited surface, we should not amputate, although sloughing might take place, but if the contusion were extensive, on both sides of the ankle, and especially if the injury of the bones were severe, it would be our duty to amputate at once. If the injury to the bones was not extensive in connection with rupture of the posterior tibial artery, the case should be treated conservatively; if the injury to the bones was marked, the astragalus being comminuted, rupture of this artery would suggest the propriety of amputation. The same rule applied in connection with rupture of the anterior tibial artery. While surgeons would not, owing to rupture of the nerves alone, amputate, yet this accident might, in a particular case lead to an unfavorable result.

With all the safeguards of modern treatment thrown around it, primary amputation is not without danger. It was fair to state that modern surgery had done, and could continue to do, more toward rendering amputation safe than it had, or could, toward rendering conservative methods safe. But if the surgeon failed to save the foot, there still remained a chance for secondary amputation. If he made a mistake it should rather be on the side of conservatism.

IF AMPUTATION IS TO BE PERFORMED, AT WHAT POINT SHOULD IT BE MADE TO RENDER THE STUMP MOST USEFUL, THE RISKS TO BE ENCOUNTERED BEING EQUAL?

Dr. Joseph D. Bryant, of New York, read a brief paper in discussion on this subject. He thought the choice lay between two methods: first, Syme's amputation, second, amputation at the junction of the middle and lower thirds of the leg. Which of these two ought to be selected was a matter, he thought, which could quite easily be determined. Syme's amputation should be selected in all cases when the vitality of the soft parts would warrant a reasonable belief that a serviceable stump could be procured by usual flap procedure. If, when amputation of the leg was performed, the bones were divided just above the malleoli the stump would not be oval; a stump would be formed with a bulbous extremity, which would require an artificial limb with a carefully fitting socket. The conclusions drawn by Dr. Bryant had been concurred in by several gentlemen engaged in the manufacture of artificial limbs. Pyrogoff's amputation was most objectionable from this standpoint.

Dr. Charles W. Brown discussed the question:

SHOULD THE LUXATION BE MERELY REDUCED, OR SHOULD SOME BONY TISSUE BE REMOVED, AND IF SO, HOW MUCH?

He said that bone should be removed when it is protruding considerably, and cannot be returned to its normal position without further injury to the soft parts, or when a portion of the periosteum has been removed, or when the head of the bone has been crushed or broken. As to the amount of bone to be removed, much would depend upon the nature of the injury. If the articulating surface of bone is pushed completely out through the soft parts, the safest plan is to saw it off; but if dislocation is not complete, and the joint is simply torn open, the wound should be thoroughly cleansed and dressed antiseptically without the removal of bone.

WHAT DRESSING AND AFTER-TREATMENT WILL CONDUCE TO THE BEST RESULT, WITH THE LEAST RISK, TO THE PATIENT?

This subject was discussed by Dr. Frederic S. Dennis, of New York. He said: It is assumed that the question of amputation has been considered, and amputation is not to be employed. Where conservatism is to be practised, partial resection may be resorted to to put the wound into an aseptic condition. The foot, toes, ankle, and leg should be washed, scrubbed, shaved, and irrigated, preparatory to examination of the wound. Enlarge the original wound, explore thoroughly the interior of the joint, make a counter-opening. All loose pieces of bone, cartilage, and foreign bodies should be removed, loose tendon, fascia, or muscle cut away, the joint thoroughly irrigated with warm solution of bichloride of mercury. A rubber drainage-tube should be carried directly through the cavity. Some surgeons, however, thought a counter-opening should not be made. The joint being free from extraneous matter, wet towels, wrung out of bichloride solution, should surround the parts. If tendons showed resistance in reduction of the dislocation, they should be divided subcutaneously, in order to secure rest of the joint. The splint should depend upon the special circumstances arising in each case.

In the majority of cases, he thought the plaster-of-Paris bandage should be employed. The danger of its being applied too tightly could be avoided by the use of cotton. After a final irrigation, iodoform should be sprinkled over the wound, a thin strip of iodoform gauze be put over the wound, a wet bichloride bandage of double-fold placed on the ankle and leg, and a layer of borated cotton, held on by bandage. Over this, plaster-of-Paris could be snugly applied, the dressing underneath affording ample elasticity to prevent constriction from inflammatory swelling. Four strips of iron might be used to strengthen the plaster-dressing. At the expiration of three days, a fenestrum should be cut at the side of the drainage-tube, and when the tube was withdrawn, it should be done under continuous irrigation. The advantages of this splint are: complete immobility; freedom to move in bed; to dress the wound without disturbing the bones; uniform and comfortable compression, to prevent infiltration; comfort to the patient during healing; convenience to the surgeon during after-treatment.

A CASE OF CYSTITIS TREATED BY COLPO-URETRO-CYSTOTOMY, IRRIGATION OF THE PELVIS OF THE KIDNEY, AND INTRA-VAGINAL DRAINAGE.

DR. NATHAN BOZEMAN, of New York, read a paper with this title, which was supplementary to one read at the Ninth International Medical Congress. By means of the new instrument devised by him, urine passing through a vesico-vaginal fistula could be carried to the urinal without coming but to a limited extent in contact with the walls of the vagina, and without injurious effects. During experiments with this method, he had opportunity to pass a rubber catheter up through the ureter into the pelvis of the kidney, and repeatedly irrigated that organ, which was the seat of disease. The procedure was not difficult, was not painful to the patient, and could be practised with safety. His patients had returned to their homes immediately after such an irrigation. The method opened a new field in the treatment of diseases of the kidneys. It was free from the objections pertaining to nephrotomy and nephrectomy.

DR. H. D. DIDAMA then read a paper on

METHODS OF APPLYING COLD.

A review of ordinary methods having been given, he described his own, which was effectual, comfortable to the patient, and inexpensive. A rubber sheet was laid upon a mattress; on one side of this, a folded cloth, wrung out of cold water; also a pillow; another rubber sheet — an ordinary sheet, on which the patient lay. When necessary to renew the cold, cloths wrung out of cold water should be placed between the rubber sheets on the other side of the bed, and the patient be lifted over by wooden bars rolled up in the edges of the sheet.

GALL-STONES.

DR. ROBERT H. SABIN, himself subject to gall-stones and biliary colic, read the paper, in which he took the ground that gall-stones formed only during an alkaline state of the system, as indicated by the alkalinity of the urine. His treatment was by bichloride of sodium, taken in water at intervals during the day, until the urine became alkaline. An interesting case was cited, that of a woman who, at times, passed as many as a teacupful of gall-stones, the size of hulled peanuts, and closely resembling these.

(To be continued.)

Recent Literature.

Sphygmography and Cardiography. By ALONZO T. KEYT, M.D. Edited by Asa B. Isham, M.D., and W. H. Keyt, M.D. New York and London: G. P. Putnam's Sons. 1887. pp. 229.

The late Dr. Keyt was well known as the inventor of a compound sphygmograph, and as a contributor to the periodical medical press of articles on the application of the graphic method to the study of the cardiac and arterial circulation in health and disease. His premature death doubtless prevented him from the presentation of his work in a connected treatise, such as that which his friend and his son have prepared. "Nothing more is assumed on the part of the editorial supervision than that it presents Dr. Keyt's work in an available shape to the profession."

The book includes two parts, the first physiological, comprising 148 pages; the second clinical. Keyt's compound sphygmograph is fully described and figured. It traces pulsations of the heart itself, of any accessible artery, of the fontanelle, of pulsating tumors. But it does far more than this, for simultaneous tracings can be taken on the same plate of, for instance, the cardiac and peripheral pulsations, the relation of which to one another as regards time is recorded by a chronographic tracing. It is readily converted into a pneumograph or plethysmograph, and can be used as a kymograph. The main difference between Keyt's and Marey's compound sphygmograph is that the former uses water where the latter uses air to transmit the pulsations.

The value and the limitations of the simple sphygmograph are well set forth by Broadbent in his Croonian Lectures on the pulse, delivered in London during the past winter. The compound instrument has already made important additions to our knowledge of the circulation in health and disease, and promises more in the future.

Among the subjects dealt with in the physiological section are the velocity of the pulse-wave and the causes of its variation; the relation of the ventricular systole and diastole to each other, and the presphygmic interval — the portion of the systole between the commencement of ventricular contraction and the opening of the aortic valves. This interval varies slightly in the same healthy person at the same sitting with the same pulse-rate; more notably in different healthy persons with the same pulse-rate; but corresponds pretty closely with the pulse-rate, shortening in general as the pulsations shorten.

To turn next to the clinical portion of the work, the author confirms the observation first made by Franck, that, contrary to the opinion generally current until within a few years, in free aortic regurgitation the retardation of the arterial on the cardiac pulse is shortened, the presphygmic interval being largely lost. The presence of this sign is positive evidence that regurgitation takes place throughout the diastole — is complete — provided only that active febrile movement is absent; the value of the sign is not impaired by the presence of concomitant valvular lesions.

Aortic aneurism, on the other hand, generally causes increased retardation of the arterial pulse.

So, likewise, in mitral regurgitation, there is delay in the arterial pulse, and the amount of the delay is proportional to the gravity of the lesion. If this ob-

servation proves to be correct, we are furnished with precious means for determining more precisely the significance and importance of many apex systolic murmurs.

We have thus all too briefly touched upon some of the striking features of this work, all of which is worthy of careful study. We have mentioned only some of the author's conclusions. For the steps leading to these conclusions we must refer those who are interested to the original. The style is simple and clear, and the work is one which does honor to American medicine. A good table of contents does not take the place of a good index. The publishers have done their share in a manner which silences criticism.

F. C. S.

A System of Gynecology by American Authors. Edited by MATTHEW D. MANN, M.D. Vol. I. Philadelphia: Lea Brothers & Co. 1887.

A more than usual interest has been felt in this work, the first volume of which has just appeared. More comprehensive systems of both medicine and surgery have from time to time been published and have attained marked success. This is, however, as far as we know, the first attempt to subdivide a special and limited branch of medical science among different authors. Until the present decade it would hardly have been possible to successfully carry out such a project, both from the lack of a sufficient number of competent men, and also on account of a too wide divergence of views of pathology and treatment. To-day, however, thanks to the impetus which has been given to the study in this country, of this branch of medicine by what may be called the New York School, emanating largely from the New York State Womans' Hospital, and to the extent and zeal with which the results of the marked progress made in gynecology in Europe have been appropriated and used, it has been possible to find a sufficient number of observers to write a thorough and well-rounded system of gynecology.

The inherent difficulty with an undertaking of this kind, is that with so full a subdivision of a necessarily limited field, the various parts will be so exhaustively treated, and approached from so many standpoints, that there will be a great deal of unnecessary repetition, and the thread of continuity will be broken, so that we shall have a series of monographs, instead of a connected and harmonious whole. That this difficulty has been wholly avoided in the work under consideration can hardly be affirmed. At the same time there is more unanimity in the treatment of the various divisions than might have been expected. The result is a book which fills its niche in the medical literature of the day, not as a work for students, but primarily as crystallizing and epitomizing the present status of gynecology, and secondarily as a book of reference for specialists and general practitioners. It is our opinion, however, that the latter class will find simpler and less bulky treatises answer their purpose better.

Its scope and size have admitted of very thorough treatment of each individual subject, and in the majority of instances foreign sources of information have been largely drawn upon, or duly noticed. It will not be possible in the limits of a short review to criticise each article. A list of the subjects of the various articles and their authors will, however, indicate the extent and character of the work.

The book opens with a "Historical Sketch of American Gynecology," by Dr. E. W. Jenks, in which the author has, with a great deal of pains collected numerous important and interesting facts with regard both to individual workers in this field, and to societies and institutions. The next article is one on "The Development of the Female Genitals," by Dr. H. J. Garrigues. Then follows a very thorough and painstaking article on "The Anatomy of the Female Pelvic Organs," by Dr. H. C. Coe. He very wisely includes the anatomy of the urinary tract and the rectum, both of which are so often complicated in affections of the genital organs proper. The subject of "Malformations of the Female Genitals," is clearly treated of by Dr. Garrigues, who has added to the value of this, as well as his former article on "Development," by appending a list of books referred to. The article on "Gynecological Diagnosis," by Dr. E. H. Grandin, is clear and comprehensive. Dr. E. C. Dudley has in his article on "General Consideration of Gynecological Surgery," grouped a great many important facts which are usually scattered through the ordinary textbooks, and the result is a valuable contribution.

"General Therapeutics," by Dr. A. J. C. Skene draws attention to the fact that much may be accomplished by general, as distinguished from local treatment, even in purely gynecological affections. Dr. A. D. Rockwell contributes an interesting article on "Electricity in Gynecology," showing how wide the application of this agent is, and giving simple rules for the use of the various currents. "Menstruation and its Disorders," by Dr. W. Gill Wylie, and "Sterility," by Dr. A. Reeves Jackson follow, the latter giving a very thorough *résumé* of the subject. "Diseases of the Vulva," is clearly and exhaustively treated of by Dr. M. D. Mann.

The important chapter on "Inflammatory Affections of the Uterus," by Dr. C. D. Palmer, embracing as it does such frequent and important diseases as acute and chronic endometritis, acute and chronic metritis, and ulceration and degenerations of the cervix, is well abreast of the times, both as regards pathology and treatment. Dr. T. A. Reamy has admirably described "Sub-involution of the Uterus and Vagina," and we are glad to see the latter half of the subject, namely, sub-involution of the vagina, accorded its proper recognition in gynecological literature as a factor in affections of the vagina following and incident to parturition. "Periuterine Inflammation," by Dr. R. B. Maury, and "Pelvic Hæmatocele and Hæmatoma," by Dr. E. Van de Warker, complete this vol ume.

On the whole, the editor and his co-workers may be congratulated on the degree of success they have attained in this important undertaking. The publishers have done their share, and the letter-press and binding are all that could be desired.

— Dr. S. P. Neklevitch, of Lozki, Russia, in the one hundred and ninth year of his age, and still in the active practice of his profession, dropped suddenly dead recently, while in the act of writing a prescription for a patient. If the physicians in Russia will persist in holding on to their patients so far into the second century of their existence, there is little wonder that so many medical students become Nihilists.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 6, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

HEMIANOPSIA AND THE CENTRES FOR VISION.

THE work of the last two years has done much to establish our knowledge as to the localization of the visual centres in the cerebral cortex. Von Graefe's original claim that these centres were in the occipital lobe, and that each centre presided over vision in one-half of each eye, was attacked from a clinical standpoint by Charcot, and from an experimental standpoint by Ferrier. Charcot[1] in 1875, asserted, from the study of cases of hysterical amblyopia, that there must be a double decussation of the fibres of the optic tract, so that the fibres from the retina of one eye should all meet in a common centre in the opposite hemisphere. The following year Ferrier[2] published his experiments upon the brains of monkeys and other animals, which seemed to show that this centre was situated in the angular gyrus, destruction of which produced blindness in the opposite eye. The removal of the occipital lobes, the angular gyri being intact, he found was without effect on the faculties of special sense. The views of Charcot and Ferrier, although they gained credence, in France and England, were not long after opposed by Munk,[3] who became convinced that the centre of vision was not in the angular gyrus, but in the occipital cortex. In the dog, where there is supposed to be a complete decussation of the optic tracts, destruction of the cortex over one side of the occipital lobe produces blindness in the opposite eye, but in the monkey and presumably in man, where there is only a semi-decussation, destruction produces hemianopsia. In both dog and monkey a partial destruction of the occipital cortex produces soul-blindness, and complete destruction on both sides produces absolute blindness.

Since that time German writers have generally accepted Munk's views, while careful study of disturbances of vision from the clinical and pathological stand-points has of late brought forward a mass of evidence in favor of them that is convincing. Darkschewitsch and Forel have not found any anatomical traces of a double decussation, while Seguin,[4] who has made an elaborate study of the literature of all cases where visual disturbances of central origin have been followed by an autopsy, has failed to find a case which proves Charcot's hypothesis of a double decussation of the optic tracts and of a centre for monocular vision,—in other words, he has failed to find a case of unilateral amblyopia from cerebral disease. His conclusions are so important that we give them in full.

"(1) Lesions in the mesal aspect of the temporal lobes or even in other basal districts of the hemispheres may give rise to hemianopsia indirectly by pressure upon the primary optic centres, the optic tract, or the chiasma.

"(2) Lesions of the corpus geniculatum laterale, the pulvinar, and the lateral caudal parts of the thalamus may cause hemianopsia, usually in association with hemianæsthesia and hemiplegia, or hemianæsthesia alone.

"(3) Lesion of the white substance of the occipital lobe in the caudal radiations of the internal capsule may cause hemianopsia alone or with hemianæsthesia.

"(4) Lesions of the supra-marginal gyrus, the angular gyrus, and the inferior parietal lobule, with the subjacent white substance, may cause hemianopsia with or without other symptoms, such as hemiplegia, loss of muscular sense, or word-deafness.

"(5) A lesion of greater extent, involving the speech centre, the motor convolutions, and the parts named above (under 4), due usually to embolism or thrombosis of the entire Sylvian artery, will, when on the left side, produce aphasia, alexia, hemianopsia, and hemiplegia.

"(6) Lesions of the occipital lobe, both cortex and subjacent white matter, produce blindness when bilateral, and hemianopsia when unilateral (agreeing with Exner).

"(7) A lesion of the cuneus and adjacent fifth temporal (of Ecker) on one side, will produce lateral hemianopsia of the opposite side."

From these conclusions he derives the following data for diagnosis:

"(1) Lateral hemianopsia is always due to an inter-cranial lesion on the opposite side from the dark fields.

"(2) Lateral hemianopsia with immobility of the pupils, optic neuritis, or optic atrophy, especially with symptoms of disease of the base of the brain, is due to a lesion of one optic tract, or of the primary optic centres of one side.

"(3) Lateral hemianopsia or geometric sector-like defects with hemianæsthesia and hemichorea or hemiataxia, without marked hemiplegia, is probably due to a lesion of the caudo-lateral part of the optic thalamus, or of the caudal division of the internal capsule.

"(4) Lateral hemianopsia with complete hemiplegia

[4] E. C. Seguin. A Contribution to the Pathology of Hemianopsia of Cerebral Origin. Journal of Nervous and Mental Disease, Jan., 1886.

(becoming spastic later) and hemianæsthesia, is probably due to an extensive lesion of the internal capsule in the knee and caudal part.

"(5) Lateral hemianopsia with typical hemiplegia (spastic), aphasia (if on the right), and with little or no anæsthesia, points to a superficial lesion of the region of the middle cerebral artery.

"(6) Lateral hemianopsia with moderate loss of power in one half of the body, especially with impaired muscular sense, is probably due to a lesion of the inferior parietal lobule and angular gyrus, with the subjacent white substance, deep enough to involve the optic fasciculus.

"(7) Lateral hemianopsia alone, without motor or common sensory symptoms, is due to a lesion of the cuneus only, or of the cuneus and the gray matter immediately surrounding it on the mesal surface of the occipital lobe in the hemisphere opposite the dark fields.

"In the last five cases the pupils are normal and the ophthalmoscope rarely shows any changes."

Seguin, therefore, believes that the cuneus is the true visual centre. The anatomical relations of the optic fasciculus, lying immediately beneath the angular gyrus, show why lesions of the gyrus often cause disturbances of vision. Hun,[5] while holding to Seguin's views in the main, has sought to elaborate them, by claiming that the fibres from the upper quadrant of the retina terminate in the lower half of the cuneus, and the fibres from the lower quadrant in the adjacent part of the median occipito-temporal convolution.

Although Ferrier,[6] in the second edition of his work, has not taken account of the work of Seguin, and has taken every occasion to deride the work of Munk, he has, nevertheless, abandoned his former position. The visual centres are no longer placed by him solely in the angular gyrus, but in the gyrus and the occipital lobes combined. He believes, moreover, that the angular gyrus is the centre chiefly for vision in the opposite eye, while the occipital lobe is the centre for the opposite halves of the two eyes, and he denies that any case of hemianopsia from lesion of the occipital lobe alone has ever been reported — a manifest error in view of Seguin's work.

Since then our knowledge of the subject has been increased by the work of Wilbrand[7] and Reinhard.[8] Wilbrand believes that there are three layers of cells in the occipital cortex that form the visual centres, the outer layer being the centre for the color sense, the middle for the sense of space, and the inner, deeper layer for the perception of light. With this theory Reinhard, from a series of careful clinical and pathological observations agrees, and he adds many valuable conclusions. Lesions of the occipital lobes cause direct disturbances of vision, either soul-blindness or cortex-blindness, that is, absolute blindness; while lesions of the parietal lobes cause only indirect and temporary disturbances. If the lesion be superficial there is loss of perception of form and color, and soul-blindness, but if it be deep there is also loss of perception of light — total cortex-blindness. These two forms of blindness are seen chiefly in lesions of the convexity of the occipital lobe, and the point in it that corresponds most exactly to the macula lutea is in the neighborhood of the second occipital convolution.

As will be seen, Reinhard and Seguin place the visual centre in different parts of the occipital cortex, and Reinhard's centre is more nearly in accord with the centre discovered by Munx in the dog. Although the exact location of the centre in the occipital lobe may still be regarded as a matter of doubt, the weight of pathological evidence in man is in favor of Seguin's theory that it is in the cuneus, rather than in the second occipital, and the idea that the angular gyrus itself is in any way a centre for vision is now well-nigh abandoned except by Ferrier and his followers, and Charcot's old diagram of the double decussation of the optic track, which has so long done service in the text-books, must at last be discarded.

HOUSE-FLIES AS CARRIERS OF TUBERCULOUS CONTAGION.

SPILLMAN and Haushalter have recently reported to the Academy of Sciences (Paris, Session August 16th) their investigations as to the possibility of "contagion" (bacillus) of tuberculosis being carried by house-flies, and the results make it extremely probable that these pests of our dwelling-houses and hospital wards may have much to do with the propagation and dissemination of such contagion.

These investigations included repeated examinations made of the excrements and intestines of flies that had fed on the contents of the spit-cups of consumptive patients; in both, they found abundance of tubercle bacilli. They also found the same bacilli in the dried excrements of flies scraped from the windows and walls of rooms occupied by phthisical patients. The experimenters show how easily such germs may be disseminated by the dried excrements, or even by the dessicated and pulverulent remains of the bodies of these insects; how easily the air of respiration, or the food and drink, may be thus polluted and infected. It is known that the germs of the tubercle bacillus have great tenacity of life. These observations also indirectly strengthen the belief that the suitable soil is quite as essential to the development of tuberculosis as the suitable seed, otherwise the disease would inevitably be far more common even than it is.

Spillman and Haushalter, as a practical deduction from these investigations, insist on the importance of thorough disinfection of the spit-cups of tuberculous patients, by means of strong solutions of phenic acid or corrosive sublimate.

MEDICAL NOTES.

— Dr. St. John Roosa's work on the ear has been translated into German by Dr. Ludwig Weiss, and will be published early in the coming year, in Berlin, by Hirschwald, unter den Linden.

— A four-year-old boy, named Albert Kirkham, living at Lancaster, Eng., was severely bitten by a mad dog about the 1st of August last. He was taken at once to Paris, and treated by M. Pasteur. He returned to his home August 25th, and was taken, the next day, with premonitory symptoms of hydrophobia. He was removed to the Lancaster Infirmary, and died in great agony.

— A "Journal of Animal Morphology," edited by C. O. Whitman, Director of the Lake Laboratory, Milwaukee, Wis., has been established, devoted principally to embryological, anatomical, and histological subjects. Cordial promises of support have been received from many of the most eminent investigators in this department. This journal will be issued in the best style, with elaborate lithographic plates, and will be published by Ginn & Co.

— The women in the Sultan's seraglio at Constantinople have just been vaccinated, to the number of one hundred and fifty. The operations, reports one of our foreign contemporaries, took place in a large hall, under the superintendence of four gigantic eunuchs. The Italian surgeon to whom the task was confided was stationed in front of a huge screen, and the women were concealed behind it. A hole had been made in the centre of the screen, just large enough to allow an arm to pass through, and in this manner, the arms of various colors and sizes were presented to the operator in rapid succession. It was utterly impossible for the surgeon to get a glimpse of his patients; but, in order to guard against the chance of his being able to see through the screen, two eunuchs who stood by the operator threw a shawl over his face the instant an operation was concluded, and did not remove it till the next arm had been placed in position.

— The eminent Professor Nothnagel, we learn from our foreign exchanges, experienced an almost miraculous escape from death recently. He had been summoned to a consultation in Moscow, and, his professional mission over, he had entered a sleeping car on his homeward journey on the night of August 20th. He had barely settled down in bed when he had occasion to leave his *coupé*, and, after making his way along the passage, opened the wrong door and fell out upon the rails. Strange to say, he alighted without further injury than a slight bruise on one of the temples, and another on the foot. He found himself, bareheaded, and in the scantiest night gear, on a dark, rainy night, at a lonely spot — no one in the train, it seems, having been aware of his fall. With great difficulty and discomfort, and in the midst of a storm, he reached the house of the nearest guardian of the line, and was by him accompanied to the Iwanowka station; thence he got by train to Dünaburg, where the station-master gave up to him his clothes and travelling effects, as well as his pocket-book, containing more than ten thousand roubles, also left behind him in the carriage.

BOSTON.

— Dr. A. G. Griffin resigned his appointment of port physician, October 1st, to enter private practice. Dr. Griffin succeeded Dr. A. B. Heath as port physician in 1883, on the transfer of the latter gentleman to the superintendence of the Marcella Street Home. He had been assistant port physician for a year or more. Dr. Charles H. Cogswell has been promoted to fill the vacancy.

NEW YORK.

— The inauguration of the fine new buildings of the College of Physicians and Surgeons, the gifts of the Vanderbilt family, took place on the 29th of September, in the presence of a distinguished company. On this occasion Dr. John C. Dalton, President of the College, gave an historical sketch of the institution, and in speaking of its present prosperity paid a warm tribute to the generous benefactors by whose liberality such satisfactory accommodations have been provided for its work. Mr. Joseph H. Choate, of the Board of Trustees, was to have delivered the inaugural address, but as he was prevented from being present by illness in his family, his place was taken by Dr. William H. Draper, who also presented a number of memorial busts. The first of these was a fine bronze of the late William H. Vanderbilt, the gift of the Trustees and Faculty, for which Mr. Vanderbilt had been sitting on the day that he died. It is by the eminent sculptor, J. Q. A. Ward, and has been placed in the main hall at the entrance of the College building. The other busts were of the late Drs. Hosack and Mitchell, and of President John C. Dalton.

In the evening, in honor of the event, the alumni of the College had a banquet and jubilee celebration at Delmonico's. Dr. C. R. Agnew was toast-master, and after some remarks by the President, Dr. Dalton, Mr. Chauncy M. Depew responded for "Our Benefactors" in his usual happy vein. In the course of his speech he said: "No one could have attended the ceremonies this afternoon, heard the admirable addresses, looked into the faces of the alumni, and joined in the enthusiasm and applause, without breathing the university atmosphere and feeling like an alumnus of your college. Every man of middle age whose family physician is one of your graduates, has attested in crucial tests his devotion to the college. He has time and again shed his life-blood in serene confidence in your practitioners and their theories. He has time and again swallowed the most virulent of mineral and vegetable poisons to prove his loyalty, and his life has been at your service whenever you chose to take it. In England, this summer, I found that the medical theory of the hour was that all the ills that flesh is heir to come from eating and drink-

ing, and that the only panacea for perfect health is to give them up. In view of my public duties during the banquet season, I have rejected this advice, though obtained under the most expensive conditions from my London doctor. . . . When the College of Physicians and Surgeons reached 23d Street and halted, while the city swept on, you would have fallen behind, perhaps have been paralyzed, had not the Vanderbilt gift brought you abreast of the city's growth in wealth. For the first seventy-five years of our country's existence, our one need was money to develop mines, railroads, telegraphs, steam, electricity and inventions, and thus open up our unequalled natural resources. Fifty years ago there were not three ten-million-dollar men in the country, and not ten one-million-dollar men in New York. The man who had an income in excess of liberal living, for that reason alone had distinction, superiority, and social power; and the one ambition was for money. Now, rich men are so common that in itself wealth confers no power. The nation has more wealth than it needs for its development, and the millionaire is estimated by the use he makes of his money. Nobody asks him to divide his fortune, but everybody expects him to feel and act as if his possessions carried with them a trust. Their proper administration is his only opportunity to secure the good opinion of the community. If he simply schemes and hoards, he loses all that makes life worth the living — the respect of his neighbors here, the approval of his Maker hereafter. In the older States there are Colleges enough. The rich man who founds a new one to perpetuate his name, does no good and wastes his money. The endowment of colleges with age and traditions, in themselves a liberal education, helps us to obtain the best education and intellectual life. William H. Vanderbilt appreciated this, and selected for his benefaction the oldest medical college in the city."

Among the other speakers were Cornelius Vanderbilt; Daniel F. Gilman, President of Johns Hopkins University; the Rev. Dr. John Hall, Chancellor of the University of the City of New York; and Dr. William Pepper, Provost of the University of Pennsylvania. Letters of regret were read from Dr. Oliver Wendell Holmes; President Barnard, of Columbia College; President Dwight, of Yale University; Dr. Weir Mitchell, of Philadelphia; and Abram S. Hewitt, the Mayor of New York. In his letter, the Mayor said: "I am glad to say that the world more and more comes to the opinion that superfluous wealth is a public trust, and when this view is acted upon by those who have control of such wealth, we shall hear less of the sufferings of the poor, and of the antagonism which is believed to exist, but never can, between capital and labor."

On the same day as the inauguration exercises, the pavilion erected by Mrs. R. H. L. Townsend, at Bellevue Hospital, for the operative treatment of abdominal diseases in women, was formally presented to the city. The Rev. Henry S. Satterlee, in a few appropriate remarks, handed over the keys, in behalf of Mrs. Townsend, to the municipal authorities, represented by Commissioner Porter, of the Board of Charities and Correction, after which an informal reception and inspection of the new building followed. Six hundred patients of Bellevue Hospital were then treated to ice-cream and buns, in honor of the occasion.

— Dr. Smith, Health Officer of the Port, has announced that hereafter, the cargoes of vessels loaded with rags will be admitted without the delay and expense of disinfection, when they come with a clean bill of health from the sailing port. In order that they may escape this, it will be necessary that each invoice is accompanied by a certificate of the United States Consul at the sailing port that the rags were gathered in a country free from contagious or infectious disease.

— Of the eight cholera patients arriving in the *Alesia*, two have died at the hospital on Swinburne Island; and among the well passengers, who were transferred to Hoffman Island, there have been six cases and five deaths. Two new cases of the disease have developed.

— The position of Chief Inspector of Food and Chemical Analyses, on the Board of Health, has been abolished, and Dr. Cyrus Edson, who has held the post for a considerable time, has been made Chief Inspector of Contagious Diseases, in place of Dr. J. B. Taylor, resigned. Mr. Edward W. Martin, of the Columbia School of Mines, chemist to the department, is to take charge of the duties hitherto performed by Dr. Edson.

— Dr. Joseph D. Bryant, who has held the office of Surgeon-General of the State under both Governors, Cleveland and Hill, is one of the guests of President Cleveland on his Western and Southern trip.

Miscellany.

CURED PHARYNGEAL TUBERCULOSIS.

In a case of apparent tuberculosis of the posterior palatine folds, to which he was called in consultation several years ago, Dr. J. Solis-Cohen reports in the *Polyclinic*, September, 1887, that he advised thorough cleansing of the ulcers with a sponge, and energetic applications of powdered iodoform, but gave an unfavorable prognosis. To his surprise, the case was cured; but he has heretofore hesitated to record it, on the ground of possible mistaken diagnosis. It may be mentioned that there was not the slightest reason to suspect syphilis, that antisyphilitic constitutional treatment had failed to arrest the disease, and that there were all the objective and subjective indications deemed characteristic of primary tuberculosis.

Quite recently a similar case was brought to Dr. Cohen, in which emaciation to the extent of thirty pounds had ensued within a few weeks, as a result, chiefly, of difficulty in nourishment. The parts were cocainized, thoroughly scraped with a sharp spoon, and then energetically rubbed with a solution of lactic

acid, fifty per cent. This was repeated on several occasions with undiluted lactic acid until healthy granulation presented. Thorough cicatrization took place and the patient is for the time cured. Internally, one grain of iodoform and half a minim of creosote were administered in capsule thrice daily, after meals.

RESOLUTIONS ON THE LATE ALONZO CLARK, M.D.

At a meeting of the Board of Managers of the New York Society for the Relief of the Widows and Orphans of Medical Men, held September 21, 1887, Dr. Gouverneur M. Smith presiding, the death of Dr. Alonzo Clark, a late associate and benefactor having been announced, it was

Resolved, That this Board has heard with sincere sorrow of the death of Alonzo Clark, M.D., LL.D., and in view of his eminent service to the medical profession as scholar, instructor and counsellor, deems it fitting to place on record an expression of its appreciation of his eminent ability, singularly upright professional and private life, and of his zeal and ability as an investigator and lecturer.

Resolved, That the medical profession owes to him much of value in the advancement of medical science, while his ever loyal devotion to those needing his help and advice make his name one to be honored both by personal and professional friends.

Resolved, That, while there is in his death a sense of bereavement to those who knew him best, there is also the satisfaction of a long and honorable life, filled with results capable of accomplishing much of good to his fellowmen.

Resolved, That a copy of these Resolutions be sent to the family of Dr. Clark, and that they also be inscribed in full upon the minutes of this Board, and be published in the medical journals.

Willard Parker, M.D.,
John H. Hinton, M.D.,
Ellsworth Eliot, M.D., } *Committee.*

At a special meeting of the Board of Trustees of the College of Physicians and Surgeons, held on the twentieth day of September, 1887, the following resolutions were passed:

Whereas, We have been called upon to deplore the death of our late associate, Dr. Alonzo Clark, a former President of the College of Physicians and Surgeons, and for more than thirty years a distinguished professor in the institution; therefore,

Resolved, That we hereby record our eminent regard for the dignity and influence of Dr. Clark's personal character and our high appreciation of his attainments and distinction as a teacher.

Resolved, That the College of Physicians and Surgeons is largely indebted to Dr. Clark, as one of the most learned and skilful physicians of his time, for its high reputation as a school of medicine, and that it is both appropriate and gratifying for us, as trustees of the institution, to express our sense of the obligation. Also

Resolved, That we offer to the family of the deceased the assurance of our respectful sympathy in their deep affliction.

Resolved, That the foregoing resolutions be inscribed upon our minutes; that a copy of them signed by the President and Registrar, be transmitted to the family of the deceased; and that they be furnished for publication to such medical journals as the registrar may elect.

Willard Parker, M.D., *Secretary pro tem.*

Correspondence.

"AN M.D. IN NINE MONTHS." — REPLY.

Denver, Col., September 25, 1887.

Mr. Editor,— In the Journal of August 4, 1887, you kindly published a communication from me headed "An M.D. in Nine Months." I purposely left all names blank, but the Medical Department of the University of Vermont, through its instructor in surgery, has taken the case to itself, and thinks that I have cast "undeserved reflections upon them." Not wishing to be unjust, even by implication, and with a view of correcting any reflection, which may "seem" to be undeserved, that my original communication placed upon the Medical Department of the University of Vermont, I have to request of you an opportunity of publishing the following letter from my friend, Dr. Wheeler, which letter has been put by him in the shape in which he wishes it to appear in print, and is forwarded to you with his approval and consent.

Burlington, Vt., August 25, 1887.

Dear Dr. Fisk,— Your communication to the *Boston Medical and Surgical Journal*, of August 4th, entitled "An M.D. in Nine Months," has attracted my notice. A person who is not specially interested in medical colleges would not be likely to know which one you mean by the "University of ——," but your allusions are sufficiently definite to indicate to any one who is at all acquainted with the University of Vermont, that you refer to that institution. As I am one of its Board of Instructors, and as you charge us with being "lax in our requirements," and intimate that we are in the habit of grinding out doctors regardless of preparation or proficiency, I write in order to let you know all the facts in the case under consideration, some of which, I am sure, cannot have come to your knowledge. If you were a stranger to me I should not trouble you with this letter, but I know you, personally and professionally, too well to be willing that the University of Vermont should suffer undeservedly in your estimation, or that reflections upon its Medical Department which seems to me undeserved, should appear in print over your signature.

The Mr. X, to whom you refer, I take to be a gentleman by the name of ——, who came here from Denver. If this supposition is correct, either you are mistaken as to the length of time which he has spent in the study of medicine, or we were mistaken as to the genuineness of his credentials. He did come here, as you say, "armed with a card stating that he had attended *one* lecture course, and a certificate of having passed a satisfactory examination in materia medica and chemistry," but his armament also included a diploma which declared him qualified to practice pharmacy in the District of Columbia, and a certificate from Dr. ——, a reputable physician of Denver, stating that Mr. —— had "studied medicine *three full years*." I do not understand how a man who can present such credentials, can justly be said to have become an M.D. in nine months. Here is a qualified pharmacist (not a "drug clerk") who studies medicine three full years (not exactly the course pursued by the average "office boy,") and then attends lectures for nine months, at the end of which time he is allowed to go up for graduation, and on passing creditable examinations (as the gentleman in question did) takes his degree. This may be laxity as compared with a three years graded course, but there are few, if any, of the "two-courses-of-lectures-and-three-years-of-study" colleges (which still include the majority of our leading institutions), which do not allow graduates in pharmacy who have studied medicine three years, to come up to graduation at the end of their second course of lectures, even if both courses have been attended within the same twelvemonth. It is allowed here, as elsewhere, but such men do not often succeed in graduating. Three of them tried it here this year, but —— was the only one of the three who passed the examination.

The implication that the University of Vermont is the only college in which the second course of lectures could be taken within a twelvemonth of the first is erroneous. If a man with ——'s qualifications were to take his first course here, he could, in the following winter, take his second course and degree from any medical college which holds its regular session at that time of year and does not require a three years graded course.

With further reference to the matter of laxity, I would state that, of *seventy-nine* men who went up for graduation at the last Commencement of the Medical Department of the University of Vermont, only *fifty-three* succeeded in graduating. It does not strike me that a medical college which plucks *thirty-three per cent.* of its candidates for graduation can be very alarmingly "lax in its requirements." If there is another which can show as good a record, I should be glad to know it.

Sincerely yours, John B. Wheeler, M.D.
Instructor in Surgery, Medical Department Univ. of Vt.

Accepting Dr. Wheeler's statement, I will say that the certificate of Doctor —— and the additional certificate from the Board of Pharmacy, were sufficient evidence, so far as the University of Vermont was concerned, of Mr. ——'s preparatory training.

However, the laying so much emphasis upon them as qualifications for obtaining the degree of Doctor of Medicine, and slighting the fact, which Dr. Wheeler admits, of two courses of lectures taken in nine months, the second one being of only sixteen weeks duration, seems to me a little like letting the tail wag the dog.

Moreover, I am at a loss to understand what Dr. Wheeler means by saying that they allow "graduates in pharmacy, who have studied medicine three years, to come up for graduation at the end of their second course of lectures, even if both courses have been attended within the same twelvemonth," unless he also wishes it to be understood that a very liberal construction is to be placed upon the

"Requirements for Graduation," as they appear in their published "announcement."

Under that heading in their "Announcement" for 1887, I read:

"Candidates for the Degree of Doctor of Medicine, before presenting themselves for examination, must have attended two full courses of lectures of *twenty* weeks duration each, the latter at this College, and the time elapsing between the beginning of the first and the end of the second being at least *fifteen* months" (italics mine). Further on they state: "*Two full courses of lectures of at least twenty weeks each are absolutely required,*" and in a footnote they emphasize the fact that their lecture-course has been extended from sixteen to twenty weeks.

In spite of these published statements, the Faculty of the Medical Department of the University of Vermont have, in the case cited by Dr. Wheeler, graduated a man who attended both of his lecture-courses within the space of about nine months, the second course being only sixteen (not twenty) weeks in duration.

I would also remind Dr. Wheeler, in passing, that a man is not a "graduate in pharmacy," simply because he has a certificate from an Examining Board, of a State or District, entitling him to practice pharmacy; any more than he would be a "graduate in medicine" because he bore a certificate from a State Board of Medical Examiners.

Instead of laying so much stress on certificates, over which they have no control, it does seem as though this Faculty would have done better to have insisted upon the fulfilment of their "Requirements," over which they have absolute control.

It is no excuse that others do the same thing. The system is, I think, wrong, by whomsoever practised, and in all that I have written, my purpose has been simply to call attention to this process of quick parturition in medical education.

SAMUEL A. FISK, M.D.

Deaths reported 2,336: under five years of age 979; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, and fevers) 564, consumption 321, lung diseases 176, diarrhœal diseases 230, diphtheria and croup 149, typhoid fever 78, malarial fever 44, scarlet fever 18, whooping-cough 17, cerebro-spinal meningitis 16, erysipelas five, puerperal fever four, measles three. From malarial fevers, New Orleans 25, New York seven, Brooklyn six, Baltimore and District of Columbia three each, Nashville, and Charleston one each. From cerebro-spinal meningitis, New York five, Milwaukee three, Philadelphia, Pittsburgh, Cambridge, Fall River, Springfield, Somerville, Chelsea and Gloucester one each. From scarlet fever, Boston six, New York five, Philadelphia and Brooklyn two each, Pittsburgh and Nashville one each. From whooping-cough, Boston six, New York three, Philadelphia two, Brooklyn, Baltimore, Pittsburgh, Milwaukee, Charleston and Somerville one each. From erysipelas, New York and District of Columbia two each, Brooklyn one. From puerperal fever, New York, District of Columbia, New Bedford and Newton one each. From measles, New York two, Boston one.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending September 10th, the death-rate was 18.8. Deaths reported 3,333: infants under one year of age 1,072; acute diseases of the respiratory organs (London) 160; diarrhœa 469, scarlet fever 95, whooping-cough 83, fever 57, measles 32, diphtheria 28, small-pox (Sheffield three, Bristol one) four.

The death-rates ranged from 12.2 in Derby to 29.1 in Preston; Birmingham 16.9; Blackburn 22.8; Bradford 24.2; Hull 23.6; Leeds 17.4; Leicester 19.0; Liverpool 21.0; London 16.7; Manchester 25.2; Nottingham 20.2; Sheffield 19.8; Sunderland 19.3.

In Edinburgh 18.8; Glasgow 19.4; Dublin 27.9.

The meteorological record for the week ending September 24, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Sept. 24, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIESOF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 24, 1887, TO SEPTEMBER 30, 1887.

SMITH, A. K., lieutenant colonel and surgeon. Granted leave of absence for one month and fourteen days, to take effect upon his being relieved from duty at United States Military Academy. S. O. 223, A. G. O., September 24, 1887.

JOHNSON, R. W., captain and assistant surgeon. Granted leave of absence for twenty-one days, to be taken advantage of so that he will return to his station at latest by the middle of October, 1887. S. O. 204, Division of the Atlantic, September 23, 1887.

DUTZ, W. D., first lieutenant and assistant surgeon. Leave of absence extended one month. S. O. 223, A. G. O., September 24, 1887.

KNUDLER, WM. L., first lieutenant and assistant surgeon. Ordered to accompany Light Battery "F," 4th Artillery, from Fort Snelling, Minn., to the International Military Encampment at Chicago, Ill. S. O. 97, Department of Dakota, September 28, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 1, 1887.

MEANS, V. C. B., assistant surgeon. Ordered for examination preliminary to promotion.

DERR, E. Z., passed assistant surgeon. Detached from Navy Yard and to the "Nipsic."

ASHBRIDGE, RICHARD, passed assistant surgeon. Detached from Naval Academy, Annapolis, Md., and wait orders.

RUSSELL, A. H., passed assistant surgeon. Ordered to the Naval Academy, Annapolis, Md.

HERNDON, C. G., passed assistant surgeon. Detached from Naval Dispensary, Washington, D. C., and to the "Enterprise."

ARTHUR, GEORGE, passed assistant surgeon. Detached from the Museum of Hygiene, Washington, D. C., and to the Naval Dispensary.

GRIFFITHS, S. H., passed assistant surgeon. Ordered to the Museum of Hygiene, Washington, D. C.

SPEAR, J. C., medical inspector. Leave of absence granted until July 1, 1888, with permission to leave the United States.

SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. — THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, October 12th, at 7.45 o'clock. Papers: Dr. W. Everett Smith, "A Case of Poisoning from Arsenical Wall-paper." Dr. F. W. Stuart, "A Case of so-called 'Vicarious Menstruation.'" Members having specimens or other objects of interest to the profession, are requested to present them at this meeting.

ALBERT N. BLODGETT, M.D., *Secretary.*
F. I. KNIGHT, M.D., *Chairman.*

THE VERMONT STATE MEDICAL SOCIETY. — The Seventy-Fourth Annual Meeting of the Vermont State Medical Society will be held in the new Court-Room, State House, Montpelier, Vt., Thursday and Friday, October 13 and 14, 1887.

DEATHS.

Died in Lynn, Mass., September 28, 1887, John Ambrose McArthur, M.D., M.M.S.S., aged fifty-seven years.

Died in Hanover, Mass., September 29, 1887, John Odoway French, M.D., M.M.S.S.

RESOLUTIONS ON THE LATE DR. JOSEPH C. HUTCHINSON.

At a meeting of the Medical Staff of the Brooklyn Hospital, September 24, 1887, the following minute was adopted.

The long and active connection of our friend and associate, the late Dr. Jos. C. Hutchinson, with the Brooklyn Hospital, was characterized by earnest and unfaltering devotion to its interests. His preeminent professional skill, his large and varied experience, his conservative and accurate judgment, his genial manner and the inspiration of his native kindness and Christian manhood were ever ready for his professional associates as well as for those who sought the shelter of this institution for help, and were ever intent on all suggestions that served to keep the Brooklyn Hospital first and most liberal among the charitable institutions of the city.

Contributing as he did by his dignified presence and his many graceful accomplishments to the adornment and advantage of the enterprise, culture and benevolence of the city, the Brooklyn Hospital was nearer to his heart than any other interest, and to it were given his utmost care and the best of his gifts.

D. E. KISSANE, M.D., *President.*
ARTHUR R. PAINE, M.D., *Secretary.*

BOOKS AND PAMPHLETS RECEIVED.

INJURIES OF AND OPERATIONS UPON THE KIDNEY.[1]

BY EDWARD O. OTIS, M.D.

THE heart, lungs and kidney have been aptly called the three legs of the human tripod. Destroy or impair the integrity of any one of these three, and the vessel totters or is broken. Consequently, whatever interferes with the proper physiological function of these organs, be it disease or injury, must always be of the highest interest to the practitioner. When this interference comes from an injury or can be remedied by surgical device, the interest and attention of the surgeon is at once engaged. Of these three organs, up to the present time, with one or two exceptions in favor of the lungs, surgery has had only to do with the kidneys, and that of comparatively recent date.

I propose first to speak of injuries of the kidney, and secondly of operations upon it.

The kidneys, although so snugly and deeply ensconced in the body, are in that part of it which is naturally exposed to many dangers. Vehicles, car buffers and the like are about the right height to strike that portion of the body containing these organs, and their injury is no uncommon thing. Falls, compression between two unyielding bodies, blows, a falling mass, are generally the causes which produce the accident. Muscular strain may do it, and I have seen a comparatively light blow from a boxing glove produce one of the most characteristic signs of the injury, hæmaturia. The injury may be slight or severe; a simple contusion or bruise, or a multiple laceration. It may be subcutaneous, or communicating with an open wound. The peritoneum may or may not be involved. All parts of the kidney have been torn and lacerated; the most dangerous portion to be injured is the pelvis with the renal vessels.

The diagnosis of a subparietal injury can generally be pretty surely determined, but not always, as one of the cases which will be cited later testifies. We have as signs, the nature and circumstances of the accident; pain, more or less intense over the injured kidney; hæmaturia generally; retention of urine and retracted testicle sometimes; a tumor in the loin, dull on percussion, rarely occurs; and if the injury is a severe one there are the ordinary signs of shock and collapse. Of course there are many variations and combinations of these symptoms, and, as I have said, all or nearly all, may be absent. The prognosis, of course, depends upon the severity of the accident, and the amount of injury the kidney has sustained. If a simple contusion or bruise, as illustrated by the first case I shall presently give, the symptoms soon disappear and the patient is well. In lacerations, where the kidney is ruptured or crushed, the case is different, but even here authorities agree with Mr. Harrison, who says that "lacerations of the kidney is a lesion more frequently recovered from than any corresponding one of an internal organ."

Maas[2] gives an interesting series of experiments upon animals where the kidney was artificially ruptured or incised, and the number of recoveries are noteworthy.

By incision into the kidney no fatal result ensued. In certain cases where he severely ruptured the kidney, atrophy of the injured organ followed, and the remaining kidney performed the functions of both. In other cases cicatrization without subsequent symptoms followed: and in still others hydronephrosis and abscess resulted with necrosis of a great part of the kidney substance. In these experiments the most prominent symptom of rupture was hæmaturia. Maas[3] has also collected seventy-one cases of kidney injury, of which thirty-seven recovered and thirty-four succumbed, but of these thirty-four he says in only sixteen is the injury itself to be looked upon as sufficient cause of death. Bloch[4] records forty cases with twenty-three deaths; and Simon[5] ten, with seven deaths. I have collected twenty-seven cases (1879 to 1887) with eleven recoveries and sixteen deaths. Adding these twenty-seven cases to Maas' seventy-one [Maas probably included the cases of Bloch and Simon in his number,] we have ninety-eight cases with fifty deaths or a mortality of 51.02 per cent. (for subcutaneous injuries.)

A fatal result in an injury of the kidney may be caused by hæmorrhage, either primary or secondary, peritonitis, suppuration, abscess, and concomitant lesions of other organs. Maas in his cases found primary hæmorrhage as a cause of death relatively seldom. The treatment of the more severe cases — laceration and rupture — demand particularly our attention, for the question of surgical interference may come up. The cases of little gravity get well of themselves, with rest and expectant treatment.

Knowing, then, that the crush, blow, or fall over the kidney was a severe one; having profuse hæmaturia, intense pain in the loins, symptoms of collapse and the general signs of severe hæmorrhage; we can feel sure that we have to do with a ruptured or lacerated kidney, which may involve both the renal vessels and the peritoneum. What is to be done? The first thing, obviously, is to arrest the hæmorrhage, and without operative interference only indirect means can be used to accomplish this. Of the first importance is perfect and prolonged rest in bed; a disregard of this cardinal principle was followed with disastrous results in one of the cases reported, as you will see. The best external application is an ice-bag. Morphia subcutaneously or opium per anum must be given to alleviate pain and restlessness. Then comes the internal administration of astringents, and I should doubt if any of them do much good. They are ergot, tannin, gallic acid, acetate of lead, iron, matico, hydrastis, hamamelis, rhus aromatica, and others. The food should be liquid like milk and ice, and no stimulants should be given. Intestinal and gastric activity are to be reduced to a minimum. Catheterization may and probably will be required, and if the bladder is filled with clots, Mr. Morris suggests breaking them up with a lithotrite. The plan suggested by Dr. F. N. Otis[6] for dissolving clots in the bladder, by injecting into it a pepsin solution (a drachm of pepsin to two or three ounces of water), seems to me to be worthy of trial. Cystotomy may have to be performed to give exit to

the clots, as was done in a case of Mr. Rawdon's, reported by Mr. Morris.[7]

If, in spite of these means, the hæmaturia continues, and an increasing anæmia and collapse, accompanied perhaps with dulness and swelling in the loin, indicates that the hæmorrhage is still active, and a probability that the pelvis of the kidney has been involved, the only resource left is surgical interference. Simon's[8] points, which seem sufficient for an operation, are *strong collapse* and *swelling* in the region of the injured kidney.

This should be either an abdominal or lumbar incision; the latter is the operation to be at first thought of and done, and only in case one fails in this way to reach and tie the source of the hæmorrhage, or there are clots in the peritoneal cavity — the peritoneum having been torn — is abdominal section to be considered. A previous lumbar incision in no way prejudices a later abdominal one, so far as I can see. Moreover, the operation should be done, as Mr. Reeves[9] says, "before the patient is too weakened by hæmorrhage, and before septic phenomena have been allowed to develop."

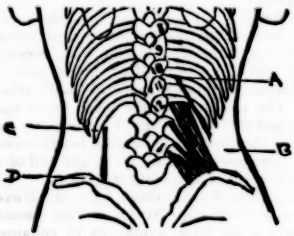

FIG. 1.

For injuries, the vertical incision (Fig. 1, C D), seems the most natural one, over the swelling if it exists, if not, from just below the twelfth rib to the crest of the ilium, along the external border of the quadratus lumborum muscle, or about three inches from the spine. If more room is desired, a second incision can be made from near the top of the vertical one outwards, about one-half an inch below the twelfth rib;

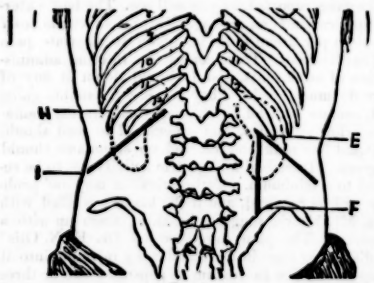

FIG. 2.

the whole incision will then be in the form of an inverted L (Fig. 2, E F). The ribs can also be strongly raised by retraction. The oblique incision, as in nephrotomy, is also equally good. The kidney, or what remains of it, having been reached, all clots, effused blood, and debris are to be removed, and the cavity thoroughly cleaned with an antiseptic fluid. The source of hæmorrhage is to be sought for and ligated. In cases of such serious gravity as to call for an operation, the pelvis of the kidney will probably be broken into and the renal vessels injured. These with the ureter should be ligated and the renal remnants removed; a nephrectomy done, which procedure receives the sanction of both Mr. Reeves[10] and Mr. Morris.[11] "Nephrectomy will in future," says the latter, "be probably adopted as giving the best prospect for recovery." That it has been done many times up to the present date, for wounds and lacerations, I find no evidence, and can only refer to five cases cited by Dr. Weir[12] in which it was done, and successfully so in three.

If the hæmorrhage has been stayed, an immediate operation, at least, is not indicated, but there are other dangers to be guarded against. Peritonitis is one, which, if it occurs, is to be treated in the usual way; or, knowing that it is of traumatic origin, abdominal section may properly be thought of. Extravasation, suppuration, and pyonephrosis are other late dangers, indicated by general constitutional symptoms, fever, rigors, etc., and often dulness and a tumor in the loin. All of these three last conditions call for lumbar incision and drainage. "If the kidney, by suppuration, is structurally destroyed, it is to be removed."[13] If the symptoms do not give clear evidence of fluid beneath, aspiration can first be resorted to. Septic decomposition in the bladder is still another danger, and, for its relief, washing out the organ with antiseptic solutions is required, or even cystotomy.

Compound fractures or injuries of the kidney are caused by firearms and penetrating instruments. They are rare in civil life. There are two symptoms which, if present, are pathognomonic of a wound of the kidney — hæmaturia and escape of urine from the wound. Of course, there are cases in which the evidences of an injury of the kidney are not clear, and only accumulate later.

The dangers are the same as in subparietal injuries, and are to be combatted in the same way. An operation may be demanded, as in the other class of cases, and under similar circumstances. In the seventy-eight cases reported in the medical and surgical history of the War, twenty-six recovered. Nephrectomy or nephrotomy was not done in any case; probably more cases would have been saved if they had been. "If life be threatened by hæmorrhage or suppuration, the kidney ought to be removed by lumbar nephrectomy."[14] The external wound should be treated on general antiseptic principles.

I am aware that I have only given, in relation to injuries of the kidney, about what are the opinions and experience of all modern surgeons. The one point I wish to emphasize is the recourse to an operation — lumbar or abdominal incision, with nephrotomy or nephrectomy, and ligature of the ruptured vessels, when other means fail to control the hæmorrhage — and the doing of this just as soon as it is evident that

the bleeding is jeopardizing the life of the patient. Also, if the danger from primary hæmorrhage is past, a later operation of the same kind for suppuration, extravasation, or pyonephrosis.

In concluding this part of my paper, I can, perhaps, make it more vivid by giving a few illustrative cases from among those I have collected.

ILLUSTRATIVE CASES.

Case I. My own. A student was thrown violently down in a game of foot-ball. Severe pain in the lumbar region, over the kidney, and hæmaturia followed; also some difficulty in micturition. Rest in bed, poultice over the loin, and ergotin were prescribed. The hæmaturia ceased in one or two days. He grew rapidly better, and in a week or ten days was up and about. Several weeks after the accident, he reported himself as feeling perfectly well. This illustrates one of the lighter forms of injury, and might, perhaps, be called a bruise of the kidney.

Case II. Reported by W. Macfie Campbell.[15] Supposed rupture of the kidney. A boy of fourteen years, in leaping over a hedge, struck first on his feet, and then fell and rolled over on his left side. He picked himself up, and walked some distance. There followed shock, intense pain over the left kidney, and more or less profuse hæmaturia, which disappeared in a few days. Later, some rise of temperature for a few days. The treatment was perfect rest, liquid diet, gallic acid, and opium, with ice over the injured kidney. The ice was the only thing which relieved the intense pain, which returned as soon as it was removed. In a microscopic examination of the urine, blood, casts and traces of broken tubules were found.

The pain disappeared in two days, and he was sitting up in seven days. He became and remained entirely well. The author bases his diagnosis of rupture upon the immediate violence of the symptoms, the amount of blood lost, and the presence of blood casts and broken tubules. He further adds that "the differential diagnosis between rupture and contusion is by no means easy, nor for treatment is it essential."

Case III. Reported by W. Y. Eales.[16] Crush and rupture of the kidney. The accident was caused by a mass of coal falling upon the patient. The injury was followed by collapse, intense pain in the right lumbar region on deep breath, and hæmaturia. Death occurred sixty hours after the accident, from anæmia and shock. On autopsy, a large quantity of blood was found in the peritoneal cavity, and, behind the right kidney, was an enormous amount of blood-clots and effused blood. The kidney itself was, in its upper half, smashed to a pulp, and, in its lower half, was a small, deep, jagged wound. No wound of the trunk artery or vein was detected. The ureter was blocked by blood-clots.

One thinks of an operation in a case like this as soon as the hæmorrhage was seen to be alarming, but, in the light of the autopsy, only an abdominal section would probably have offered any chance of success.

Case IV. Reported by W. Jas. Spence.[17] Rupture of the kidney; death on the forty-seventh day. The patient was struck in the right flank by the revolving handle of a travelling crane, and knocked down a cutting some sixteen or seventeen feet deep. Collapse ensued, with pain and hæmaturia. An ice-bag was applied to the loin, and opium given. The hæmaturia continued more or less profusely for eight days, when it subsided under large doses of iron. On the nineteenth and twentieth days after the accident, the patient sat up for two or three hours each day. On the twenty-first day hæmaturia recurred, and, with two days intermission, continued until he died of exhaustion, forty-seven days after the accident. Lead, ergot, turpentine, and other remedies were tried without avail.

At the autopsy, a rent was found in the medullary substance at the upper part of the right kidney. This rent was filled with a decolorized and partly-organized clot. The pelvis of the kidney, the ureter, and bladder, were distended with blood-clots.

Here, again, was not an operation indicated when the secondary hæmorrhage occurred, and all other means to stay it had failed? Incidentally, the case shows the disastrous effect of movement, for all was going well when the patient sat up.

Case V. Reported by T. W. Stokes.[18] The patient was crushed between the buffers of two cars, and was supposed to have sustained a laceration of the liver, no symptoms pointing to an injury of any other organ. The urine was drawn, and found clear. Pain not very intense, and chiefly confined to the region of the liver. Death occurred four days after the accident. At the autopsy, besides extensive injury to the liver, the right kidney was found to be extensively torn, the lacerations running transversely, and extending almost to the sinus, but not in it, which, the author thinks, accounts for the absence of hæmaturia. The kidney tear was completely sealed up and in process of healing, its edges being glued together by lymph. The immediate cause of death was secondary hæmorrhage, probably from one of the lacerations of the liver.

The case is interesting, as showing the process of repair in a badly-lacerated kidney, and the absence of almost all the signs of a rupture of that organ. The author's reason for the absence of hæmaturia was probably the correct one.

Case VI. Reported by M. Maunoury.[19] A carter was crushed between his cart and a post. The day after the accident, he noticed that his urine was bloody, but he paid no attention to it, and in a few days resumed his work. Hæmaturia, however, continued, and finally retention followed. He applied to a pharmacist, who catheterized him. Later, fever appeared, and other serious symptoms, and he entered a hospital. Here evidences of extensive suppuration were found, and a tumor detected in the left lumbar region. Aspiration showing pus, a lumbar incision was made, giving exit to almost a quart of pus, mixed with fragments of renal tissue, the total mass of fragments weighing nearly two ounces. The vast cavity was washed out, and an antiseptic dressing applied. Healing was complete in about a month and a half.

It is marvellous that, with so serious a laceration as this evidently was, the symptoms, at the first, should have been of so little intensity.

OPERATIONS UPON THE KIDNEY.

Two cases occurring in my own practice, the one fatal, and the other full of suffering, have indelibly impressed upon my mind the importance of surgical interference in certain affections of the kidney, notably calculus and suppurative lesions, as affording the only

[19] Revue de Chirurgie (Paris), 1885, V, p. 418.

deliverance in otherwise hopeless cases. The one case was that of a young married man, who, for years, suffered from symptoms of renal calculus, enduring the most excruciating and convulsive pain of renal colic, and for which he vacillated between opium-eating and rum-drinking, becoming a curse to himself and his unhappy family. The other case [20] was also that of a young man just beginning a professional career, from which he had much to hope, afflicted with a suppurative affection of one kidney. After dragging out a wretched existence for two years, he died of pyæmia, and the autopsy revealed an enormously dilated, pus-secreting sac in the place of the kidney. Both of these lives, I believe, might have been restored to usefulness and comparative health through the intervention of surgery.

To Simon, of Heidelberg, and Morris, of London, the surgical profession is indebted for firmly establishing the operations of nephro-lithotomy and nephrectomy, nephro-lithotomy having been first performed by the latter in 1880, and nephrectomy by the former in 1869.

Besides these two operations, with which the remainder of this paper will be chiefly concerned, we have nephrotomy, nephrorraphy, paracentesis, and what Mr. Lucas [21] makes a distinct operation, exploration of the kidney, which is but a part of nephro-lithotomy.

Within the last few years, recorded cases of operations upon the kidney have been rapidly multiplying, and the literature upon the subject is becoming voluminous. Gross's [22] paper, based upon an analysis of nearly four hundred and fifty cases of all kinds, embracing all he could collect up to May 15, 1885, is well known to you.

I have collected, of cases recorded since that date, sixty-eight operations of all kinds, as follows: [23]

Nephrectomies, 28 with 6 deaths, 21.42%. Of these 18 were lumbar with 2 deaths, 11.11%; and 8 abdominal, with 4 deaths, 50%; the incision in two cases was unknown. Nephrotomies, 13 with 4 deaths, 30.77%. Nephro-lithotomies, 21 with 2 deaths, 9.52%. Exploration, 2 with no deaths. Nephrorraphy, 4 with no deaths.

Of these sixty-eight cases, thirty-two were for calculus, in which nephrotomy was done nine times, with one death; nephrectomy twice, with one death; and nephro-lithotomy twenty-one times, with two deaths. I have added these cases to Dr. Gross's, and give a synopsis of the result.

The indications and technique of nephro-lithotomy and nephrectomy have been carefully discussed by surgeons of all countries, and, at the present time, the tendency is toward a greater precision in diagnosis, and earlier surgical interference.

With regard to the indications for nephrectomy, for a broad rule, Simon's [24] is a good one: that when a reasonable certainty exists that one kidney is healthy, and the other is the seat of advanced and irremediable disease, its extirpation is justifiable.

SYNOPSIS OF GROSS'S CASES WITH SIXTY-EIGHT ADDITIONAL ONES ADDED THERETO, COLLECTED SINCE MAY 15TH, 1885, THE DATE OF HIS PAPER.

	No. of cases	Recovered	Died	Per cent. died
Nephrectomies both lumbar and abdominal for all causes	261	153	110	42.14
Nephro-lithotomy	42	38	4	9.52
Nephrotomy (lumbar)	116	89	27	23.28
Nephorraphy	22	21	1	4.54
Exploration	31	31	0	0
SUPPURATIVE LESIONS FROM ALL CAUSES.				
Nephrectomy	90	55	35	38.88
Nephrotomy	104	79	25	24.04
INCISIONS.				
Lumbar	129	86	43	33.33
Abdominal	128	63	65	50.78

Nephrectomy, says Wagner,[25] is urgently indicated in cases in which the renal lesion directly threatens life. As, for instance, in cases of severe injury of the organ, and malignant disease. In suppurative affections, if the disease be progressive, has caused emaciation and hectic fever, and is likely to be associated with general amyloid degeneration. Braun [26] adds cases of fistula of the ureter which cannot be healed, and injuries of the kidney, where an open wound permits a clear recognition of the injury. He finds, further, that nephrectomy for malignant tumors give bad results, while, on the contrary, the results from this operation for pyelitis and pyelo-nephrosis are remarkably good, he having obtained twenty-three complete recoveries from thirty-eight operations. In hydro-nephrosis, he is in doubt whether a fistula or extirpation is the better procedure. Gross, and many others, hold that nephrectomy should not be resorted to as a primary operation in suppurative lesions, but only after a previous nephrotomy. No hard and fast rule can be laid down, it seems to me, but the surgeon must be governed in his decision very much by the condition of the case and patient. One thing is certain, that nephrectomy is being more frequently done every year; and Tillaux's [27] opinion, that it is an operation which ought to be reserved for very exceptional cases, is receiving a less rigid interpretation.

It is, of course, a very serious matter to leave the patient with only one kidney, ignorant as the operator is of the exact condition of that one, or, in fact, if it exists, though this last risk is a small one, for out of eight thousand and sixty-six post-mortem cases, according to Mr. Morris, there were but two instances of congenital absence, and one only of congenital atrophy of the kidney. That a single kidney is capable of eliminating sufficient urine for the maintenance of health, is sufficiently well established: that it so increases its functional powers as to perform the full amount of work formerly performed by the two kidneys, seems to me to be extremely doubtful. At

all events, the man with one kidney is very like the showman with his head in the lion's mouth, who calls out: "Is he wagging his tail? for, if so, it is all over with me." If this one kidney is attacked with disease, it is likely to be all over with him.

(To be continued.)

THE THERAPEUTIC VALUE OF MALT.

BY CHARLES W. TOWNSEND, M.D.

ONE of the fashionable remedies of the present day is the extract of malt in the form of one of its numerous preparations. Its valuable properties are generally considered to be: first, the concentrated nutriment it contains; second, the digestive power it possesses owing to the presence of diastase. From its first property it is indicated in cases of malnutrition where a concentrated food is desired, and one that is in a condition to be directly absorbed. From its second property it would seem to be indicated in cases of starchy dyspepsia, where some artificial ferment is needed to aid or supply the place of the natural ones in digesting starch. That the diastase found in malt and in good malt extracts is capable of digesting starch at the temperature of the body in a test-tube is a fact easily confirmed. Will malt do this in the alimentary canal? If not, malt given after a meal, as is usually prescribed, is of value only from its contained nutriment and its diastatic power is simply wasted. In the test-tube experiment malt and starch are brought in contact in a watery medium and are raised to the temperature of the body, but in the stomach the malt would have to act on the starch in the presence not only of the other solid and fluid ingesta and the products of their digestion and decomposition, but also in the presence of the gastric juice. Now it may be that the diastase is either destroyed or its action so hindered by the acids produced by fermentation from the ingesta, or by the hydrochloric acid of the gastric juice, or by that and pepsin combined that it is unable to act on the starch. To determine this point the following experiments were performed: First, the effect of various percentages of hydrochloric acid on the diastatic power of malt. Second, the effect of pepsin alone and of pepsin combined with hydro-chloric acid on this power. Third, the diastatic power of malt in the stomach of the living animal.

To test the action of malt in the presence of hydrochloric acid, a water bath was used, kept at a temperature between 99° and 104° F. by an alcohol lamp. In each experiment one ounce of clear starch paste, made by boiling fifteen grains of starch in one ounce of water, was used, and thirty minims of a liquid extract of malt. This proportion of malt to starch was larger than was really needed to convert the starch to sugar, but saved time and made the results of the experiments more satisfactory. Chemically pure hydrochloric acid was used, and the percentages calculated are those of the anhydrous acid. The paste, paste and water or paste and acid solution were first put in the vessel in the water-bath, the malt was then added, and the solution tested every few minutes by placing a drop in one of a series of test-tubes containing a solution of tincture of iodine, in the proportion of two drops to the ounce of water. The experiments were continued from twenty-five to forty-five minutes, and most of them were verified by repetition.

No.	Paste	Water	Percentage of HCl.	Malt	Result
1	1 oz.	....	....	30 m.	Paste liquefied in two minutes, all changed to sugar in ten minutes
2	1 oz.	6 oz.	....	30 m.	In one minute starch mostly changed to sugar as shown by purple tint with iodine; all changed to sugar in seven minutes
3	1 oz.	....	.2 or 1-5 per cent.	30 m.	Starch as abundant at end of twenty-fifth minute as end of first minute
4	1 oz.	6 oz.	.03, about 1-33	30 m.	Starch as abundant at end of twenty-fifth minute as end of first minute
5	1 oz.	6 oz.	.015, about 1-66	30 m	Experiments continued for forty-five minutes and starch still found as abundantly as at first
6	1 oz.	6 oz.	.0111, about 1-90	30 m.	Experiments continued for forty-five minutes and starch still found as abundantly as at first
7	1 oz.	6 oz.	.00740, about 1-135	30 m.	In four minutes starch partly changed as shown by purple tint with iodine but not till thirty minutes was it all changed to sugar
8	1 oz.	6 oz.	.00565, about 1-177	30 m.	The purple tint with iodine showed itself in two minutes; starch all changed to sugar in thirty minutes
9	1 oz.	6 oz.	.00370, about 1-270	30 m.	Changed to purple with iodine in one minute; all changed to sugar in seven minutes; results same as that of experiment two

The gastric juice, according to Foster,[1] contains two per cent of free hydro-chloric acid. The contents of the stomach after a meal has, of course, a less acidity than this from the dilution of the juice with food and drink, but, as reference to the table will show, .011 per cent. of free acid was sufficient to stop the diastatic power of malt entirely; .00565 per cent. of free acid checked the action of the malt to a slight extent, but .00370 per cent., an extreme dilution, had no effect whatever. Now .0111 per cent., the minimum percentage according to these experiments necessary to entirely check the action of the diastase of malt, would be about the percentage of acid in a stomach containing one ounce of gastric juice and nineteen ounces of other fluid, and it is probable that the percentage of acid in the stomach is usually much greater. The following calculations show this to be the case: The amount of gastric juice secreted in twenty-four hours, according to Bidder and Schmidt,[2] is 6,400 grammes or about fourteen pounds, and even supposing that it is secreted equally at all times, whether food is in the stomach or not, this would give one-and-one-sixth pounds secreted during the two hours of stomach digestion following a meal. Flint[3] calculates that as two ounces of gastric juice have been found to be secreted in response to stimulation in ten minutes, twenty-four ounces, or a pound and a half, avoirdupois, are secreted in the two hours of gastric digestion. Now, in order to reduce the normal .2 per cent. strength of hydrochloric acid in the one-and-one-fourth pounds, we will say, of gastric juice to a .011 per cent. solution, the minimum amount of acid needed to stop entirely the action of diastase, it would be necessary to ingest about twenty-two pounds of fluid at that meal. Of course, this amount of fluid is not taken at one meal, at least by invalids for whom malt

[1] Text-book of Physiology, New York, 1880, p. 246.
[2] A. Flint, Jr. Physiology of Man, Vol. II.
[3] Ibid.

is intended, and, therefore, the percentage of acid in the contents of the stomach must be much greater than the minimum percentage needed to check the action of diastase. In fact, the amount of acid needed for this purpose is so small that great diminution in the amount and acidity of the gastric juice would be possible, and still suffice to render the diastase worthless.

But, it may be asked, will not the malt be able to act on the starch when it has passed from the acid stomach to the alkaline duodenum? To determine this point and to imitate this process in the living animal, experiment No. 6 was repeated, but at the end of thirty minutes sufficient hydrate of potash was added to neutralize the hydrochloric acid. At the end of twenty-five minutes after neutralization a deep blue percipitate was still caused by the addition of a drop of the solution containing the malt to the test solution of iodine. In a second experiment the same solution in the water was made slightly alkaline at the end of thirty minutes, but the starch remained unchanged after fifteen minutes more, when the experiment was discontinued.

From these experiments it seems rational to infer that the diastatic power of malt is permanently destroyed by the presence of hydrochloric acid in not larger quantity than is found in the stomach, and therefore that malt given by the mouth is of no value as a digestive.

The action of diastase was found not to be noticeably affected by the presence of pepsin alone, or of pepsin and of as much hydrochloric acid as had previously been found to have no effect on this action. This is to be expected, for pepsin acts best in a two per cent. hydrochloric acid solution, and refuses to act in a neutral or very faintly acid solution, and it is probable that in a stronger acid solution, where the acid alone is sufficient to arrest the action of the diastase, the presence of pepsin would assist by digesting this ferment.

As confirming the results of these experiments in which a water-bath was used as an artificial stomach, the following, in which living stomachs were used, are of interest.

A litter of five kittens about one month old were chosen, and each one was given by the mouth some milk containing a measured amount of boiled starch, followed immediately by some more milk containing fluid extract of malt. More malt was given than would have been sufficient to digest the starch at the temperature of the body in a test-tube in seven minutes. The kittens were killed by ether ten, fifteen, twenty, thirty and sixty minutes respectively after their meal of malt, and the contents of the stomachs turned into vessels and tested by the iodine test for starch. In all cases starch was found present in large quantities.

Having considered this diastatic property and shown, it seems to me, conclusively that it is valueless in the ordinary method of administration of malt, the direct nutritive value of malt remains to be considered. That this is great is abundantly proven clinically, cases of malnutrition improving under its use in the same way as from the use of cod-liver oil. Malt, however, is often preferable to cod-liver oil, as it is free from disagreeable odor and taste, is not so liable to loosen the bowels as the oil is so apt to do in infants and young children, and is in many cases much more easily assimilated. It is hardly possible to make a comparison of the nutritive values of malt and cod-liver oil by an examination of their constituents, for the latter is composed almost wholly of various fatty acids,— oleic, palmitic and stearic,— combined with glycerine, with the addition of biliary principles and small amounts of iodine, phosphorus, lime, magnesia, and iron, and phosphoric and sulphuric acids, while the former consists chiefly of carbo-hydrates,— glucose and dextrine,— with a small amount of nitrogenous substances, among which is diastase, and of inorganic substances, chiefly phosphates of potash and magnesia, with small quantities of lime, soda and iron, and sulphuric and silicic acids.

With malt liquors and Liebig's food or malted wheat, however, a comparison can more easily be made, and the nutritive value of both of these is well known. Beer is essentially a solution of malt in water with the addition of hops and of alcohol and carbonic dioxide, the two latter formed at the expense of some of the glucose. Alcohol adds, of course, to its nutritive value, but that the chief value resides in the malt is evident, when we consider that people who drink the light wines, which are equal in alcoholic strength to beer, do not display that rotundity of figure seen in the beer drinkers. Liebig's food is malted wheat and differs from barley malt only by not possessing diastase, and by being made from a different grain. The nutritive value of wheat is, however, superior to that of barley, as it is superior to that of most other grains, it being especially rich in nitrogenous substances, constituents in which barley is comparatively poor.

In the following table, the amount of nutriment in a glass of beer, a tablespoonful of fluid extract of malt and a tablespoonful of malted wheat has been calculated from analyses given by Payen [4] and Leeds.[5]

	Glass Beer (℥ vii).	Ext. Malt (℥ ss).	Malted Wheat (℥ ss).
Water	gr. 3636.480	gr. 53.928	gr. 12.000
Alcohol	172.860	3.816	....
Glucose and dextrine	158.976	148.728	205.656
Nitrogenous substances.	2.026	7.464	14.280
Inorganic salts	.706	2.784	3.536
Glycerine	....	22.248	(fat) .360
Lactic acid	....	3.816	....
Grains	3970.988	242.784	235.232

The small amount of alcohol in the malt extract is due to the presence of the tincture of hops. The above is interesting, as showing that a glass of beer and a tablespoonful of the malt are practically of the same nutritive value as far as the sugar is concerned, while the tablespoonful of malted wheat or Liebig's food contains one-third as much again of sugar; but the two latter are superior to beer in nitrogenous substances, the malt containing more than three times as much, and the Liebig's food more than seven times as much; and they are also superior to beer in the inorganic salts, the malt having nearly four times as much, while the Liebig's food has nearly five times as much. Beer, of course, contains alcohol in addition.

[4] Préces theorique et prat. des subst. aliment.
[5] Leeds. Phila. Med. News, July 21, 1883.

The superiority of the Liebig's food in nitrogenous substances and minerals makes it preferable to malt, if the diastatic power of the latter is to be disregarded, by taking it directly into the stomach.

By way of summary, it may be said that although malt by reason of its contained diastase is able to convert starch into sugar in a watery medium at the temperature of the body, it has no power over starch in the living stomach, owing to the presence of the gastric juice. Administered directly by the mouth, therefore, it is of use only on account of its contained nutriment, and is inferior in the amount of nitrogenous and inorganic principles to a food formed by the action of diastase on wheat, that is to say, to Liebig's food.

REPORT ON PROGRESS IN THERAPEUTICS.[1]

BY FRANCIS H. WILLIAMS, M.D.

NAPHTHALIN.

Naphthalin seems to be of special value as an intestinal antiseptic or germicide — being so sparingly soluble that much of it remains to act upon the intestines and their contents from the stomach to the rectum. Rossbach advises it in intestinal catarrh. Borelius reports cases of typhoid in which it seemed to relieve the abdominal symptoms. Its value is especially urged by Dr. L. Emmet Holt,[17] in a paper on the "Antiseptic Treatment of Summer Diarrhœa." His conclusions are: That summer diarrhœa has many remote causes, but the single immediate cause is putrefactive changes taking place in undigested food in the stomach and bowels, the products of these changes acting either as systemic poisons or locally irritating agents, causing catarrhal and inflammatory conditions in the intestines. The diarrhœa is, at the outset at least, salutary, and the use of astringents and opium is not only useless, but, in the beginning especially, may do positive harm by checking peristalsis and increasing decomposition. (Opium in many other forms of diarrhœa he regards of value.)

The indications to be fulfilled are: (1) Clear the bowels; (2) stop decomposition; (3) restore healthy action; (4) treat consequential lesions. To meet the first he recommends castor oil, the second, salicylate of sodium or naphthalin, the third and fourth, if present, call for various measures, but in the majority of cases castor oil and salicylate of sodium or naphthalin were alone necessary. He gives statistics of 300 cases treated by the old routine of opium and astringents preceded by castor oil, resulting in 50% cured, 27% improved; also of 81 cases treated during the past year with castor oil and salicylate of sodium, resulting in 84% cured, 7% improved; and of 44 cases treated with castor-oil and naphthalin, 67% were cured and 15% improved. Resorcin gave only 55% cured, 22% improved. He says of naphthalin, it is of latest introduction and seems likely to prove of very great value, perhaps the most valuable of all. He also reports seven cases of chronic dysentery and twenty-one cases of chronic diarrhœa, treated by naphthalin *alone*, with uniformly good results. Concerning the dose and administration: it may be given in powder, mixed with sugar and taken in wafers or capsules, the taste is not bad, but very persistent and strongly suggestive of tar.

In summer diarrhœa of children, he used from two to six grains, according to the age, (when he used salicylate of sodium he gave one to three grains) every two hours. If the child were not on the breast he withheld milk entirely, and with vomiting he withheld all food for twelve to twenty-four hours. In chronic diarrhœa, dysentery and typhoid he used large doses of naphthalin, sixty to ninety grains daily.

One point in regard to naphthalin requires investigation before its extensive use can be with perfect safety recommended. A note in the *Vienna Zeitschrift des Œsterreichs Apotheker Vereins*, 1887, xli, p. 38, states that in the Paris Academy of Medicine, Prof. Bouchard reported that animals to whom naphthalin was administered internally developed beginning cataract within twenty days or less, generally in both eyes simultaneously, and that the cataract process thus begun did not stop with discontinuance of the drug. The theory was advanced that the affinity of naphthalin for sulphur affected the globulin of the lens.[18] Doubtless the doses used were, for the animal, excessive, and very likely have no important bearing against the therapeutic use of the drug. Certainly no untoward effects are reported from its clinical use, except dark-colored urine and a single case of dysuria from large doses.

RESORCIN.

This drug is favorably reported in the treatment of cutaneous and gastric disorders. Dr. Edward Maclay[19] claims for it the antiseptic properties of carbolic acid without the irritant properties of that substance. A two per cent. solution is antiseptic, and irritating to the tissues. It seems to possess special advantages in the treatment of gastric and cutaneous disorders. Dr. Maclay reports two cases of gastric ulcer with immediate recovery under its use. In gastric catarrh not relieved by bismuth, soda, etc., recovery followed at once under treatment with resorcin. Intestinal catarrhs, chronic diarrhœa, etc., were in no way benefitted by resorcin, nor were the evacuations disinfected, constituting a marked contrast to the action of naphthalin, and suggesting a special field of action for each of these two drugs; naphthalin for intestinal disorders or wherever it is desirable to disinfect the intestinal canal or render antiseptic its contents; resorcin for the same purpose in the stomach and externally on sensitive tissues. Internally Dr. Maclay employs five-grain doses of resorcin three times a day, given in water with a little glycerine, or in chloroform-water. The taste is peculiar, but slight, and easily tolerated. Much larger doses have been employed, but are not advisable, thirty grains having caused febrile disturbance, and sixty grains marked toxic action, dizziness and collapse.

CORROSIVE SUBLIMATE.

The use of corrosive sublimate as an antiseptic has been on the accepted ground that in the weak solutions employed, while destructive to germs it is not dangerous to the patient. Some recent observations and cases would suggest considerable caution, at least, in its use. Fleischmann, of Prague, reports a fatal case of acute poisoning in a healthy primipara, from

[1] Concluded from page 333.

[17] Medical Record, January 15, 1887. Therap. Gaz., February, 1887, 108, March, 1887, 184.

[18] Australian Med. Gaz., April, 1887, 165.

[19] Lond. Med. Record, September 4, 1886. Therap. Gaz., 1886, 761.

two vaginal douches before labor, sublimate solution 1 : 2000 being used. Abdominal pain, rise of temperature, diarrhœa occurred an hour after the second injection, followed by nephritis, salivation, continued diarrhœa, and, after the birth of the child, death in coma on the ninth day following the douche. The pathological anatomical diagnosis from the autopsy was: Corrosive sublimate poisoning, acute nephritis, dysentery, stomatitis and pharyngitis in the stage of ulceration, parenchymatous degeneration of heart and liver, lobar and lobular pneumonia, bilateral, acute cystitis. Investigation showed that the patient had left her bed and worked about the ward after the douching; that all ordinary precautions were taken to secure the complete expulsion of the fluid from the vagina. It is suggested as possible that some of the fluid entered the uterus through the dilated os, and it is further stated that the patient had a slight diarrhœa before the douching.

Fleischmann calls attention to the danger attending the use of sublimate in puerperal patients with any lesion or disordered conditions of the bowels or kidneys, and quotes an eminent authority to the effect that the use of sublimate in obstetrics should be limited to disinfection of the hands, instruments and external genitalia.[20] An article by the Paris correspondent of the *British Medical Journal*, October 9, 1886,[21] is of interest in this connection. He calls attention to the frequency of intestinal lesions coming to the notice of medical men, especially those in obstetric practice, since the wide use of corrosive sublimate as an antiseptic, and refers to the experiments of Prévost,[22] indicating that visceral lesions may be produced by sublimate. M. M. Cherin and Roger experimented on animals with sublimate solution of 1 : 1000 to 1 : 4000, injected subcutaneously or intravenously, and obtained uniform intestinal lesions, varying with the dose, localized in the large intestine, and consisting of ecchymoses, hæmorrhage and ulceration, the principal lesion being hæmorrhage. Perforation did not occur. These experiments, however, indicated a dose of 0.24 as necessary to produce ulceration in a man weighing 60 K., while some clinical facts seemed to indicate the possibility that smaller doses might cause such a result in man. The experimenters did not deem the possibility of such an accident, however, sufficient to lead to the proscription of the use of sublimate as an antiseptic.

Maximilian Jolles and Erlangen give an elaborate demonstration of the identity of lesions and clinical history in sublimate poisoning and septic infection.[23] Gläser, of Hamburg, reports twenty-three cases of typhoid treated with corrosive sublimate with very bad results and no benefits. In diphtheria, on the other hand, Dr. Verner reports [24] seventeen cases with very good results, giving one-fourth to three-fourth grains daily.

The conclusions warranted, seem to be that corrosive sublimate is an efficient antiseptic, but best adapted to external use, suggesting caution in its use in obstetries for douching, especially with any disorder of bowels or kidneys, and throwing doubt on the possibility of safe disinfection of the blood or intestinal canal by internal administration in infective diseases.

SUBCUTANEOUS ANTISEPSIS.

Dr. Albin Meunier [25] advocates the treatment of many diseases due to micro-organisms by the subcutaneous administration of antiseptic, especially eucalyptol and iodoform in pure vaseline. The difficulty of disinfection of circulating blood without danger to the patient is great, and any successful solution of the problem will be most welcome, but it hardly seems that it is so much to come by the method of administration as by the agents used. (Mercury is already administered subcutaneously for syphilis by some practitioners, and with good results, it is claimed.)

ANTISEPSIS IN PHTHISIS.

The therapeutics of phthisis have had the usual addition of "new remedies," promising very much the same history as former numerous discoveries of a like nature. The recent work, however, is based on the germicide theory, and the problem already alluded to seems equally difficult here. Bergeons, of Lyons, advances the treatment by rectal injections of sulphuretted hydrogen. Prof. Kremianski, in a paper before the Moscow Medical Congress, advocates inhalations of atomized aniline, while intrapulmonary injections of iodoform preparations are supported by several observers.

Concerning Bergeon's treatment, Wyss, of Geneva,[26] calls in question first of all the theoretical ground-work, showing at least the non-establishment of any destructive action by the gas on the bacilli, with their persistence in the sputum of patients treated by the gas, while both abroad and in America hospitals are reporting fully as adversely as favorably in regard to clinical results.

The aniline treatment is newer, has fewer clinical observations for or against it, but has in its favor what sulphuretted hydrogen has not: that it is a substance destructive, even in very great dilution, to the tubercle bacillus of Koch. (It would be interesting to follow out the results of large doses of antifebrin in phthisis, since that drug is of the aniline series, in connection with this germicide action of aniline.)

Intrapulmonary injections of solutions of iodoform in oil of eucalyptus, constitutes part of the so-called "subcutaneous antisepsis" already mentioned. Some very good results are reported in gangrene of the lung and in disinfection of pulmonary cavities, but nothing definite toward the relief of the essential conditions of phthisis. It must still be held, therefore, that a *specific* curative or remedial agent for pulmonary phthisis — beyond simple nutritive and hygienic measures — is yet to be established.

URETHAN.

This is a generic name given to a class of ethers derived from carbonic acid, the name signifying the close chemical relation of this class of *ethers* to *urea*. "Urethan," however, has recently been employed to designate one of this class of ethers: carbonate of ethyl, or strictly speaking, "ethyl-urethan," having the formula C_2H7O_2.[27] The urethanes were known chemically as early as 1833, when Dumas and Cahours announced investigations concerning them be-

[25] Lyons Medical, December 5, 1886, and January 2, 1887.
[26] Lond. Med. Record, March 15, 1887.
[27] Eloy in L'Union Medicale, March 14, 1886.

fore the French Academy. Carbonic acid and urethanes were then successively studied by Liebig, Woehler, Gerhardt, Wurtz and others. In 1884 Schmiedebourg conceived the idea of therapeutic experiments upon animals with urethan, from theories of action founded on chemical constitution. Jolly and Von Jaksch, later Riegel and Stiker, employed it clinically. The researches of Huchard and Eloy and many clinical observers followed, and the drug became established as a hypnotic agent. Ethyl-urethan or urethan as it is ordinarily called, is a white crystalline substance very soluble in water, alcohol and ether, at all temperatures. It is prepared by the action of ammonia on chloro-carbonate or carbonate of ethyl, or by heating in a sealed tube a saturated alcoholic solution of cyanogen. Schmiedeberg's conclusions concerning its action were: That it depressed the cerebral functions, slightly stimulated the respiratory centre, was irritating subcutaneously. Von Jaksch's clinical observations were on twenty cases, in which he states it rarely failed to produce hypnotic action. Dr. Huchard [28] gives fourteen cases of which two only, from excessive coughing and dyspnœa in tuberculosis, failed to be benefited, in all the others quiet refreshing sleep was obtained from it, coming on in from ten minutes to an hour after the dose, and lasting four to ten hours, and neither attended nor followed by any digestive disturbance or headache.

Without going into detail concerning the very numerous reports of its action and clinical use, the following points may be considered as fairly well established. It is a hypnotic, acting chiefly by depression of cerebral centres, not sufficiently powerful to cause sleep if pain, persistent cough, great dyspnœa, or analogous conditions are present. It is of no value in delirium tremens. In simple insomnia, nervous sleeplessness from worry, over-excitement, etc., and in many forms of sleeplessness in insanity, it is very uniformly effective, producing restful, dreamless sleep, closely simulating physiological sleep. It is slightly stimulant to the respiration and does not depress the heart, even in toxic doses. This is a marked advantage in action over chloral. It has in ordinary doses no unpleasant after-effect, but very large doses produce gastric irritation with nausea and vomiting. Concerning the dose: twenty grains seems a medium dose. Huchard gave forty-five to sixty grains, and considered a single large dose better than several small doses. German observers recommend doses of fifteen to thirty grains (some seven and one-half to fifteen grains.) Ordinarily a single dose of fifteen to thirty grains at bedtime gives sleep without after-effects. The drug is not disagreeable in taste, and as noted, very soluble. Prof. Anress [29] has demonstrated the antagonistic action of urethan to convulsive agents like strychnine and picrotoxin. He considers it a safer and more effective antidote to strychnine than chloral. Its therapeutic action, if correctly observed, is certainly opposed to such a view, as it is said to act chiefly on the *brain*, while strychnine convulsions are from the *cord*.

HYOSCINE.

After the hyoscyanine was isolated from hyoscyamus, it was believed that another alkaloid or alkaloids were present, since hyoscyanine was, in *action*, essentially atropin, while hyoscyamus had a distinctly *hypnotic* action not possessed by atropin. This led to the discovery by Ludenbourg, in 1881, of hyoscine, another alkaloid, isomeric with both atropin and hyoscyanine, of the formula $C_{17}H_{23}NO_3$. Hölm and Reichardt had already employed the name "hyoscine" to designate a decomposition product of hyoscyanine, but Ludenbourg showed that product to be identical with atropin, and transferred the name "hyoscine" to the new alkaloid.

The pure alkaloid has not been obtained in crystalline form, but its salts, the hydriodate, hydrochlorate, and hydrobromate, have been so obtained, and are chiefly used, hyoscine itself being a syrupy body unsuitable for use. The hydriodate is moderately soluble in water, the hydrobromate and hydrochlorate readily soluble. Kobert's [30] experiments were with the hydrochlorate. His conclusions, in brief, from experiments on animals and clinical use are: That it acts on the vagus, peripheral bloodvessels, secretory system, and pupil, exactly as atropin, increasing pulse-rate by vagus paralysis, dilating capillaries, checking secretion of sweat and saliva, dilating the pupil. On respiration it seems to have little action in animals, in man it may produce dyspnœa on the spinal cord, no action on the brain; in animals little if any action; in man, hypnotic action, *weak* in conditions of *health*, but marked in conditions of disease of almost any form, most marked in disease with over-excitation of cerebral centres. Then clinical evidence for its use is abundant and very generally favorable. Dr. J. Mitchell [31] recommends it highly, from personal experience in its use, in cases of insomnia with restlessness, delirium, and other forms of cerebral excitation. He considers it a valuable addition to hypnotic agents, and says his experience is that "for the troublesome, noisy delirium which disturbs a ward for a whole night, there is no treatment at once so prompt, successful and safe, as a hypodermic injection of hyoscine. He further urges that too much must not be expected of it; it does not cure disease, but is simply hypnotic, temporarily removing delirium and securing quiet and sleep. Furthermore, that it should be used in cerebral cases only to combat urgent symptoms. It has some serious disadvantages in the way of occasional incidental effects. "Within a half-hour after the administration of a full dose, $\frac{1}{100}$ to $\frac{1}{75}$, it may cause failure of respiration in the form of rapid, shallow breathing, or even Cheyne-Stokes rhythm, at the same time the pulse may become weak and infrequent, the face livid, the pupils dilated." Cough is sometimes aggravated by it. On the other hand he gives cases in which he used hyoscine with perfect safety in double pneumonia, cardiac dilatation, and in chronic Bright's with delirium. Death has not, to his knowledge, in any recorded instance, been attributable to an overdose of this drug. He closes with the important statement, counterbalancing much that might seem adverse, that perfectly good results have been obtained from doses far short of those productive of the disagreeable incidental effects named, and that in his hospital wards he has found $\frac{1}{300}$ grain a useful working dose. He does not think it checks perspiration.

Drs. Francis L., and John R. Haynes [32] of Philadel-

[28] Bull. Gen. de Therap., Paris, 1886, cx, 103-110.
[29] Pharm. Post, October, 1886.
[30] Archiv. f. exper. Path. d. Pharm. xxii, 6, 396.
[31] Prac., Nov., 1886.
[32] Therap. Gaz., 1886, 304.

phia, report their results in fifty-seven cases treated with hyoscine, prefacing their report with the quotation "Facts, sir, Facts." Their facts are: That generally it produced one or more of the following symptoms: (1) Delirium, rambling or muttering, hallucinations of vision, etc. (2) Sleep, sometimes apparently natural, sometimes disturbed. (3) Intense reddening of the whole face, with sensations of heat. (4) Muscular weakness, sometimes extreme. (5) Headache. (6) Dryness of the throat. (7) Dilatation of the pupil.

Of these fifty-seven cases, hyoscine produced: (1) Sleep in fifteen. (2) Delirium in thirteen. (3) No marked effect or followed by various symptoms in twenty-nine. The article is headed "Hyoscine Hydrobromate," the drug always spoken of as "hyoscine" and stated to be of Marck's manufacture, also that "the alkaloid was dissolved in pure alcohol (grain $\frac{1}{100}$ to minims 20). The *dosage* is in many cases rather heroic, rarely less than $\frac{1}{100}$ grain, often $\frac{1}{75}$, sometimes $\frac{1}{50}$, once $\frac{1}{33}$, and of large totals in rapidly repeated doses; "$\frac{1}{17}$ grain in five doses in six hours" "$\frac{1}{16}$ grains in ten doses in twenty-four hours," "$\frac{1}{8}$ grains in four doses," "$\frac{1}{12}$ grain in divided doses," etc. The symptoms certainly indicate a close approach to "belladonna poisoning," but it is difficult to explain the failure to get any effect from some of the large doses given. Some other observers report cases showing unreliability of action, and suggesting lack of uniformity in the preparations of the drug. In the hands of many other reliable observers the salts of hyoscine have certainly given excellent results as hypnotic agents.

Concerning the *dose:* Bruce used the hydriodate, making a simple aqueous solution, one grain to two hundred minims. He says the dose of the hydriodate is $\frac{1}{100}$ to $\frac{2}{100}$, and that the average dose in America is $\frac{1}{100}$. His own experience is that the best results are to be obtained from doses of $\frac{2}{100}$ in all ordinary cases of restless insomnia and delirium, *without any risk of unpleasant effects.* If the symptoms are very urgent, $\frac{1}{100}$ or $\frac{1}{75}$ *with caution*, may be given. The hydrobromate is very much used, the ordinary dose being $\frac{1}{100}$ to $\frac{1}{50}$ grains. It is not irritating subcutaneously. When effective, its results are rapid, sleep in from ten to thirty minutes.

Dr. Tirard [33] regards it perfectly safe in renal disease, his inference, however, being from a single case in which its use over quite a long period, gave excellent results.

AMYLHYDRATE.

This is one of the most recent hypnotics, and has been introduced by Professor von Mering, of Strasburg.[34] This substance, which was first prepared by Wurtz, is a colorless fluid, which boils at 100 C, is dissolved by eight parts of water and is miscible with alcohol in all proportions. It has a peculiar ether-like taste suggesting camphor, and a cooling after-taste resembling that of peppermint. Besides the usual trials of this new drug on animals, Prof. von Mering has used it on sixty patients. The number of doses given was 350, a single dose varying between three and five grammes (45–75 grains.)

The majority of these patients were suffering from insomnia, among them two had cardiac disease, other cases included delirium tremens, phthisis, typhoid, rheumatism.

Doses of three to five grammes produced a quiet, refreshing sleep, which came on in half an hour and continued six to twelve hours. In only four cases was its action incomplete. Twice it proved serviceable in children suffering from whooping-cough; it was given in doses of 0.2 gramme in the evening.

In sleeplessness due to pain, its action like that of chloral is uncertain. Ill effects were not observed, nausea and vomiting did not occur, and digestion was not disturbed by its use. Headache was not a consequence of its use; in one case only the patient complained of a slight unpleasant feeling in the head.

So far as the taste goes, amylhydrate has the advantage of paraldehyde, and patients give the former the preference.

The exhalations do not have an unpleasant odor, as is the case with paraldehyde, and the dose is smaller.

The hypnotic action of amylhydrate is weaker than that of chloral, though stronger than that of paraldehyde. One gramme chloral affording the hypnotic action obtained from two of amylhydrate or three of paraldehyde.

Amylhydrate has this advantage over chloral: it has less action, even in larger doses, on the heart and respiration. It is, however, weaker than chloral, and cannot take its place where an energetic hypnotic is demanded.

CALOMEL AS A DIURETIC.

The use of calomel as a diuretic has been previously considered. Evidence accumulates to establish this action. Prof. Stiller,[35] of Buda-Pest, publishes eighteen cases of cardiac dropsy treated by calomel, confirming the essential views of Jendrassik, an enthusiastic advocate of this use of calomel. Cases with great œdema of the extremities, peritoneal and pleural effusions, enlarged and congested liver, with marked dyspnœa, were restored almost to health, certainly to comfort, by the administration of calomel, and this in several cases, where digitalis failed to relieve, or, from unfavorable action had been necessarily discontinued.

Prof. Stiller believes that in cardiac dropsy, not only for the removal of œdema, but also of effusions into the serous cavities, small doses of calomel constitute the most efficient and rapid means of relief. He found that generally diuresis occurred on the third or fourth day after the commencement of the administration, and occurred generally very suddenly and to a marked degree. He thinks it advisable then to discontinue the calomel until the diuretic action begins to pass off, when it should be renewed in smaller doses. He secured most marked diuretic effect without the least signs of mercurialization. In his first case, however, diarrhœa occasionally occurred, but this was remedied and prevented by the employment of opium with the calomel. In one case only did he get stomatitis. His doses were: 0.15–0.20 (2½–3 grains) three times a day, or 0.10 (1½ grains) five times a day. The urine generally jumped to a large amount on the third or fourth day (for example, 650 to 3200, 480 and 600, to 3600, etc.), and the calomel was stopped for two or three days, when the urine began to fall off in amount, and calomel was resumed. (He does not state in what doses.) With diarrhœa, or to prevent it, he gave 0.015 opium (¼ grains) with each dose of calomel. He adds that, combined with

[33] Prac., Feb., 1887.
[34] Therapeutische Monatshefte, July, 1887.
[35] Wiener Med. Wochster., July 10, 1886.

or alternating with digitalis, calomel is an especially powerful diuretic agent. While this evidence is unquestionably strong, it can hardly be expected to place the calomel treatment above or even equal to the treatment with digitalis and allied drugs. Prof. Stiller found that in *renal* cases the calomel treatment was ineffectual.

STROPHANTHUS.

This drug seems to be giving good results as a substitute for digitalis. Prof. Fraser, in a recent article,[26] says that the tincture should be made from the *seeds* only, and should be of a standard strength similar to that of tincture of digitalis. He recommends the use of such a tincture in doses of five to ten minims. Strophanthin, a white, crystalline substance, soluble in water, proves a very active toxic agent, fatal to dogs, in doses of 0.0002 per kilo., continued administration of much smaller doses proving fatal in four to seven days.

Clinical reports[27] indicate than strophanthus is not good in cardiac cases *with renal* complications, but in uncomplicated cardiac cases, is decidedly beneficial.

LANOLIN.

This substance is a cholesterin fat, differing from ordinary fat in containing cholesterin in place of glycerin. The peculiarity of cholesterin fats is that they do not decompose by boiling with alkaline solutions; that is, do not form soaps; they are, in other words, more stable chemical compounds than ordinary fats. Another peculiarity is their ready absorption of water, absorbing more than 100 per cent., by simply stirring with water. Ventral glycerine fats, vaseline and petroleum do not possess this property. "Lanolin" is made from the oil of sheep's wool, or "wool oil," which under the name of "œsypus" is of very ancient use by the Romans, and through the Middle Ages by the Continental races.

Its impurities, however, due chiefly to rancid, fatty acids, and giving it very repulsive characteristics, led to its abandonment. Liebreich has, however, succeeded in freeing this "wool oil" from its impurities, fatty acids, etc, and the resulting substance is that which he has designated "lanolin."[28] In his paper before the British Medical Association at Brighton, he calls attention to the fact that many so-called "lanolins" are on the market not at all answering to the tests of a pure neutral lanolin as obtained by his process. The advantages of lanolin are: That it is neutral, stable, readily miscible with water, highly absorbable by the skin. It is especially valuable as an ointment base for the treatment of skin diseases, and for medication through the skin.

Agnine, a still later product, is from the same source, with essentially the same properties, readily absorbing four times its weight of water.

Robinson — What was the amount of your doctor's bill, Dumley? *Dumley* — I paid him two hundred dollars. *Robinson* — Two hundred dollars! That's too much. *Dumley* — He saved my life, you know. *Robinson* — Yes, I know he saved your life. But two hundred dollars, Dumley! That's too much. — *New York Sun.*

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

G. H. MONKS, M.D., SECRETARY.

Meeting Tuesday, May 3d, 1887, Dr. J. C. Warren in the chair.

Dr. S. J. Mixter reported a

CASE OF MALIGNANT TUMOR OF THE BREAST,[1]

and showed the specimen removed.

He emphasized the importance of thoroughly cleaning out the axilla in all such cases, whether the glands were apparently free from disease or not. In order to avoid the tying down of the arm as a result of such a procedure, he employed a special kind of stitch by which the skin was drawn up into the apex of the axilla, thus obliterating the dead space there, which would otherwise exist. He stated that he claimed nothing especially original for this method, but that he had been prompted to employ it because surgeons had considered the obliteration of the "dead space" in the axilla of so much importance that it had been proposed to fill it in with a special flap cut for the purpose. He thought the axilla should be opened up by an incision made close to the border of the pectoralis major.

Dr. W. F. Whitney said that the histological investigation in this case fully corroborated the statement of Dr. Mixter, as to the necessity of a complete removal of the tissue from the axilla, in case of cancer of the breast. For in the apparently normal fat tissue he had often found minute glands, which would escape anything but a microscopic examination, presenting evidences of implication.

In the tissue hardened and stained in the ordinary way the presence of the epithelial cells could only be made out with difficulty, from the much greater abundance of the ordinary lymphoid cells. If, however, a scraping was made from the fresh specimen and examined in a three-quarters per cent. salt solution, they could be readily seen and differentiated. In this earliest stage they apparently lie in twos or threes in the lymph channels, and have not as yet formed the typical alveolated structure.

Dr. Ingalls thought that every conscientious surgeon at the present time must believe that in all cases the axilla should be cleaned out, so as to anticipate, if possible, any recurrence of the disease.

He considered the suture, which was apparently a carefully considered modification of the old "button-suture" well calculated to pull up the skin into the axilla after operation.

Dr. O. K. Newell said that he had seen the suture as applied by Dr. Mixter, and was convinced of its efficacy.

The Chairman said that as a means of getting as little axillary web as possible and thus securing a good range of movement for the arm, he thought the plan of pulling up the axillary skin an excellent one. He had known patients to complain of limitation of movement in cases where no attempt had been made to prevent the formation of an axillary web.

The practice of removing the axillary glands in cases of cancer of the breast is now generally adopted. Though it complicates the operation, it has the advan-

[1] See page 328 of the Journal.

tage of more radically removing the disease. It also prevents incompetent practitioners from attempting the operation.

DR. H. P. BOWDITCH was much interested in the statement of the reader that the tumor had grown rapidly under massage. He said that he could imagine that massage might assist the dissemination of cancer, since passive movements are well known to help the circulation of the lymph.

DR. E. G. BRACKETT then read a paper on the

EXPERIMENTAL VALUE OF THE DOWSE SPLINT.[2]

The splint itself was shown, and its construction and working thoroughly explained. By means of numerous diagrams taken from instantaneous photographs of the positions of the body in the various stages of walking, Dr. Brackett showed how well the splint was calculated to allow the leg the motions of walking and at the same time to remove pressure from the hip-joint.

DR. E. H. BRADFORD stated that the appliance was not so widely known as it should be. It was as original, as complete an adaptation of mechanical ingenuity to meet surgical indications as Buck's extension or Bigelow's litholapaxy, and as efficient. It was entirely an American invention.

In every case of hip-disease successfully treated, there comes a stage, during which fixation is no longer needed, and extension becomes unnecessary. The joint is practically well, but protection is needed against jar, to prevent relapse. This can be done by means of crutches, but children leave crutches aside if walking causes no pain, and adults need their arms. The appliance shown protects the joint and enables the patient to walk about freely. Theoretically, criticisms have been urged against the appliance that it does not protect the joint. How it actually does, Dr. Brackett has shown, thus demonstrating experimentally the uses of an appliance which clinically has been found of service.

Dr. Brackett's perineal strap is of great assistance, particularly in adults, relieving the discomfort of a narrower pad. The weight of the splint is its only drawback.

DR. E. O. OTIS read a paper on

INJURIES TO, AND OPERATIONS UPON THE KIDNEY,[3]

and showed by diagrams the various incisions which had been recommended for operations upon that organ.

DR. JOHN HOMANS referred to two cases of abscess of the kidney in which he had operated, the one by the abdominal and the other by the lumbar incision. In one of the cases several small calculi were removed. Unfortunately, however, the result in both cases was a fatal one.

He thought that an operator contemplating the extirpation of a suppurating kidney, should first thoroughly drain it through an incision in the loin.

DR. H. L. BURRELL said that he recalled two cases that might be of interest in connection with Dr. Otis's paper. The first was that of a woman who had been sent to him to be operated upon for an ovarian tumor; on examining her he found a suppurating movable kidney of the left side. He exposed the tumor through the flank with the intention of removing the whole kidney, but found, owing to the lack of space between the floating ribs and the crest of the ilium, that this would be impracticable, and consequently he simply drained the pelvis of the kidney. The patient died in twenty-six hours with suppression of urine. The autopsy showed extensive disease in the other kidney. The case illustrated to his mind that in certain cases where nephrectomy was planned, the operative procedure could not be carried out through a lumbar incision. The second case was that of a man who had had symptoms of stone in the kidney for several years, who had been the rounds of the different hospitals, and finally consented to be examined under ether and have the renal area aspirated. As fortune would have it, the first plunge of the needle came down on the stone (this was verified by several gentlemen present in the amphitheatre of the hospital); unfortunately Dr. Burrell had not obtained the patient's consent to remove the stone. Within a few days, after obtaining the patient's consent to the operation, the patient was again etherized and the kidney freely exposed through the usual lumbar incision.

The stone was searched for most diligently, the kidney was explored in all directions by means of a grooved needle, but no stone could be found. Nephrotomy and nephrectomy were considered unadvisable, as the kidney was apparently a healthy one. The patient made a recovery; on the twelfth day he had a sharp secondary hæmorrhage from the sides of the lumbar incision, which was easily controlled by pressure forceps.

Strange to relate, the patient has been greatly benefited by the operation, and the symptoms of stone have entirely disappeared, he having been restored to apparent perfect health.

Dr. Burrell thought that this case illustrated the occasional benefits derived from an unfinished operation. Regarding the expediency of nephrectomy in such cases, he cited a case where Mr. Henry Morris[4] removed a healthy kidney by lumbar nephrectomy which had imbedded in it a calculus, the size of a marble; even after the removal of the kidney, the locality of the stone could not be made out by pressing the organ between the finger and thumb; nor by pressing the kidney as it lay upon a table. Only after section of the organ was the calculus demonstrated.

DR. F. S. WATSON said that his own experience in operations upon the kidney had been small, being limited to three cases of lumbar incision, twice for perinephritic suppuration, and once for an acute hydronephrosis, due to obstruction from stricture of the ureter. He thought that the incision in cases of calculous nephritis, where the endeavor was being made to extract the stone, should if possible be made through the substance of the organ rather than through the pelvis of the kidney, because thus a better chance of the wound's healing without leaving a urinary fistula, was afforded. Hæmorrhage had been a prominent feature in the cases that he had seen, however, where the tissue of the gland was divided, but of such a character, that it could generally be controlled by pressure from packing the wound.

The choice of the abdominal or lumbar incision depended upon the nature of the case. Where draining a suppurating cavity, or the removal of stone, or the fixing of a movable kidney was contemplated, lumbar nephrotomy seemed to be the best operation. If nephrectomy were intended, the question was more

[2] See page 321 of the Journal.
[3] See page 349 of this number of the Journal.
[4] Dis. of Kidney, Henry Morris, Pl. iv, p. 827.

doubtful, and in spite of the greater mortality of the abdominal operation, it would often be the better one, on account of the greater extent of the field of operation.

It should be remembered that anomalies occasionally occurred in the renal artery, which instead of being always given off as one branch, sometimes came off the main vessel in two or three branches, so that they might not all be secured in the pedicle in a nephrectomy, and give rise to dangerous hæmorrhage before they had been secured.

The operation of nephrectomy seemed of doubtful advantage in cases of malignant growth.

Dr. Mixter believed that in primary operations for suppurating kidney, the question as to whether the kidney should be removed or not, generally settles itself as soon as the kidney is reached. In some cases the interior of the kidney is converted into one large abscess cavity, of which the thinned and atrophied kidney substance forms the wall. Excision in such a case is, of course, impossible.

Dr. H. W. Cushing said that the allusions to the want of sufficient room for operation, recalled the incision first suggested by König, known as the "retroperitoneal lumbo-abdominal" (Lendenbauchschnitt) incision.

The advantages claimed are that it makes the kidney surprisingly accessible, that it can be lengthened if the operation requires, and finally, that the surgeon can perform a postperitoneal or an intraperitoneal operation as the conditions presented indicate through the same incision. It has been claimed that this operation, on account of the extensive division of broad muscular layers was especially subject to subsequent ventral hernia. Dr. Cushing inquired if the reader had seen any reports of this accident having occurred? Dr. Otis replied that he had not.

The Chairman stated that nephrotomy for stone was becoming a more frequent operation. By this is meant the operation upon the otherwise healthy kidney, and not merely the removal of a calculus from a suppurating kidney. One or two such operations had recently been performed in this country with satisfactory results. As to the best place to make the incision for removal of the kidney, that depended upon the size of the organ. In large tumors the linea semilunaris offered the best opportunity to explore through.

He thought it required considerable experience to decide upon the question of operative interference in tumors of the kidney, and that the majority of cases of malignant disease of the kidney had better not be meddled with.

Dr. Homans showed several

ABDOMINAL TUMORS,

recently removed.

The first was a large dermoid cyst of the ovary, containing teeth and hair. The latter was matted into a bunch nine-and-a-quarter inches long.

The second was a fibroid of the uterus, weighing seventeen pounds, from a woman forty-five years old.

The third was an ovarian cyst from a woman who weighed over two hundred pounds. The operation was complicated by the unusual depth of incision necessary to reach the tumor, the fat upon the abdominal walls being about six inches thick. The tumor was also extremely adherent. The fluid from the tumor weighed sixty-six pounds.

AMERICAN GYNÆCOLOGICAL SOCIETY.[1]

Twelfth Annual Meeting.

WEDNESDAY, SEPTEMBER 14TH. — SECOND DAY.

AFTERNOON SESSION.

A CASE OF ACUTE DILATATION OF THE STOMACH FOLLOWING LAPAROTOMY,

by Dr. James B. Hunter, of New York.

The patient was a married woman, aged twenty-five years. Had been married four years, but never pregnant. Menstruation was painful, and quite profuse. There was severe pain in the lower part of the abdomen, aggravated by walking. For four years, she had been the subject of right inguinal hernia. There was no emaciation. She had been subjected to long-continued treatment without benefit. Examination showed marked endometritis, with prolapsed and painful ovaries. Tait's operation was decided upon. Previous to operation, the patient was subjected to a careful physical examination, and no organic disease found. There was nothing unusual to direct attention to the stomach. The operation was performed in the usual manner, the pedicles being secured with catgut, and returned to the abdominal cavity. Following the operation, there was continued nausea and vomiting, and the patient died on the ninth day from exhaustion. At the autopsy, the abdominal cavity was filled by the dilated stomach, which extended to within three inches of the symphysis. The stomach contained a gallon of dark, sour fluid. There was no obstruction of the pylorus. The mucous membrane showed evidences of chronic inflammation, and there was marked atrophy of all the coats.

There are cases on record in which acute dilatation of the stomach occurred under almost similar circumstances, but the cause of this condition is very obscure. This patient had an inguinal hernia — which, it has been claimed, may cause dilatation of the stomach by traction on the fundus. This case points to the fact that there should be greater vigilance in searching for other conditions than those in the pelvis. We should carefully exclude diseases of all other organs, diseases which may determine the result in laparotomy.

THE INTRA-UTERINE STEM IN THE TREATMENT OF FLEXURES,

by Dr. A. Reeves Jackson, of Chicago.

The object of the paper was to present the results which he had observed in a selected class of cases, and to explain the details of the method used. A large proportion of flexions of the womb do not need any treatment, others are wholly unamenable to treatment, while others are made worse by attempts at treatment. The author began the use of the stem-pessary in 1870. Previous to that time, he had used dilatation of the cervical canal, and incision of the cervical wall, separately or combined. The results were unsatisfactory. All the cases thus treated relapsed. The single symptom which was regarded as an indication for the treatment of a flexion was dysmenorrhœa.

Details of the method. Having determined the presence of a flexion, a flexible, olive-tipped bougie is introduced, and allowed to remain from two to ten minutes, according to the amount of irritation produced. This is repeated at intervals of from one to three days. The size of the bougie is gradually in-

[1] Continued from page 336.

creased. This treatment is continued until tolerance is induced. Then, at the close of a menstrual period, a soft rubber stem, one-third of an inch shorter than the uterine canal, and of a size that can be readily introduced, is passed into the uterus, and maintained in position by a tampon soaked with glycerine. The tampon is removed after two or three days, and is repeated as long as there is any tendency for the stem to slip out. This soft stem should be worn six or eight weeks, when it should be replaced by a larger stem, and in six or eight weeks, a still larger one. As soon as the womb can be readily straightened, a more rigid stem should be employed. This should be of vulcanite. The pessary should not be such as will stretch the internal os, but above this point, it may, with advantage, have a bulge. In a few cases, it was not found necessary to resort to the stiff instrument.

The hard stem is worn continuously for three months. It is then removed for a week or ten days. If there is then found a tendency to return to the former condition, the stem is again introduced, and worn for another period of three months. The essential principle in this plan of treatment consists in its gradual conduct. The uterus must be coaxed, not forced, into proper shape. Any method of treatment which involves the rapid removal of the flexion is dangerous, and not liable to be of permanent benefit. In no instance has inflammation followed the use of the stem. Where the flexion is maintained by adhesions, or where there is evident inflammation, the stem is not to be employed.

The stem has been used by the author in sixty-seven cases, forty-three married, and twenty-four unmarried. Nine of the former had borne children, and eight of the latter subsequently became pregnant. Forty-one of the cases were cured, five improved and relieved of dysmenorrhœa, and in twenty the result was not known.

DISCUSSION.

Dr. Ogden, of Toronto. I am perfectly in accord with Dr. Jackson's paper. There is no use in trying to straighten the uterus suddenly. When the uterus is accustomed to the presence of a foreign body, the stem-pessary is calculated to do a great deal of good. To retain the stem in position, I use dry, non-absorbent cotton, dusted with boric acid, in preference to the moist cotton. This can be left in three or four days.

Professor Laurence, of Bristol, Eng. In England, intra-uterine stems are in great disfavor. My own plan has been similar to that of Dr. Jackson. I use the stem in selected cases, where the only cause of the dysmenorrhœa is the bent condition of the uterus. I gradually prepare the uterus for the use of a stiff instrument. I would relate the following case: A married woman, aged thirty-five years, was sterile, and suffered with dysmenorrhœa and inter-menstrual hæmorrhage. After wearing the stem for two months, the bleeding ceased, and the dysmenorrhœa disappeared. In six months I removed the pessary, and the woman became pregnant. I have had many such cases. The first thing is to be sure that the trouble is due entirely to the bent condition of the canal. I have dilated canals, and incised them, but never with the results that I have obtained from the intra-uterine stem.

THE TECHNIQUE AND TREATMENT OF UTERINE FIBROMATA BY ELECTROLYSIS,

by Dr. G. Apostoli, of Paris, France.

The paper was read in French. The author described in detail the method of treating uterine fibroids, which he had recommended. He has found electrolysis successful in checking the growth of the tumor, and in decreasing its size. He does not regard the plan of treatment as dangerous, having lost but two patients out of two hundred cases, and in these instances death was not directly attributable to the operation. He has also used this method for the relief of nervous pain in hysteria, employing the constant current, long continued. This also relieves pain associated with effusion. In four cases, galvano-puncture per vaginam has cured ovarian cysts after the treatment has been continued two years.

DISCUSSION.

Dr. James R. Chadwick, of Boston. I am sorry to say that my results have not been so satisfactory as those of Dr. Apostoli. For the past six months I have employed this method. I must, however, say that the current has not been applied as frequently as has been recommended by the author. I have used this method in from twelve to fifteen cases. The greatest number of applications was seventeen or eighteen. Several cases received seven or eight applications. Others received a less number. In one case of small fibroid, after five or six applications, the length of the uterine canal was diminished from 3.75 inches to 3.25 inches. In a case which received seventeen applications, I could detect no change. In two cases of multiple fibroids, one or two applications were followed by fever and pain, and what might be called metro-peritonitis. Both recovered. In two cases death has followed the treatment. In one case the tumor was smaller than the fist. The patient went home after the application and the next day began to have pain in the pelvis. I saw her on the fifth day. She then had acute metro-peritonitis and died on the eighth day. No autopsy was made. The second case was one of enormous fibroid springing from the posterior lip and filling the vagina. The treatment had been carried on for some time by another gentleman, with good results. The case was then referred to me. I made five applications, in every instance following the aseptic method closely. The fifth application was followed by septic infection. This was followed by profuse suppuration, and at the end of four weeks the patient suddenly died of what I suppose to have been pulmonary embolism.

VENTRAL HERNIA AFTER LAPAROTOMY AND ITS SURGICAL TREATMENT,

by Dr. James R. Chadwick, of Boston.

The history of cases of ventral hernia following laparotomy, shows that the affection does not appear immediately, but usually a year or more, later: The protrusion tends to increase steadily until it may assume enormous proportions. The use of pads and trusses to arrest the progress of the lesion has, as a rule, been of little value. The hernia causes a dragging sensation, colicky pain, meteorism and indigestion. There is liability to inflammation of the sac or to its rupture. Strangulation has not supervened in any case of hernia after laparotomy. The frequency of this lesion is probably greater than is appreciated.

Early operations probably tend to increase the liability to hernia, for the abdominal walls are then more tense than after the removal of a large tumor. The use of the drainage tube may favor its development, and in these cases it was suggested that a suture be placed on each side of the tube and when the tube is removed they can be tightened, thus closing the opening. In regard to the cause of the hernia much stress was laid upon the fact that in the operation, the fascia covering the rectus muscle was cut. The two portions of this fascia at once retract, and if not brought together when the wound is closed, will leave a weak spot. The hernia results from the failure to unite the musculo-aponeurotic layers.

The following case operated on by the author in April, 1887, was described: The patient was a woman, forty-four years of age, of strong, muscular development. In 1872, she had an ovarian tumor, weighing sixty pounds, removed. The abdominal incision was closed with unusual haste on account of the collapsed condition of the patient. The pedicle was secured with the clamp in the lower angle of the wound. Three years later the wound began to bulge. Every form of truss was applied, but the hernia gradually increased. The menstrual periods lasted ten days, one-third of the quantity of blood escaping from the stump. There was severe lancinating pain in the hernia. The skin over the lower portion of the hernia was extremely thin and the patient was in constant fear of rupture. The abdominal walls were loaded with three or four inches of fat. The operation was performed under strict aseptic precautions. The whole sac was laid open. Ten silk sutures were passed through the integument, three inches of fat through the rectus muscle and peritoneum one inch from the edge of the opening, and then through the opposite side. The abdominal tension was very great.

The convalescence was uneventful although there was considerable suppuration in the cellular tissue. The union was ultimately complete and firm. Five months have elapsed since the time of operation.

THURSDAY, SEPTEMBER 15TH.— THIRD DAY.

Discussion of DR. BANTOCK'S paper on

THE TREATMENT OF THE PEDICLE IN SUPRO-VAGINAL HYSTERECTOMY.

DR. A. MARTIN, of Berlin. The principal objection to the dropping of the pedicle is the danger of hæmorrhage. This danger, I think, does not exist. In Berlin, it is the practice to treat the pedicle by the intra-peritoneal method. In performing this operation, I surround the pedicle with Esmarch's constricting apparatus. In removing the body of the uterus, a V-shaped excavation is made in the cervix. The upper portion of the cervical canal is then dissected out, and the lower portion carefully disinfected. The cavity thus formed is brought together with sutures. Next, the two flaps of the cervix are united, and then the edges of the peritoneum are brought together. In this way, danger of hæmorrhage is avoided. I think that the method of fixing the pedicle will have little influence on the development of sepsis. Many of these patients die from the effects of their disease. The intra-peritoneal method of treating the pedicle is certainly the ideal method. In the treatment of ovarian tumors, the intra-peritoneal method was first employed, and then a great advance was made when it was treated outside, but now the general rule is to drop the pedicle in these cases.

Up to the end of 1886, I had had eighty-four supra-vaginal amputations of the uterus. Of this number, ten died of sepsis, and seventeen died of collapse following embolism. This series includes a number of very unfavorable cases. Of my last thirty supra-vaginal hysterectomies, I have lost three.

DR. A. R. SIMPSON, of Edinburgh. I do not think that we can say that either method of treating the pedicle is the best in all cases. Each case must be decided by the conditions met with in that particular case. I think that, in the treatment of fibroid tumors, the clamp will hold its ground, for the reason that, in this way, the pedicle can be secured in a much shorter time, and this is an important point.

Dr. Bantock has objected to the use of iron. I agree with him that the solution of the perchloride should not be used, for it is difficult to confine a liquid to the desired point, but the persulphate, in the form of a powder, does not offer this objection. I have used this in combination with iodoform and bismuth powder over the stump, with entire satisfaction.

DR. WILLIAM GARDINER, of Montreal. My experience amounts to only five or six cases, but, in these, I have used the clamp, and, so far, I have seen no reason to change my mode of procedure. The best results, so far, have been obtained from the extra-peritoneal method.

DR. H. MARION SIMS, of New York. I have employed the extra-peritoneal method in the hysterectomies which I have performed. I have seen my father employ the intra-peritoneal method with such unfavorable results, that I have feared to try it. I have had eight cases, of which two died of sepsis, the result of sloughing of the stump.

DR. MATHEW D. MANN, of Buffalo. I have had six cases in which I have removed the uterus or fibroid tumors from the uterus. In the first case, where I removed a fibroid tumor weighing fifteen pounds, I encircled the pedicle with a ligature, and dropped it. Six hours later, the woman was in a state of collapse from hæmorrhage. I opened the abdomen, and secured the pedicle with a wire clamp, and the woman recovered. Since then, I have always used the clamp. All my cases have recovered. In the after-treatment of the stump, I have rubbed it with iodoform, packed cotton around it, and left it exposed to the air. In this way, it dries quickly and becomes perfectly hard.

DR. G. G. BANTOCK, of London. I would call attention to the fact that, while my mortality from the extra-peritoneal method of treating the stump has been twelve in seventy-two cases, that of Dr. Martin in the intra-peritoneal method has been twenty-seven in eighty-four cases. The number of cases, however, is not large enough to be of much value. The proportion of septic cases with the intra-peritoneal method was greater than with the extra-peritoneal method. In regard to the use of iron, I believe that it is a mistake to apply anything to the stump. If the pedicle is properly trimmed, it becomes as hard as horn in two or three days. The greatest care should be taken in bringing the edges of the peritoneum accurately together, so that nothing may pass down from the stump.

(To be continued.)

NEW YORK STATE MEDICAL ASSOCIATION.[1]

SECOND DAY.— MORNING SESSION.

RECENT AND NEGLECTED CASES OF DISLOCATION OF THE RADIUS AND ULNA, UPWARD AND BACKWARD UPON THE HUMERUS.

Dr. Uri C. Lynde read a paper with this title. Only neglected cases of dislocation of this kind had come under his observation. When allowed to remain unreduced the deformity was considerable, and the function impaired if not entirely lost. This dislocation became the soonest irreducible. He first considered reduction when recent. The surgeon had to deal with three factors; muscles, ligaments and bones. In all cases in which the brachialis anticus remained intact, it was the chief factor on which the surgeon relied to accomplish reduction. Dr. Lynde thought the mechanism of reduction in these cases depended upon the flexion of the forearm upon the arm, and not upon pressure upon the radius and ulna. There were but two indications to accomplish reduction, the first being to remove the coronoid process from the olecranon fossa, the second, to aid the brachialis anticus to draw the humerus into position. There were two methods, the one by over-extension and traction, the other by flexion and traction. By the first method the coronoid is lifted from the olecranon fossa; by the second it is rolled from it. In both methods, traction from the wrist is practised to aid the brachialis anticus in drawing the humerus into normal position. Should this muscle be torn, traction will be aided by the biceps. Soon after the dislocation the patient is himself able to reduce it, but after some weeks or months reduction is very difficult. Dr. Lynde here gave reasons for this increased difficulty in reduction with the lapse of time. He objected to the practice of over-extension in old cases as it endangered the vessels. Flexion was safe; that is, it did not involve danger to vital parts. If necessary, the triceps might be cut, and some surgeons drilled the coronoid process subcutaneously to weaken and break it. If necessary to retain the parts in place, a splint might afterwards be worn.

Dr. E. M. Moore favored over-extension in the reduction of old cases. He doubted whether there was much danger to the bloodvessels and nerves.

Dr. Carman, of New Haven, thought it unnecessary to put the knee in the bend of the elbow while practising reduction, as it was equally unnecessary to insert it in the axilla in reducing a dislocation of the shoulder; the thumb answered the purpose as well as the knee.

Dr. J. W. S. Gouley, of New York, then read

AN ADDRESS ON NOSOGRAPHY.

The object of the essay was to urge official adoption of a human nosography founded on a stable basis; to place before the medical profession a criticism upon the nosography of diseases in general, and of affections of the male urinary genital apparatus in particular; to awaken the attention of teachers to the necessity for improving the nomenclature of medicine, pointing out some misused words and proposing others for their consideration; to summarize modern views on the pathoanatomy of urinary genital affections, and indicate methods of diagnosis and treatment considered to be safest and most efficient. Dr. Gouley criticised the use of the word "system" in the phrase genito-urinary system. It should be discarded for the word apparatus. The same in speaking of the genital and other apparatus, the word system should not be employed. The work of nosographers of the past was reviewed.

The paper was referred to a committee composed of Drs. Carroll, Moore and Cronyn, who were afterwards given power to add to their number.

SECOND DAY. — AFTERNOON SESSION.

DISCUSSION ON TYPHOID FEVER.

Dr. Alfred L. Carroll opened the discussion with a paper in which he raised the following seven questions, namely:

(1) Does the term typhoid fever properly include all the varieties described by observers; or are there other, still undifferentiated, continued fevers commonly grouped under this head?

(2) Is typhoid fever always the product of a specific contagium from a pre-existing case; or may it arise, *de novo*, from filth-fermentation.

(3) What part is played by micro-organic ferments in the causation of enteric fever?

(4) Is there a disease of the lower animals transmissible to man as typhoid fever?

(5) What media of causation or transmission of typhoid fever are to be guarded against in public or private sanitation?

(6) What are the complications and sequelæ properly associated with typhoid fever?

(7) What are the indications for treatment, and are relapses or untoward complications favored by some antipyretic measures?

Speaking to the first question, the author thought that some of the described varieties of typhoid fever differed the one from the other as widely as the general group differed from typhus fever. The general experience of the profession had taught us not to place implicit reliance upon the temperature, or other one clinical phenomenon, in diagnosticating the disease. Nor was the diagnosis always cleared up by the necropsy. He thought we were justified in speaking of a specific exanthematous fever with local lesions in the intestinal glandular apparatus, apparently developed only from changes which took place in the excreta of a previous existing case, and which might, until a clearer idea of the pathology was obtained, be entitled enteric fever. One attack, as a rule, afforded immunity for the future. There were many well-authenticated cases of adynamic fever occurring in isolated rural districts where no connection with a previous case could be discovered, but it had not been proven that such cases were undoubtedly those of what might be classed as enteric fever. Adynamic fevers, resembling typhoid or enteric fever in the clinical history could be traced to filth-fermentation.

Speaking of the fifth question, he said the most common source of danger was the water. The filtering power of the soil might be over-taxed; nor could implicit reliance be placed in artificial methods of purification. The simplest method was to boil the water half an hour. In public practice, the only wise rule was to see that the water-supply was absolutely uncontaminable by drainage.

As to the seventh question — what are the indications for treatment? — he said purity of air, water, and soil was as essential to recovery as to the preserva-

[1] Continued from page 340.

tion of health. We should try to maintain nutrition. Cold baths might be useful in certain cases, but their routine adoption was to be deprecated. It was a question whether more relapses did not take place when antipyrine was employed.

Dr. E. G. Janeway, of New York City, discussed the first two questions, but the first he changed as follows: Do we encounter, in this state, a form of continued fever not due to typhoid poison, and liable to be mistaken for typhoid fever?

Every physician having had any experience must admit to having had doubts regarding the nature of the poison which had excited the fever in certain cases. Typhoid fever was no more bound in its course to rigid rules than was pneumonia. The writer had seen, in the course of a single year, as many as twenty cases of typhoid fever, which had been called remittent, typho-malarial, and simple continued fever. He did not think types had changed so much as had the diet and treatment, which latter would account largely for the diminished frequency of diarrhœa.

Those engaged in private practice, and those in the country, where it was difficult to get an autopsy, were the strongest upholders of the view of the divisibility of the cases of typhoid fever. Many cases of true typhoid fever in isolated places were regarded as malarial, typho-malarial, etc. Regarding typho-malarial fever, he was of the opinion that a large proportion of the cases in this latitude were cases of pure typhoid fever. He had seen no reason to credit a cause to be known as a typho-malarial cause of an acute or separate disease process, but certain cases with previous malaria, in which typhoid fever developed, modifying the course of the disease, had given rise to the supposition. It would be wiser to stick to the nomenclature of typhoid fever, and look upon the malarial element as a complication.

As to the second question, he admitted a germ as the original cause of typhoid fever; but when the question was asked — did it always arise from a pre-existing case? — we encountered trouble. That it had often arisen from previous cases could readily be proven, but it was difficult to prove that it was *always* due to a previous case. Dr. Janeway had found but very few recorded cases in which it appeared that the disease had developed in entirely isolated surroundings, such as seemingly to preclude the possibility of contagion derived from another case, and in none, he thought, had the proof been altogether beyond question. He was willing to entertain the possibility of a spontaneous origin, but he could not admit that it had been proven beyond doubt.

Dr. Hermann M. Biggs discussed the third question. He summed up as follows: There are invariably found in the spleen, mesenteric glands, Peyer's patches, sometimes in the liver and kidneys, in cases of typhoid fever, peculiar, short, thick bacilli. This bacillus is the only organism found in uncomplicated cases of this disease in the internal organs, and is never found in any other condition of health or disease. All experiments thus far to produce typhoid fever in lower animals have been unsuccessful. The bacillus, as present in the stools of typhoid fever patients, has been found, in a few instances, in the water which has been the source of the disease.

D. E. Salmon, D.V.S., of Washington, discussed the fourth question without notes. The facts which came under his observation were necessarily of a one-sided character. Typhoid and other infectious diseases, in man, he saw only in exceptional cases. He had no reason to suppose that there is a specific disease in animals which produces a specific disease in man attributed to the bacillus just described. The bacillus in the cholera of hogs seemed to be identical, in microscopical appearances, with the bacillus described in typhoid fever of man, and it was similar in its ability to live and multiply in reasonably pure drinking-water. But, in spite of the fact that hog-cholera is so common in this country, no facts had come to his knowledge to show that it had produced a specific disease in man. He hoped that, in the future, we should be able to separate the specific ptomaines produced by the growth of the specific virus of the different contagious diseases, and, by using these, be able to produce a degree of immunity equal to that produced by one attack of the disease. The only way in which we have been able to produce immunity by the use of ptomaines, thus far, has been by hypodermic injection.

He thought that, for the advancement of science, there should be more sympathy of work between those who made a study of the diseases of man and those who studied the diseases of animals.

Dr. Charles A. Leale and Dr. Everard D. Ferguson discussed the fifth question. The former dwelt considerably upon the disposal of sewage by vegetation on garden-farms, and to the labors in this direction of Dr. Carpenter. He expressed sympathy for the over-worked hospital interne, who was peculiarly disposed to contract typhoid fever when exposed to the poison.

Dr. Ferguson gave the history of two epidemics of the disease in a portion of Troy, in the first of which it was traced to the water-supply from wells which tapped a superficial underground basin; in the second, to the water and air at the time of an overflow.

Dr. Charles G. Stockton discussed the seventh question, and said that the greatest attention should be given to the diet. Only a limited amount could be assimilated, and should be given in the form most easily digested. It should be peptonized. To reduce the temperature, he would try sponging first. The injurious effects of antipyrine, etc., doubtless was often due to their abuse, rather than to the fact that they were contraindicated. It was most important to provide an airy, sunny, quiet room, a large, single bed, and a good nurse, first and last.

(To be continued.)

Recent Literature.

Cyclopædia of Obstetrics and Gynæcology. Vol. 6: Gynæcological Examinations, Minor Therapeutic Manipulations and Elementary Operations, Operations on the Ovaries. By Dr. A. Hagar and Dr. R. Kaltenbach. Vol. 10: Diseases of the Female Urethra and Bladder. By F. Winckel, M.D., and Diseases of the Vagina, by A. Breisky, M.D. New York: Wm. Wood & Co. 1887.

The publishers of these volumes are well known for their enterprise in bringing before the medical profession, each year, a series of works at a moderate price, embracing original monographs and translations, the volumes being issued monthly, and sold only by sub-

scription as a set. This year, instead of a variety of subjects, as has usually been the case, they have confined themselves to obstetrics and gynæcology; and, in the twelve volumes, some of which have already appeared, propose to so well cover the subjects comprised under these two heads, as to warrant the name of Cyclopædia for the completed work.

The two under consideration are the first which have appeared treating of gynæcological subjects. Volume 6 is a translation of the first part of Hegar and Kaltenbach's well-known work on "Operative Gynæcology," which has been a standard book in Germany for many years, and Volume 10 needs nothing more than the well-known names of its authors, Winckel and Breisky, to recommend it. We are heartily glad to see both of these brought within the reach of the large numbers of our profession who cannot read them in the original, and feel sure that who ever subscribes for the complete set will not regret the outlay. It is an opportunity to obtain, at a moderate cost, books which rank among the best that have appeared in Germany. The translation is, in general, very carefully done, and the volumes are issued in a very neat and attractive form.

Anatomical Research in the Human Rectum, and a new Method of Rectal Inspection. By WALTER J. OTIS, M.D. Part First. Leipzig: Veit & Comp. 1887.

This is a very handsome monograph printed in German and English in parallel columns, and illustrated by eight fine plates and one wood-cut. This first part of Dr. Otis's work treats only of the rectum of the male cadaver, the new method of examination in the living being reserved for a future one. Dr. Otis's investigations, begun at the Harvard Medical School, where he was one of the assistants in anatomy, have been continued in Professor Braune's department at Leipzig.

The mucous membrane and the muscular layers of the rectum have been thoroughly studied, and the results clearly expressed. The essential point of the paper is that the rectum is sacculated, like the colon. Many readers will, we imagine, be disposed to think the figures of the folds of the plates exaggerated, but we are convinced from the study of preparations at the Harvard Medical School, made by Dr. Otis, that such is not the case. He does not believe in the existence of the third sphincter. He believes that the gathering together of the circular fibres in the folds of the rectum is for the purpose of expelling the contents, as Dr. Chadwick has already maintained, but he does not explain, as he should, how a system of folds is a help, rather than a hindrance. Dr. Otis states that the lowest fold on the right is the largest, and marks, in a general way, the lowest point of the recto-vesical fold of the peritoneum. He suggests that this be known as the *plica transversalis* of Kohlrausch. In conclusion, we have to thank Dr. Otis for two things: first, that he has omitted an historical chapter; and secondly, that he has given a full bibliography of the subject. T. D.

— The New York Academy of Medicine recommenced its meetings after the long vacation, on October 6th, with a discussion on "The Modern Method of Treating Syphilis," which was opened by Dr. P. A. Morrow, and participated in by Drs. E. B. Bronson, E. L. Keyes, R. W. Taylor, F. R. Sturgis, and others.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 13, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

TYPHOID FEVER.

As we are now passing through the season of the year when — whatever the cause or causes may be — typhoid fever ordinarily reaches its maximum prevalence, especially in large cities, the old subject offers its renewed periodical interest, and the latest expression of opinion of those who have given it their study attracts attention.

At the recent meeting of the New York State Medical Association, typhoid fever was assigned, in advance, as the special subject of discussion at one of the afternoon meetings.[1]

Discussion was directed to a consideration of the following debatable questions:

(1) Does the term typhoid fever properly include all the varieties described by observers; or are there other, still undifferentiated, continued fevers commonly grouped under this head?

(2) Is typhoid fever always the product of a specific contagium from a pre-existing case; or may it arise, *de novo*, from filth-fermentation?

(3) What part is played by micro-organic ferments in the causation of enteric fever?

(4) Is there a disease of the lower animals transmissible to man as typhoid fever?

(5) What media of causation or transmission of typhoid fever are to be guarded against in public or private sanitation?

(6) What are the complications and sequelæ properly associated with typhoid fever?

(7) What are the indications for treatment, and are relapses or untoward complications favored by some antipyretic measures?

The first speaker thought we were justified in speaking of a specific exanthematous fever, with local lesions in the intestinal glandular apparatus, apparently developed only from changes which took place in the excreta of a previous existing case, and which might, until a clearer idea of the pathology was obtained, be entitled enteric fever; that one attack, as a rule, af-

[1] See page 364 of the Journal.

forded immunity for the future; that adynamic fevers occur in isolated rural districts, where no connection with a previous case is discoverable; and that such fevers, resembling typhoid or enteric fever in the clinical history, could be traced to filth-fermentation.

Dr. E. G. Janeway thought that a form of continued fever not due to typhoid poison is encountered; he has found very few recorded cases in which it appeared that the disease had developed in entirely isolated surroundings, such as seemingly to preclude the possibility of contagion derived from another case, and in none, he thought, had the proof been altogether beyond question; whilst admitting a germ as the original cause of typhoid fever, he was willing to entertain the possibility of a spontaneous origin, but he could not admit that it had been proven beyond doubt. He rejects the term typho-malarial, very properly, as we think, preferring typhoid fever with malarial complication.

Dr. Biggs, of the Carnegie Laboratory, accepts Eberth's bacillus as a true bacillus of typhoid fever. Dr. Salmon, of the Government Service at Washington, thinks there is no reason to suppose that there is a specific disease in animals which produces a specific disease in man, attributable to this bacillus typhosus.

These are important points, some of which the last few years have tended to elucidate; whilst, in regard to others, we can only reason from analogy, and await an expansion of knowledge before having the means of reaching positive conclusions. The discussion, however, brought out very fairly the best views of the present day.

THE INDEX-CATALOGUE, VOLUME EIGHT.

The eighth volume of the Index-Catalogue of the Library of the Surgeon-General's office which has just appeared, carries the index to Medicine (Naval). It includes 13,405 author titles representing 5,307 volumes and 13,205 pamphlets. It also includes 12,642 subject titles of separate books and pamphlets, and 24,174 titles of articles in periodicals.

This interesting volume contains an index of the literature of stone from lithectasy through litholapaxy, litholibia, litholysis and lithontriptics to lithotrity.

Subjects classified under the head *Massachusetts*, are numerous, and contain reports from various public institutions and hospitals, charitable societies of all sorts, etc.

Two hundred and eighty-seven pages are occupied by subjects classified under the general head of *Medicine*, which is interrupted at *Naval Medicine*, by the close of the volume, so that the same general head must occupy a large space in the ninth volume when it appears. Abuses and errors of, and satires on Medicine, cover nearly four pages. Anecdotes, curiosities and facetiæ of medicine is a sub-head which covers even more space. Under this heading occurs Sir Kenelm Digby's "A late discourse made in a solomne assembly of nobles and learned men at Montpellier, in France — touching the cure of wounds by the powder of sympathy; with instructions how to make the said powder. Rendered faithfully out of French into English by R. White. 2d edition, London. 1658," and a seventh German edition of the same published at Ratzeburg, 1718; and Fludd, R. "Answer to M. Foster; or the squezing of Parson Foster's sponge, ordained by him for the wiping away of the weapon salve. Wherein the sponge-bearer's immodest carriage and behavior towards his brethren is detected: the bitter flames of his slanderous reports are, by the sharp vinegar of truth, corrected and quite extinguished, and lastly the virtuous validity of his sponge in wiping away of the weapon salve is crushed out and clean abolished, London, 1631;" "Life (The) and adventures of Don Bilioso de L'Estomac. Mathews (R.), A pretious pearl in the midst of a dunghil, being a true and faithful receipt of Mr. Richard Mathews pill. Presented to the world by Mrs. Anne Mathews amongst many sad complaints of wrongs done to her and the commonalty and her deceased husband. London, 1663."

Military medicine is presented under historical divisions so that we have the Napoleonic wars as a subsidiary heading which opens with a book by Beaufré, "A treatise on the effects and properties of cold; with a sketch, historical and medical, of the Russian Campaign;" and contains among other interesting material a description by Deputy Inspector-General Longmore, of a series of water-color drawings, executed by Sir Charles Bell, illustrative of wounds received at Waterloo.

The War of the Rebellion occupies of course considerable space. The previous wars of the United States made but small contributions to medical literature.

The present volume ought to mark the completion of the first half of the work, though we venture to predict that the growth of the library will extend the second half to more than eight volumes.

A NEW METHOD OF TREATING SEA SICKNESS.

Dr. W. Skinner has written to the *Semaine Médicale* his experience in the treatment of sea sickness.

He regards this affection "as the expression of certain purely functional or dynamic disturbances of the organism." "Some of the symptoms (the abnormal compressibility of the pulse, the oliguria, the chilliness of the extremities, the great pallor of the skin, and certain signs of cerebral and bulbar anæmia) indicate a general fall of the arterial blood pressure." The cause is to be found in paralysis of the vasomotors; "the starting point is probably a reflex inhibition coming from the sensorium (sight, hearing), or from the nerves of the abdominal organs." These organs, he says, are doubtless slightly contused and stretched by the rolling and pitching of the ship, and the terminal fibres of the sympathetic sensory nerves

are irritated thereby and provoke inhibition in the vaso-motor centres.

Acting on this theory, the writer prescribes certain vaso-motor stimulants, the chief of which are strychnia, atropia, and caffeine. The two first are given together, the latter separately. The caffeine is never given simultaneously with the other two medicaments.

He employs the hypodermic method, for obvious reasons. One milligramme of atropine and the same quantity of strychnine are dissolved in about one cubic centimeter (a hypodermic syringeful), of peppermint water and injected. His formula is as follows:

Sulphate Atrophine } Sulphate Strychnine }	55	0.01
Distilled Water of Peppermint	40.00	M.

One gramme of this solution contains one milligramme of each of the alkaloids. The solution ought to be frequently renewed. The quantity of strychnine may be increased to double, and that of atropine may be lessened, according to the indications of the case. The dose for children may be one-half or one-fourth that of adults. The reporter has seldom found it necessary or deemed it prudent to repeat the injection the same day, although in very bad cases one injection may be given in the morning and one in the evening.

In the case of an infant of two-and-a-half years, Dr. Skinner injected one-sixth of a gramme of the above solution; the relief was prompt and lasting. A boy of six years of age was cured of his sea sickness by one-quarter of a gramme of the solution!

In the great majority of cases instant and permanent relief from the nausea and vomiting is stated to follow one injection of the solution. Thirty-nine cases, in which this treatment proved efficacious, are reported!

Caffeine, also administered subcutaneously, is said to give excellent results. Its action is a little slower than that of the other alkaloids, and it is not quite so certain. The following formula is the one which is recommended:

Caffeine	4 grammes
Salicylate of Soda	3 grammes
Distilled water q. s., to make ten cubic centimetres,	M.

Each cubic centimeter (about a syringeful) contains forty centigrammes (about seven grains) of caffeine. Dr. Skinner reports several cases where, by means of this prescription, patients were enabled to make comfortable voyages.

Even the terrors of possible strychnine poisoning we do not doubt would seem trivial to some sufferers among those who go down to the sea in ships.

ANNUAL REPORT OF THE BOSTON CITY HOSPITAL.

THE twenty-third annual report of the trustees and Superintendent of the Boston City Hospital, is for the calendar year 1886, but for some unexplained reason made its appearance seven or eight months after the close of the year. It contains the usual items of interest and indicates, so far as such reports go, that the hospital is doing the work for which it is designed in a creditable and successful manner. The routine of such an institution, with its six hundred inmates, can scarcely be expected to proceed at all times without some degree of friction, but we believe the condition, the administration and the work of the Boston City Hospital will, in general, compare very favorably with those of any similar large metropolitan institution, wherever situated and with those of most hospitals under the control of private corporations, and we hope should changes arise, they may always be of a nature to improve upon rather than to threaten the continuance of such a record. If the weak points of the hospital were to be sought for, probably the insufficient accommodation for the out-patient department and the somewhat inadequate means for heating might justly be alluded to.

The total expenditures for the period included in this report were $177,306.27. The average net cost per patient each week was $7.52, against $7.64 last year and $8.39 two years ago. The income from paying patients was $32,407.57.

During the year 5,368 patients were treated in the wards, 13,614 as out-patients, making a total of 18,982 who received treatment in the various departments during the year. Of 6,086 persons examined for admission 1,040 were rejected, which is proportionately less than the previous year. Of the number rejected nearly one-third were nominal applications, they being subsequently treated as out-patients and obtaining such benefits as seemed suited to their cases. Nearly one-third were unsuitable, being either wholly incurable or the victims of intemperance, improvidence, or malingerers; of the remaining third only 62 were rejected for want of room out of 6,086 applications. Of the 19 daily average of applicants, 2 were rejected and 17 admitted. The largest number admitted in any one month was 497, in July, and the smallest, 352 in January.

The largest number of patients on any one day was 391, against 365 last year; the smallest was 311, against 265 last year. The daily average was 344, which is 29 more than last year, and 58 more than two years ago. The average length of stay was 23.3 days.

The number of patients admitted with accidental injuries was 881. Of all patients admitted 221 died within 48 hours after admission. The rate of mortality was 11 per cent. If from the total number of deaths we deduct those brought to the Hospital in a dying condition, the annual mortality is reduced from 11 to 7 per cent. The capacity of the wards remains the same as last year, 425 beds, and, with rare exceptions, has been found sufficient, except in the wards for contagious diseases.

In the Out-patient Departments 13,614 persons made 41,451 visits, which, distributed among the week-days of the year, made an average daily attendance of 133 out-patients. The largest attendance was 4,764 in the month of August, being a daily average of 183; the smallest was 2,246 in December, and the daily average was 83. In the nine departments for treating out-patients 17,460 visits, or 42 per cent. of the

whole, were surgical. Nine thousand nine hundred and thirty visits, or 21 per cent., were to the Eye Department, and the remaining 37 per cent. were distributed among the various other services.

The tent service in connection with the hospital, which affords fifty-six beds, was in active use and of the utmost advantage, especially for the most serious surgical cases, during the summer months. Its maintenance is comparatively inexpensive, and experience has amply demonstrated the advantages of treatment under these conditions; moreover, opportunity is thus afforded of vacating and renovating in turn the permanent wards.

Since the publication of this report we understand the tent service has been further extended, so that medical patients share in some degree in its benefits.

The training-school for nurses, at the close of its ninth year, continued to work very efficiently, and numbered seventy members. The new Nurses Home gives satisfaction.

The trustees state that the per capita cost of carrying on the Hospital has been brought to the lowest point, $7.50 a week, which is compatible with the maintenance of a high standard of service and preservation in a large metropolitan hospital devoted to acute diseases and surgery. The trustees also recommend to the Mayor and City Council a further appropriation of $16,000, in addition to a sum of $19,000, now on hand, to meet the necessities of the erection of a suitable out-patient building. There are, certainly, less desirable ways of spending the taxpayer's money than in providing for the decent care of the sick poor of the city.

MEDICAL NOTES.

—The Rev. Dr. Maynard, a well-known lecturer on European Travel, a passenger on the *Alesia*, the New-York-bound Italian ship, on which occurred the recent outbreak of cholera, writes, in the daily press, that the death of the first victim, a young Neapolitan, was announced to be due to heart disease. He says: "There was, at the time, no ground for supposing otherwise, and yet, in some unaccountable way, all on board became seized with a misgiving. The funeral of the Neapolitan was a sad and impressive sight, and, if it was possible, it increased the general dejection. Previous to this we were a gay company, the Italian emigrants particularly so. The discomforts attending an emigrant voyage seemed to have no effect upon their spirits. They chatted and laughed, and sang and danced, all day long, and well into the nights, which were made more pleasant by moonlight. But, from the time the Neapolitan died, not a sound of mirth was heard. The dancing was ended. Not a note was sung. I have no doubt that the condition of mind of these people had a good deal to do with the swift headway which the disease made after it began its work. I never saw such a complete surrender to misfortune as these people made. They made no struggle with fate, but sat or moved about listlessly and lifelessly, and seemed actually to invite death by their dread of it. Strange to say, the disease first struck the Neapolitans, and the proportion of the stricken among them was greater than among those from Palermo, who imparted the disease."

— Inquests have been held in England, during the past week (*British Medical Journal*, September 24th), on the bodies of three children, who, bitten by rabid dogs, died from hydrophobia. Two of the victims, aged respectively eight and nine years, were bitten, in the suburbs of Liverpool, on August 30th. The rabid animal not only attacked other dogs, but several persons were bitten by it, and it was only prevented from doing further mischief by the bravery of Mrs. Atkinson, who, in her successful efforts to protect three children, was herself badly bitten. She has gone to Paris to be treated at the Pasteur Institute. We have already referred to the death of the Kirkham child at Lancaster, which occurred almost immediately after his return from a treatment by Pasteur, whither, it seems, he was accompanied by two other children also bitten, but whether on the same date, we do not learn. Kirkham was bitten July 18th, started for Paris seven days later, remained there a month, had his first symptoms the day of his return, and died two days later.

— The *Medical Register*, of Philadelphia, having stated that the editor of the *Medical News* was the author of the dispatches sent from Washington to the *Philadelphia Press* in regard to the International Medical Congress, the managing editor of the *Press* issues a circular, in which he states that the editor of the *Medical News* was not the author of the dispatches in question, and that he was not in any way responsible for them. They were sent from Washington by two regular correspondents of the *Press*, and he finds, upon inquiry, that the identity of the writers was absolutely unknown to Dr. Hays, who, he adds, is at the present moment quite unknown to him, save by name.

NEW YORK.

— Fifteen of the passengers of the *Alesia* have died of cholera since the vessel arrived, and still there are nine cases of the disease in the Swinburne Island hospital; all of whom, however, are said to be doing well.

— After three trials Dr. C. Fayette Taylor has won a verdict of $12,000 against the elevated railway for damage to his private hospital by the road, which runs on two sides of it.

— Mr. Cornelius Vanderbilt has added to his other benefactions a handsome and completely fitted up building, situated in the immediate vicinity of the Grand Central Rajlway Depot, for the accommodation and enjoyment of railroad men. On the first floor are a library containing six thousand volumes, a reading-room, social room, and bath-rooms. On the second floor is a large hall for lectures and entertainments. On the third floor is the restaurant and recreation room, completely fitted up with lounges, and here the men can always obtain hot coffee free of charge. On the top floor is a large room fitted up

with brass bedsteads for the use of railroad men staying in the city over night. The building was formally opened on Monday evening, October 3d, and on this occasion the principal address was made by Mr. Chauncy M. Depew, who, in the course of his remarks, said: "It has been rightly claimed by our Christianity that it infinitely excels all religions and civilizations in humanity. Until Christianity came you never found men looking after the weak and helpless, the sick, aged and infirm. It has created hospitals, asylums, schools. It is the glorious Christian spirit which expands civilization. When the money of the many has gone into the corporation, when the many represented in that corporation cannot know those who work for them, and those who work for the corporation cannot know or meet those by whom they are employed, the strain of relations becomes so tense that, unless some avenue of mutual approach be found, we are upon the brink of those social revolutions, those labor problems, those distinctions of class, that are at once the terror and the sum to be done by the sociologist, the preacher, and the statesman of to-day. This building, with its appointments and completeness, stands now as one of the many signs pointing out how the chasm, which never shall be bloody, can be bridged, and we, of all conditions of life, recognize in our common humanity, all our responsibilities to one another."

— The Board of Education decided at its last meeting to give Public School Trustees the option of testing manual training. The subject has been a long time under consideration and the Committee on Course of Study and School Books, gave the matter careful and deliberate investigation, the result of which was embodied in a report submitted last June, and discussed at meetings since then. The initiation is provided for in the following way: On application of any Board of Trustees to the Committee to introduce manual training into any school, the committee may authorize the substitution in such school of the course of study and provisions prepared by them in place of the usual course of studies, and the proper committees shall authorize the expenditures necessary therefor, provided that, until further action is taken by the Board, such course shall not be introduced into more than six male and six female grammar schools, and the primary departments and schools connected with them. A mixed grammar school shall be considered, as to this provision, as one male and one female grammar school. In no case are the studies of German and French to be interfered with. The test of the plan will, it is estimated, cost $13,000.

Miscellany.

THE DEAD FAILURE, LIMITED.

Mr. Edward Garraway, in the *Edinburgh Medical Journal* for August, in an amusing, but most interesting paper, sets forth his intention to establish a new medical journal, for which it seems to us the sole remaining unoccupied niche in medical journalism remains open. He says: "The title of my venture would be 'The Dead Failure, Limited.' Ignoring the maxim that 'Dead men tell no tales,' my book would be made up of nothing but dead men's tales.

"The journals of the day teem with the triumphs of medicine and the exploits of surgery. Everybody records his successes and narrates his victories, till at length one begins to wonder how it comes about that anybody ever dies. People, nevertheless, do die, apparently from sheer perversity, or, as our transatlantic brethren might more pertinently put it, from 'pure cussedness.' Certainly, if we believe, it is no more the fault of the medicine men of the present generation than it was in the days of the celebrated Dr. I. Lettsom, who, you may remember, in allusion to his unhappy patients, is said to have written:

> 'I physics, bleeds, and sweats 'em;
> If after that they chance to die,
> It's not my fault — I. Lettsom.'

Now 'The Dead Failure, Limited,' is intended to search out 'the reason why.' It will have nothing to do with cures and recoveries. Defeats and disappointments, whether brought about by negligences and ignorances, sins of omission or commission, errors in judgment, or deficiency in tact — no matter from what cause — unsuccessful cases will alone be admitted. Ah! what rocks, what shoals, what quicksands we might avoid, if every man would raise a beacon where he has suffered shipwreck, instead of glorifying himself, as is his wont, when he has ridden through the storm, or favorable gales have wafted him into port! One prominent and valuable feature of the contributions would be their emanating from the Nestors only of our profession, the most diligent inquiries amongst young practitioners serving but to show that *they* never *do* meet with failures, and never make mistakes."

Following this are some "specimen pages" from such a journal, describing, for instance, errors in the diagnosis of eruptive diseases, especially small-pox.

Of the other instances of mistaken diagnoses we have room for but one, namely stone in the bladder.

"Who," asks our author, "cannot diagnosticate stone in the bladder? Who does not know the characteristic 'clink'? But does everybody know that the clink may be there without the stone? A young lady got retention of the urine. Of course in young ladies the element hysteria has always to be taken into account, and one should be slow to introduce the catheter for the first time, for who can say where or when such a proceeding may end. All other measures failing the patient must needs be relieved. On passing a silver catheter, a click was heard and a concussion felt as its point entered the bladder. Not hastily convinced, I waited till the next day, when the retention recurring, I audibly and sensibly struck the calculus. The young lady's friends were apprised of the nature of the malady and of my hope that without any operation the stone might be removed. Dilatation of the urethra was gradually effected until the forefinger could be swept over the whole internal surface of the bladder, and behold that viscus was empty. Then, and not till then, did it occur to me how often, in turning off the water at my surgery tap, I had heard and felt precisely the same concussion. The conditions were analogous. As the catheter entered the full bladder, the urine came down the tube with a rush, giving a

shock as it impinged upon the head of the stillette at the other extremity. Some balm was dropped upon my wounded pride by afterwards hearing from my friend, Professor Lund of Manchester, that he had been similarly deceived, and went so far as boldly to cut into the bladder, and more boldly and bravely still, to publish his mistake in his valuable Hunterian lectures of the following year.

"Well, now for the sequel, irrelevant, perhaps, but amusing and edifying withal. Incontinence, you will say, resulted from my uncalled-for proceeding. Nothing of the sort. That young lady and I and the catheter kept company for a year and a half; at first twice a day, after a time once, then every other day, every third day, and so on, till at the end of sixteen months I managed to get her sent away from home, retention at that time recurring but once a week; and it was understood that every Tuesday morning I should travel eighteen miles by rail and three across country to the relief of my patient, take luncheon, and return.

"What confounded humbug! some will exclaim. Well, it was confounded humbug, but assuredly not of my creating. Very early in the case I protested, at length became obdurate, refused to pass the instrument, leaving the unhappy girl for two days and two nights. At the end of this period she plunged into a convulsion, during which the urine escaped, and from which she emerged with paralysis of the right arm — hysterical, of course — but paralysis nevertheless. The friends scarcely forgave my inhumanity, and the catheter routine went on as before."

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 1, 1887.

Deaths reported 2,373: under five years of age 912; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 510, consumption 422, acute lung diseases 198, diarrhœal diseases 166, diphtheria and croup 151, typhoid fever 76, malarial fevers 46, scarlet fever 29, cerebro-spinal meningitis 17, measles four, erysipelas three, small-pox (New York) one. From malarial fever, New York 15, New Orleans 11, Brooklyn eight, Baltimore four, District of Columbia three, Milwaukee and Nashville two each. From scarlet fever, Brooklyn eight, New York and Boston seven each, Baltimore two, Philadelphia, Milwaukee, Cambridge, Fall River, and Fitchburg, one each. From cerebro-spinal meningitis, New York and Fall River four each, Lynn three, Philadelphia, Boston, District of Columbia, Pittsburgh, Worcester and Holyoke one each. From measles, New York three, Philadelphia one. From erysipelas, Baltimore two, Brooklyn one.

In the 28 cities and larger towns of Massachusetts with an estimated population of 1,131,336, the total death-rate for the week was 19.26 against 23.31 and 22.04 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending September 17th, the death-rate was 18.0. Deaths reported 3,186: infants under one year of age 971; acute lung diseases (London) 142, diarrhœa 296, scarlet fever 116, whooping-cough 84, fever 48, diphtheria 37, measles 34, small-pox (Sheffield nine, Liverpool and Cardiff one each) 11.

The death-rates ranged from 15.0 in Derby to 27.0 in Preston; Birmingham 18.5; Bradford 23.0; Hull 17.0; Leeds 17.8; Leicester 17.5; Liverpool 18.3; London 15.7; Manchester 25.8; Newcastle-on-Tyne 21.6; Nottingham 18.4; Sheffield 20.1; Sunderland 22.1.

In Edinburgh 16.3; Glasgow 19.2; Dublin 34.3.

The meteorological record for the week ending October 1, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Oct. 1, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 1, 1887, TO OCTOBER 7, 1887.

CARTER, E. C., captain and assistant surgeon. Leave of absence further extended fifteen days. S. O. 231, A. G. O., October 4, 1887.

CABELL, J. M., first lieutenant and assistant surgeon. Relieved from further duty in connection with the competition of "Team of Distinguished Marksmen," at Bellevue Rifle Range, to take effect October 1st, and will return to his station, Fort Omaha, Neb. S. O. 95, Department of Platte, September 27, 1887.

CABELL, J. M., first lieutenant and assistant surgeon. Will be relieved from duty at Fort Omaha, assigned to temporary duty with Battalion 6th Infantry in the field, October 1, 1887.

BORDEN, W. C., first lieutenant and assistant surgeon. Will be relieved by officer commanding troops, upon arrival of Assistant Surgeon Cabell, and will return to his station at Fort Douglas, Utah. S. O. 98, Department of Platte, October 1, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 8, 1887.

MARTIN, WM., assistant surgeon. Detached from Hospital Norfolk, and granted sixty days' leave.

BATES, N. L., medical inspector. Detached from Naval Dispensary, and to Examining and Retiring Board.

PRICE, A. F., surgeon. Ordered to the Naval Dispensary, Washington, D. C.

WAGGENER, J. R., surgeon. Ordered to the Receiving Ship "Minnesota."

FITZSIMMONS, PAUL, surgeon. Detached from "Minnesota," and to "Morion," 15th October.

ATLEE, LOUIS W., assistant surgeon. Detached from Receiving Ship "Vermont," and to the "Morion," 15th October.

RUSH, W. H., passed assistant surgeon. Detached from coast survey Steamer "Blake," and to the Navy Yard, New York.

BERRYHILL, T. A., assistant surgeon. Detached from "Minnesota," and to the "Blake."

DRENNAN, M. C., surgeon. Detached from Naval Academy, and wait orders.

SOCIETY NOTICE.

FIFTEENTH ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.—The American Public Health Association will meet at Memphis, Tenn., Tuesday, November 8th, at 10 o'clock, A.M., and continue four days. The meetings will be held in Young Men's Hebrew Hall. The Executive Committee have selected the following topics for consideration at said meeting: I. "The Pollution of Water-Supplies." II. "The Disposal of Refuse Matter of Cities." III. "The Disposal of Refuse Matter of Villages, Summer Resorts, and Isolated Tenements." IV. "Animal Diseases Dangerous to Man."

DEATHS.

Died in West Roxbury, Mass., October 3, 1887, George Otis Allen, M.D., M.M.S.S., aged forty-eight years.

Died in Boston, October 8, 1887, David McCaire Parker, M.D., M.M.S.S.

OBITUARY.

GEORGE OTIS ALLEN, M.D.

Dr. George Otis Allen died suddenly at his residence in West Roxbury, October 4th. He was born at Norton, October 25, 1838. He spent one year in the medical department of Bowdoin College, Brunswick, Me., and then became a member of the Harvard Medical School. Soon after the breaking out of the civil war he received the appointment of medical cadet in the army, and spent a year in Louisville, Ky., in that capacity. He then returned to the Harvard Medical School to finish his studies. After being graduated he was appointed volunteer assistant surgeon in the navy in the Mississippi squadron. At the close of the war he was for some time in the Naval Hospital, Chelsea, and was also on the "Franklin," the flagship of the European squadron, for three years. On his return to this country he was again stationed at the Naval Hospital, Chelsea. He resigned his position in the navy, 1872, to enter into private practice, and had lived in West Roxbury since 1874. He had been a member of the Massachusetts Medical Society since 1866. .

RICHARD QUAIN, M.D., F.R.C.S.

Dr. Richard Quain, the editor of "Quain's Dictionary of Medicine," and well known as a physician and writer on medical subjects, died in London, England, September 16, 1887. He was born in Mallow, in 1816, and became an articled pupil to a surgeon-apothecary at Limerick. At the age of twenty he went to London and entered University College. Distinguishing himself in the classes, he was appointed house-surgeon to the College Hospital, and subsequently house physician to the same institution. He was elected a Fellow of University College in 1843, a member of the Royal College of Physicians in 1846, and a Fellow of that College in 1851. His life was full of professional cares and honors. He was one of the founders of the Pathological Society and was a member of a great number of learned societies. The "dictionary," above referred to, was published in 1882, and is the standard work of its kind in the English language. Among his many other writings was a monograph to the Royal Medico-Chirurgical Society, in which the true nature of fatty degeneration, especially in connection with the walls of the heart, was first described.

Original Articles.

THE IMPORTANCE OF RE-EXAMINATIONS AS TO THE ACCURACY OF VISION OF RAILROAD EMPLOYEES AND MARINERS.

BY HENRY W. WILLIAMS, A.M., M.D.,
Professor of Ophthalmology in Harvard University.

After the enactment of the law requiring that tests should be made as to the accuracy of perception of colors, and as to the sharpness of vision of mariners and of railroad men, who are required to readily distinguish signals, obstructions, or other intimations of danger, the railroad officials of Massachusetts manifested a willingness to at once comply with the demands of the Statute, so far as a first examination of their employees was concerned, although the managers of, at least, one road, seem to have deemed it sufficient if danger-signal flags or lanterns could be distinguished from those denoting safety, when displayed, one after another, at certain distances — a test which all experts know to be fallacious, as it *does not* prove an ability to distinguish signals when unexpectedly shown, or when they are soiled, or faded, or dimmed, since, especially in these circumstances, those who are color-blind readily mistake one for the other.

These Statutory examinations give a result similar to those obtained on a very large scale in this and other countries, showing that, as an average, about four per cent. of males have dangerously imperfect ability to distinguish red from green, the colors of most frequent use in signalling. They also demonstrated what is of yet more grave importance, that, in a still larger proportion, defects of visual acuteness existed in men who were supposed by others, and often by themselves, to have good sight.

These demonstrated facts, and the occurrence of such instances as the running over and killing of a brakeman holding a red danger-signal on the track in front of his train, by an engineer who was afterwards found to be color-blind, would seem to be sufficient to satisfy the observant officers of railroads, and owners of ships, of the necessity of the required tests for all entering their service who were to fill positions where prompt recognition of signals, and quick and accurate perception of objects, is required; and this not only as an imperative duty towards the persons whom they undertake to transport in safety, but also as being necessary as a safeguard for their property, in avoiding the enormous costs of accidents, and the exemplary damages which would be awarded where it was proved in court that an accident had resulted from the color-blindness or defective sight of an employee.

As regards the men themselves, their rejection, if found to be visually defective, cannot be reckoned as a hardship, since it is especially for their advantage that they should turn to other avocations, rather than assume positions which imperil their own safety, as well as the lives and property of others; or, at least, that they should be assigned to duties for which their natural or acquired visual defects do not disqualify them.

The importance of the elimination of incapacitated men from the marine and railroad service, as shown and insisted on, especially, by Professor Holmgren, of Sweden, and Drs. Thomson, of Philadelphia, and Jeffries, of Boston, has lately been brought prominently before the public by a riotous resistance to examination, as to their visual capacity, by the 42,000 employees of one of the large American railroad corporations; which, for a time, threatened a total suspension of traffic upon this road. As regards this event, Dr. William Thomson, who acted as an expert in deciding the controversy, says (*Medical News*, August 13th): "The conflict is nearly over, since demonstrations of the optical defect in engineers, made before a committee appointed by the employees, have satisfied them of the propriety of the testing, and that the safety of the public demands the removal of all color-blind persons from positions where their optical defect might be the cause of distressing accidents. In the recent demonstration, I was able, at my office, to show that an engine-man declared a red danger-signal, made by placing red glass in front of a large gas-light, at the distance of two feet away, to be a green glass. He was not only unable to distinguish a red from a green flag within six feet, but he failed to classify the flags, white, red, green, and blue, properly, even when allowed to take them in his own hands." Instances such as these cited are constantly met with by ophthalmological experts.

Attention has also lately been called to this matter by articles in some of our newspapers, referring to the disturbances above mentioned; giving certain statistics of the results of examinations on the Pennsylvania Railroad, which seemed to be misleading, as being inconsistent with those previously obtained on this road, and with the usual average of imperfect color-perception and of visual defects, as observed in various European nationalities.

These statistics were as follows:

Total number examined on lines east of Erie, . .	25,158
Color blind, ...	481
Defective vision	661
Defective hearing	158

In reply to questions regarding these tables, Dr. Thomson writes to me as follows:

"In 1884, the examinations of men who had to do with signals amounted to about 13,000. When the total increases to 25,000, and comprises many men coming into the service, the percentage must be smaller. The apparently small percentage of color-blind in this table may be ascribed to the non-application of men who know their deficiency, and to the fact that men in the service knowing their defect, would leave the road before examination, and thus escape detection, and be enabled to gain employment on other roads, where no examinations are required. New men would present a small ratio of those below the standard, since men conscious of color-blindness or poor sight would not apply."

There is reason to believe that, even in Massachusetts, the provision of the Statute which calls for re-examination of employees at stated intervals has been but negligently fulfilled. Admitting that those once found to have good power of distinguishing colors seldom lose this ability, and scarcely require as frequent re-examinations, the same is not true as to other visual deficiencies. Sharpness of sight is not a fixed quantity, and lessening of visual acuteness may occur at any time, and from many and various causes, in those whose sight had been found to be perfect at a former examination. Normal changes of visual power occur at different ages, and, although these, as well as some abnormal conditions of the refraction and accommodation of the eye, may, perhaps, be remedied by the use of glasses, yet the necessity of wearing glasses

is, in itself, an important disability, inasmuch as spectacle-glasses are liable, especially in cold weather, to be suddenly obscured by a puff of steam or smoke, or by fog in the atmosphere, and the wearer is thus rendered *pro tempore*, and perhaps, again and again within the space of a few minutes, virtually blind, until the glasses can be removed and wiped. But vision may also be gravely impaired, at first gradually, and perhaps, nearly imperceptibly to the person himself, by the development of cataract, of Bright's disease, of various slowly-advancing brain lesions, etc., as well as by numerous forms of disease of the internal parts of the eyes not discoverable by external inspection. These constitute a grave danger, especially as the afflicted person, even if conscious that he sees less distinctly, clings to the hope of an improvement, and is reluctant to give up his means of support.

Doubtless the omission to comply fully with legal requirements, and the neglect of self evidently necessary precautions, has arisen from inattention in a matter which is even yet a comparatively new subject to the railroad authorities; but the frequent revelation of cases of greatly depreciated sight in employees whose vision had been found to be good no longer ago than two years, proves the need of vigilance to *discover* these defects by re-examination, before they become a source of disaster. If scrupulous exactness should ever be insisted on, it should be in the use of every precaution where the safety of great numbers, or of vast property, may depend on the clear vision of one man.

What can be said of the false economy and culpable negligence existing in some States, where, because no Statute compels examinations as to the perfection of sight and hearing of employees, the managers of railroads feel justified in dispensing with them. They thus incur the risk, not only of having the usual average of about four per cent. of color-blindness, and ten per cent. of imperfect sight, among their employees, but also of making their roads asylums for many discarded men, who have been elsewhere tested and found wanting in the essential qualifications of good vision.

A not unimportant element of this question is the ease with which complete security can be obtained. As stated by Dr. Thomson: "The officers needed a system that could be employed on each division of the road, quietly and confidentially, and at the convenience of the men, without compelling them to lose much time. These and other considerations led me to the invention of an instrument for an examination of the color-sense, which could be used by any intelligent, instructed official, and a record of the examination permanently kept for the information of the officers, and as a guide for any expert to whom the road might wish to refer any doubtful cases." This system has been in use for more than five years on the Pennsylvania Railroad, with its now 7,000 miles of track, and over 100,000 employees.

— A case is recorded by Dr. C. R. Eckhardt of carcinoma uteri (diagnosis established by histological examination) in a virgin, aged nineteen. It is said that thus far only three cases have been recorded of this disease occurring before the age of twenty. The growth was removed with a galvano-cautery snare by Fränkel.

A CASE OF ACUTE RED ATROPHY OF THE LIVER.[1]

BY A. F. HOLT, M.D., OF CAMBRIDGE.

At one o'clock in the morning of November 13th, Mrs. M. came to the police station to make a complaint against her husband for beating her. She claimed that he had choked her until she was unconscious, that while he held her on the floor, he jumped on her chest on his knees, and it was only with the greatest difficulty that she escaped from him and ran to the police station, a half-mile or more away, clad only in her night-dress and stockings. The husband was arrested, and at the trial, the following morning, the wife testified that her husband had only held his hand over her mouth. The wife, after the assault, went to the house of her mother, instead of returning to her own home, and there she remained until her death, nine days after. For the next four days, she was about the house and the street, and a part of the time, at least, was under the influence of liquor. During these days, she called on Dr. Church once for examination as to the injuries which she had received from the assault by her husband. At this interview, she complained of soreness in the right chest. Physical examination showed nothing, except a few scratches and a small black-and-blue spot near the sternum. Her pulse and temperature were normal.

The afternoon of the 19th, Mrs. M. was seen by Dr. Bryant, the city physician, at the office of the Overseers of the Poor, and from him I obtained the following history: Age, twenty-nine years; there is a black-and-blue spot about the left eye, whites of both eyes jaundiced, and the skin of the chest and abdomen is yellow. She is constipated, has a slight cough, and complains of great weakness. One gramme of calomel was ordered, to be taken at once.

November 21st. Saw her at her mother's house at 10 o'clock, A. M. She was in bed, and very restless. Hands and feet cold, and the pulse 108; complained of constant nausea, and had vomited a great many times since last seen. Liver-dulness about normal; bowels moved slightly yesterday. One gramme of calomel, to be given in two doses; mustard to stomach, and ice-pills.

4 o'clock, P. M. Has not vomited since morning; has not spoken since one o'clock. Bowels have not moved. She is unconscious, but very restless. Brandy and milk every hour, and an injection of warm water.

At 7 o'clock, P. M., saw the patient, with Dr. Church. She is still very restless. No discharge from the bowels. Temperature slightly subnormal, pupils respond to light, slight, crepitant râles at the base of both lungs, and *the liver-dulness has disappeared.* Pulse rapid and feeble; has passed no urine for twenty hours. Hands and feet and end of nose cold; skin everywhere deeply jaundiced. The patient continued to fail, and died at one o'clock the following morning, or about eight hours after the doctor last saw her. The claim was at once made that death was the result of injuries received at the hands of her husband, and he was arrested to await an investigation. The autopsy was made thirty hours after death, and the following is the record:

Body fairly well nourished; pupils a little dilated. There is a black-and-blue spot under the left eye, but

[1] Read at a meeting the Boston Society for Medical Observation, May 2, 1887.

no other external marks of violence. Skin everywhere of a bright-yellow color. On opening the great cavities, the tissues are seen to be of the same yellow color. The stomach is greatly dilated, and it and the small intestine are distended with gas. On removing the sternum, on its upper third there is seen a large, red spot, caused by the infiltration of blood generally. The tissues in the anterior mediastinal space are also infiltrated with blood. The pericardium is normal in appearance. The right side of the heart is moderately full of blood. There are a number of hæmorrhagic spots beneath the pericardium, along the line of junction of the right auricle and the right ventricle. Two or three of these are of the size of the finger-nail, the others are smaller. Section through one of these spots shows the clot to be of a yellowish color, firm, and nearly the third of an inch thick. The right auricular-ventricular opening admits three fingers. The left side contains a small, black clot. The mitral opening admits two fingers. The valves of the organ are healthy, and the cavities are of a normal size, and the walls of normal thickness. The muscular substance is of a yellow color, and the cut surface appears opaque. Microscopic examination shows this tissue to be very granular, and also, that it has nearly lost its striated appearance.

The left lung is slightly adherent at the top. It is very heavy, and its blood-vessels are full of black blood. A quantity of frothy, bloody fluid can be squeezed from the cut surface. The bronchi are also partly filled with frothy fluid. The right lung is like the left, except it is not adherent, and a frothy fluid flows from the cut surface. In the pleura, covering the chest along the spine from the second to the sixth ribs, on the right side, are a number of black spots, some of which are more than an inch square, but irregular in outline. Section shows these to be due to an effusion of black blood beneath the pleura. Also, beneath the pleura, covering the diaphragm of the right side, there are a number of spots of the same character. The pleura of the left side is everywhere of the same color, and clear and glistening. The tissues about the trachea are infiltrated with blood. Its mucous surface is smeared over with a red, frothy mucus. The mucous membrane of the œsophagus is of a pale, grayish color.

Spleen large, of a uniform bluish color, and a little soft. Left kidney of a bluish color, capsule strips off readily, the cortical portion a little thicker and a little paler than normal. Right kidney like the left, except the pelvis is a little dilated, and the loose tissues about it are infiltrated with blood. Bladder contains about eight ounces of urine. Vagina rather large, and its walls are flabby. The mucous surface is a pale, reddish color.

The os uteri is irregular in outline, and it has two deep fissures, one extending wholly across the neck, the other part way. These are covered with mucous membrane. The cavity of the uterus is two-and-one-half inches deep, and this organ, as well as the ovaries and tubules, are healthy.

The large intestine contains a few small, fæcal masses. The liver is found lying in the back part of the abdomen. No blood flows from the cut vessels. On removal, it is seen to be about half the usual size, and very flabby. It is of a uniform, dark-red color. The cut surface is of a lighter red, and after a few moments' exposure, it has a glazed appearance. None of its structure can be made out with the unaided eye. It looks very soft, but it is fairly firm to the touch. Microscopical examination shows the liver-cells destroyed, and replaced by minute, shining granules and molecular detritus.

The gall-bladder contains an ounce of dark, thick bile. The stomach is distended with gas, and contains about three ounces of fluid, in which are some solid pieces of food. Its tissues are of a grayish hue. The duodenum and small intestine contain a quantity of light, slate-colored matter. The portal vein and tissues about it are normal. The pancreas is of a uniform, grayish-white color, of the usual size and appearance. The dura is of normal thickness, and clear and glistening on its inner surface. The pia is transparent. Its vessels, as well as those of the surface of the brain, are moderately full of blood. On removing the brain, there is a quantity of bloody fluid left in the basis crani. Vessels at the base of the brain moderately full of blood, and there is a soft, grayish clot in the basilar artery. This is not adherent, and is easily removed. Section of the brain and great ganglia shows nothing abnormal.

This case is interesting for the reason that it is a typical one, both in its history and pathological appearances as revealed at the autopsy, of a fatal disease and also a very rare one, as only about two hundred cases of acute yellow atrophy have been observed, as the red atrophy it supposed to be a later stage of the yellow, of course a very much less number of this form of the malady have been studied. The cause of this fatal disease is not well determined. Most of the authors the reader has consulted, give mental emotion and the shock that comes as a result of such a disturbance, as one of the causes, while others are inclined to the belief that it should be classed as an acute infectious disease; in support of this theory Klebs claims that he has found micrococci in the hepatic veins; this view is also sustained by the pathological changes that take place in other organs, changes such as are found in most acute infectious diseases. This question of cause became a very pertinent one in the case just related. At the judicial hearing in the case of the husband the following question was asked the medical examiner: If great mental emotion is one of the usual causes of this disease, may not the shock sustained by this woman, resulting from fear and the severe exposure to cold and wet immediately after the assault have been its cause in this case? The opinion given was: That this was not the cause of the disease, and the reasons for this opinion were, that the mental emotion referred to by authors as the cause of this malady, if in fact it is ever the cause of it, were the severe forms of grief or fear that produce well-marked effects, such as coldness of the surface, feeble pulse, etc., and this woman at no time showed any such symptoms of shock. There was some question by the physician who saw the autopsy, as to whether the hæmorrhages about the trachea and beneath the pleura, were not the result of mechanical violence. I am convinced from their extensive distribution as well as their general appearance they were not, but were the result of the disease of the liver. This left the cause, as I have said, a vital one, for if the fatal illness was the result of the brutal treatment of the husband, then he must stand accused of murder; if not, that was the end of the case legally. The pathology of acute atrophy of

the liver, all authors agree, is a rapid fatty degeneration of the liver cells, but whether the so-called red atrophy is a later stage of the yellow atrophy can I think be fairly questioned, and for these reasons: The cases of red atrophy are, I believe, the most acute, and run the most rapid course. In this case Dr. Bryant saw the patient the afternoon of November 19th, and she died the night of the 21st. In the cases of yellow atrophy when the liver has been reduced to one-half or even one-third of its normal size it still preserves its yellow color or at most only presents red patches. It would seem the more probable that the pathological changes in both the red and yellow atrophy are the same, but in the former the disease is the more active and severe, overwhelming the organ at once and destroying its function, while in the yellow atrophy the secretion of bile is not wholly stopped at once, but goes on for a time, and as it is imprisoned in the smaller passages by the swelling, it is reabsorbed and thus the organ is stained. The marvellous shrinking that takes place in the later stage of the disease is undoubtedly due in part to the absorption of the fatty matter, and in part to the absorption of water in the parts of the organ where the circulation has ceased.

INJURIES OF AND OPERATIONS UPON THE KIDNEY.[1]

BY EDWARD O. OTIS, M.D.

THE majority of the nephrectomies have been done through the loin, the extra-peritoneal operation. It is generally the ovariotomists and gynæcologists who favor the abdominal method. For instance, Knowsley Thornton maintains that the abdominal incision does not add much to the risk of the patient, if the surgeon will make his abdominal exploration thoroughly aseptic. Mr. Lawson Tait [28] says he does not think it matters much whether the organ be attacked by what is called the abdominal method, or the lumbar. The general surgeon, however, favors the extra-peritoneal operation, and thus far, the statistics show a much less mortality. The advantages of the abdominal operation are a larger field of operation, with all that means, which is, of course, of immense importance, and an examination of the diseased organ and its relations, as well as the other kidney, if possible, if the conditions of the case render this important.

I will briefly sketch the technique of the lumbar operation: The latero-abdominal position is to be chosen, and a cushion or pillow placed under the flank, so as to make prominent the field of operation. Simon's original incision (Fig. 1, A B), largely in use now, was made along the outer edge of the quadratus lumborum muscle, two-and-a-half to three inches from the spinous processes of the lumbar vertebræ, extending from the superior border of the eleventh rib to the middle of the space between the twelfth rib and the iliac crest. Many surgeons [29] have modified this: Bruns, Czerny, Clement Lucas, Morris, Kleinenberger, Polaillon, and others. Vertical, oblique, and curved incisions have all been made. Weir says a vertical incision (Fig. 1, C D) from just below the twelfth rib to the crest of the ilium, about three inches from the spine, affords ample room for a nephrectomy of a normal kidney. The incision which would seem to be the most satisfactory, as affording the most room, is the inverted L one thus, Γ (Fig. 2, E F), which is made as follows:

First, an oblique incision, like that for colotomy, within about one-half an inch of the last rib, and parallel to it, is made, about four-and-a-half inches long. A second incision runs vertically down from the first, beginning at or near its posterior extremity, along the outer edge of the quadratus lumborum muscle, and extending to the iliac crest. Mr. Morris advises leaving the second incision until the kidney has been exposed, and then it can be made by cutting from within outwards with a probe-pointed bistoury, steadied by the index finger of the left hand. Polaillon's incision, which is recommended, is the reversed L one, thus ⌋, the vertical incision being the outer one, and the transverse branch directed forwards, parallel to the iliac crest. The next step in the operation is laying bare the kidney, and the third, separating the organ from its surroundings. The last, which Simon says is the hardest and longest, is tying the pedicle and cutting loose the kidney, which Mr. Lucas also says is the chief difficulty in the operation. Whether the pedicle is to be tied *en masse* or by separate ligatures, must depend upon circumstances and the creed of the surgeon.

The operation accomplished, the cavity is to be washed out with an antiseptic fluid, a chloride-of-zinc solution, for instance, one or two drainage-tubes inserted, the wound closed, and an antiseptic dressing applied. The accidents of the operation are injury of the peritoneum, hæmorrhage, cut or tear of the colon, and wounding of the pleura. In suppurative affections, also, there is great danger from adherence to neighboring organs, as terribly illustrated in a case of Billroth's quoted by Guyon,[30] where the inferior vena cava and right renal vein were ruptured, even with the more ample room of an abdominal incision.

Peritonitis and septic peritonitis, Guterbock [31] says, are unknown as sequelæ to lumbar nephrectomy, but pyæmia and septicæmia are more frequent than after abdominal nephrectomy.

Nephrotomy (lumbar) is substantially an incision into an abscess sac or cyst, often a preliminary operation to nephrectomy. If there is a tumor in the loin, this will be the guide for the incision, which is similar to that for lumbar colotomy, only a little posterior to it. It is slightly oblique in the ilio-costal interspace, beginning over the outer border of the erector spinæ, and continued forward for three or four inches. The operation is an extremely easy one, says Mr. Tait. The table of statistics shows that it is a less dangerous operation for suppurative lesions than nephrectomy; and, being first done in this class of cases, robs a subsequent nephrectomy of much of its danger.

Marchetti's [32] celebrated case, fairly well substantiated, which happened way back in the seventeenth century, about 1683, might, I suppose, be called in modern nomenclature, a case of nephro-lithotomy. Besides the interest which the case itself excites, it is so attractive in its quaint style, as related

by Charles Bernard, and incidentally in the glimpses of character of both surgeon and patient, that I will give an abstract or two. It was the case of a Mr. Hobson:

"This gentleman, who was consul for the English at Venice, having been afflicted with a stone in the kidney" (how he arrived at his diagnosis the account does not state), "was at length attacked with a fit of that duration and violence, that it reduced him almost to desperation; and, finding no relief from any means that had been used, he determined to apply himself to Dominicus de Marchetti, at Padua, a famed and experienced practitioner there, the son of Peter, both well known to the learned part of their profession. To this person, Mr. Hobson, under the greatest extremity of pain imaginable, addressed himself, imploring of him that, having made use of all conceivable means, and the best advice that was to be had in Venice, without success, he would be pleased to cut the stone out of his kidney, in his belief that no other method remained capable of relieving him, adding that he was not insensible of the danger, but that death itself was infinitely more eligible than a life in that misery under which he had long, and did then groan. Marchetti seemed very desirous to have declined it, representing not only the extreme hazard, but, as he feared, the impracticableness of the operation, that 'twas what he had never attempted, and that to proceed to it was, in fact, to destroy him. But, Mr. Hobson persisting that, if he refused it, he would never desist 'til he found out one who would do it. Marchetti was at length, by his resolution and importunity, prevailed upon to undertake it; and, having prepared himself as he thought convenient, he began with his knife, cutting gradually upon the region of the kidney affected so long, till the blood disturbed and blinded his work so, that he could not finish it at that attempt, wherefore, dressing up the wound till the next day, he then repeated and accomplished it by cutting into the body of the kidney, and taking thence two or three small stones, he dressed it up again. From this instant, he was freed from the severity of his pain, and, in a reasonable time, was able to walk about his chamber, having been in no danger either from flux of blood or fever. Marchetti continued to dress the wound for a considerable time, but was not able to close it up, it soon becoming fistulous from the continual flowing of the urine through the sinus; but, being in all other respects restored to health and vigor, and the matter discharged being little, he took leave of the Professor, and returned to Venice under the care and management of his wife, who, one morning, as she was dressing the sore, fancied she felt something hard and rugged as she wiped it, upon which, examining a little more carefully with her bodkin, which served her instead of a probe, she found it to be a stone of the figure and magnitude of a date-stone, which, being removed, he never after complained of the least uneasiness in the part."

When, through the irritation of the calculus, an abscess is formed, and a tumor appears, and we have calculous pyelitis, "then, indeed," said this same Charles Bernard, "the necessity and reason of the operation are so obvious, and the difficulty so little, that no man ought to decline it." But an operation before the calculus [33] "has occasioned destructive changes, which are liable to terminate in the death of the patient, whether he be abandoned to nature's efforts, or be afforded a chance by a resort to the knife." That is to say, an operation, as a preventative measure, is the thing to be desired. But here comes in, alas! the difficulty in diagnosis, which, in the majority of cases, is conjectural only.

The signs of renal calculus which warrant a lumbar exploration of the kidney, says Mr. Chavasse,[34] are: (*a*) blood in the urine; (*b*) unilateral pain passing down the ureter towards the testes; (*c*) pain elicited by deep-seated pressure in the lumbar region, between the last rib and the iliac crest, just external to the erector spinæ muscle; (*d*) the presence of uric-acid and oxalate-of-lime crystals in the urine. Moreover, he adds, the surgeon is justified in an exploration in those cases of chronic nephralgia depending on uncertain causes, which milder means and medicine have failed to remedy; and, even if no stone is detected, instances have been recorded in which prolonged relief has been obtained.

Paroxysmal lumbar nephralgia and hæmaturia, both aggravated by exercise, pain shooting from loin to groin, and testes, with retraction of the testes, is a classical group of symptoms of great reliability, says another.[35] In still another case operated upon, the symptoms were occasional acidity of the urine, appearance and disappearance of pus, pain in the region of the left kidney, and hæmaturia.

Mr. Owen [36] operated and found a calculus in a case where the symptoms were pain in region of the spermatic cord, running down the thigh, with urine often thick and bloody.

In Mr. Morris's first case, the symptoms were attacks of renal colic and hæmaturia.

Dr. Gross [37] says the best diagnostic symptoms of renal calculus are intermittent attacks of renal colic, with tenderness on pressure; the presence of blood; and, perhaps, a little pus in the urine, with frequency of micturition. "This group of symptoms being present," he says, "the surgeon is certainly warranted, after the failure of ordinary remedies to relieve them, in cutting down upon the kidney, through the loin, with a view to its exploration with the finger, a needle, and, if needed, by an incision of the kidney-substance itself, through which the finger can be carried into the calices and pelvis of the organ."

The position of the calculus in the kidney, whether in the pelvis or substance, has been thought [38] to make a difference in the symptoms, which would seem natural. If the calculus were in the pelvis of the kidney, there would probably be pus in the urine, and the symptoms would be more severe and more constant than if the stone were in the substance of the organ. As the dangers from nephro-lithotomy are not great — in sixty-three examples of attempted and accomplished nephro-lithotomy, there were only three deaths, or 4.76 per cent. [39] — it would seem to be sound surgery to cut down upon, and explore the kidney, whenever the symptoms are such as to give reasonable expectation of finding the calculus. Suppose the surgeon does find himself deceived in his diagnosis, he has caused his patient no great risk, for, in twenty-

nine cases collected by Dr. Gross,[40] in which the kidney was cut down upon, and in four of which it was cut into, and no stone found, all recovered.

That surgeons are more and more following the lead of Mr. Morris every day, is manifest from the increasing number of recorded cases; and, in the future, it is to be hoped that they will be eager to relieve their patients, through operative interference, from the intolerable agony of renal colic from calculus, and not wait to be implored by them in desperation, as Mr. Hobson did Marchetti. "The wise surgeon," says Mr. Morris, "will not wait too long, watching the *vis medicatrix naturæ* — a force which, with renal calculus disorders, as with so many others, too often ends by handing over the patient to the sombre solicitude of the undertaker."

The incision for nephro-lithotomy (Fig. 2, II I) has generally been made parallel to the last rib, from one-half to an inch-and-a-half below it, beginning at the edge of the erector spinæ muscle, and extending four to four-and-a-half inches. This incision may be supplemented by a vertical one, as in nephrectomy, if more room is desired, or the simple vertical incision alone may be sufficient. When all hæmorrhage is stayed, the edges of the wound being held widely apart with retractors, the perinenal fat is to be torn through; and, when the kidney is reached, the finger carefully explores the posterior surface of the organ, the abdominal walls of the patient, meantime, being well supported by an assistant, or pillow. If nothing indicates the presence of a stone on the posterior aspect, the anterior surface is to be explored next, the kidney being pressed backwards by the finger which is exploring the front surface. If the result is negative, a fine needle is to be passed into the renal substance in va-

Hæmaturia was present in seventeen cases, absent in five, and in five it is not known whether or not it was present.

rious directions, so as to puncture the calices of the kidney.

Finally, an incision may be made into the calices, and the interior of the kidney explored with finger or probe. The stone, being found, is best removed by the finger, if possible; if not, by forceps. The operation completed, a drainage-tube is to be inserted, the wound closed, and an antiseptic pad or dressing applied. The dangers — not great — of the operation to be kept in mind are hæmorrhage, cellulitis, renal abscess, and fistula. Healing is generally rapid.

In conclusion, I desire to express my sincere thanks to Dr. Chadwick for the loan of much valuable literature upon the subject.

MORTALITY STATISTICS OF NEPHRECTOMY AND NEPHRO-LITHOTOMY.

NEPHRECTOMY.

Lumbar Incision.

By whom collected	No. of Cases	Deaths	Per cent.
Gross	111	41	36.93
Brodeur	125	47	37.60
Harris	50	19	38.00
Czerny	36	13	36.11
Marduel	24	7	29.16
Otis	18	2	11.11
Average per cent., 31.48.			

Abdominal Incision.

Authors	No. of cases	Deaths	Per cent.
Gross	120	61	50.83
Brodeur	110	55	50 00
Harris	46	23	50.00
Czerny	28	16	61.54
Marduel	28	18	64.28
Otis	8	4	50.00
Average per cent., 54.44.			

NEPHRO-LITHOTOMY.

Authors	No. of cases	Deaths	Per cent.
Gross	21	2	9.52
Brodeur	36	8	22.22
Otis	21	2	9.52
Average per cent., 13.75.			

NOTE.— The same cases are probably included in many of the lists, but this does not make so much difference where only an estimate of the mortality in each operation is desired and the average of all the per cent. is taken.

REPORT ON PROGRESS IN SURGERY.

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

OSTEOPLASTIC RESECTION OF THE MANUBRIUM STERNI.

In a very interesting article by Bardenhauer[1] are presented the indications for the above operation: which are caries of the sternum and to render accessible the contents of the mediastina, for example, trachea, pleura, lungs, tumors, large vessels and other retro-sternal strictures. Lack of space forbids an exhaustive review of this valuable article, but the principal points may be thus briefly reviewed. For the ligation of the innominate artery Bardenhauer recommends a preliminary resection of the manubrium with a transverse resection of the sternal ends of the clavicles and upper ribs. This operation certainly renders the parts more accessible, but cannot always be necessary, for success has followed the ligation of this vessel by Helfrich with the head in the Roser position. Bardenhauer has performed this operation three times in order to render more easy the removal of tumors projecting into the thoracic cavity; with two fatal results from collapse.

For ligation of the sub-clavian in its first operation, Bardenhauer recommends as a preliminary operation, resection of the sterno-clavicular articulation, the first rib, and half the manubrium. He regards any unintentional injury of important strictures due to lack of operative technique. Bardenhauer has performed resection of the sternum four times to expose retro-sternal abscesses, exclusive of eight cases of abscess dependent upon caries of the sternum. For removal of a carious sternum Bardenhauer now performs a very thorough operation, and has thus far had better results than by trephining. The after-treatment consists of a thymol gauze packing. As end results there have been observed the approximation of the clavicles and ribs to the median line, a moderate anterior projection of the shoulders, and a slight degree of kyphosis, (in unilateral resections scoliosis), the interspace is filled with bony tissue from the preserved periosteum. The term "osteoplastic resection" is reserved for cases where the sternum is practically made a temporary door which is hinged at one border by uninjured soft tissues. This "door" can be opened, the cavity of the mediastina inspected, and the "door" again closed and fastened by sutures in

[1] Osteoplastiche Resection des Manubrium Sterni, Mittheilungen aus dem Kölner Bürger-hospital, 1 Heft, 1886.

its original position. This operation has never been performed.

The wounding of the plura is claimed to be free from danger if it at once be closed by an antiseptic tampon.

AORTIC ANEURISMS TREATED BY GALVANO-PUNCTURE.

Olelar[2] has treated a case of aneurism in the first part of the aorta. Great pain existed, soon a tumor was noticed over the second left costal cartilage, and dysphagia appeared.

A Spamer battery of twenty cells was used. The needles were inserted about one inch apart. The current was gradually increased from two to ten cells, and then gradually lowered to two cells again. The séance lasted ten minutes. The patient complained of burning pains in the sac and in the left chest for some hours after each operation.

The tumor became harder and pulsated less; the dysphagia was relieved and the general condition improved; the pains however continued. The tumor after the lapse of a month began to enlarge and pulsate.

Brancaccio[3] recorded a case of aneurism of the ascending aorta cured by electrolysis. The patient recovered and died three years later — of double pneumonia. The post-mortem appearance of the cured aneurism are recorded.

THE RESULTS OF PYLORECTOMY AND GASTRO-ENTEROSTOMY.

A recent résumé[4] gives some valuable information concerning the former operation, first introduced by Peau and Billroth, in 1879. The opinions as to its real value and beneficial results have varied, much as the number of reported cases have increased. Sufficient clinical data, however, have now been collected to enable one to form a just opinion of this remarkable operation.

The indications for the operation are carcinoma of the pylorus, cicatricial stenosis and gastric hæmorrhage, or perforation.

A majority of the cases of pylorectomy have been cases of cancer, mortality seventy-five per cent. The mortality in cases of cicatricial stenosis either from ulcer or ingestion of caustic liquids is about fifty per cent. Richter's table (August, 1886), gives a mortality of seventy-two per cent. for one hundred and three cases of all kinds, while Billroth's death-rate (1880 to 1886), shows only fifty-five per cent.[5]

There is also a great difference in the final results in operations for cicatricial stenosis and cancer, as well as in the mortality of these two sets of cases. In cancer of the pylorus there is no case on record in which a radical cure has been effected, death occurring from recurrence, either in situ or metastatic, in from four months to five years.

Of fifteen cases which survived the operation

2 lived	4	months.

1 "	3	"
1 "	5	"

1 alive at end of 2 years. End not known.

In four or five cases patients were restored to a state of tolerable usefulness, the gastric distress relieved and normal digestion obtained for more than two years, and about an equal number for twelve to fifteen months. To offset this relief enjoyed by a fortunate few, is the high death-rate attending the operation. That the condition of the patient warrants the risk involved by such an operation depends much on the individual case. The chances are strongly against a successful result.

Resection for non-malignant stenosis has a much more favorable record. Here, a successful operation means a permanent cure. Rydygier's results show two cases alive and well at three and six years after the operation. A case of Billroth's is reported in perfect health at the end of three years. Rydygier goes so far as to advise pylorectomy for pyloric ulcerations. Excision for ulcers not pyloric, is also possible. But notwithstanding this, the favorable results and lower death-rate of Loreta's digital divulsion in cases of cicatricial stenosis deserves earnest consideration before a patient is subjected to the more dangerous operation. In regard to recurrence, results vary. Kocher has seen marked symptoms of recurrent stenosis in two cases, one of which survived the operation six months, the other three years, while Wölfler's patient survived extirpation of the pylorus five years, without stenosis.

The value of pylorectomy may be stated as follows: The death-rate in cases of carcinoma is seventy-five per cent. and of the surviving twenty-five per cent. death from recurrence occurs in sixty per cent. In view of this result, the operation of gastro-enterostomy demands consideration as a palliative operation, which, if it does not cure, has satisfactorily relieved, a result which equals that obtained in many cases by pylorectomy. Cicatricial stenosis with fifty per cent. permanent recoveries are apparently the cases in which this operation appears in its most favorable light.

The most thorough review of the subject of gastro-enterostomy is that of Rockwitz,[6] of Strassburg. His conclusions are based on a careful investigation of twenty-one cases. Fisher's[7] case, already fully reported, and also Billroth's,[8] where gastroenterostomy was combined with pylorus, resection being excluded.

This table shows seventeen cases of stenosis due to cancer, and four of cicatricial stenosis pyloric duodenal. Total number of recoveries nine, six of which were carcinomatous. Total mortality 57.2%, of cancer 64.7%. Eleven died directly from the operation as follows: eight from collapse or exhaustion in less than three days after the operation. One from internal hæmorrhage from the wound; one from peritonitis on the fourth day; one from exhaustion (on the tenth day) due to vomiting caused by a spur which obstructed the afferent portion of the attached loop. One also died from marasmus at the end of four weeks. The remainder survived free from trouble. The above is the results from the full table, but at Strassburg, Lücke has operated eight times, two for stricture and six for cancer, with one death, while the record from Billroth's Klinik shows eight cases, with five deaths directly due to the operation. The rate, therefore, of mortality in these two hospitals is very different. Rockwitz's article is too elaborate to be more than

allu led to here, but a careful perusal is recommended to those interested in this subject, or at least, the interesting review recently published.[9] In brief, the difference in results obtained at Strassburg and Vienna, is apparently due to the class of cases and method of operating. The Vienna[10] cases were, seven patients with unoperable pyloric carcinoma and one with a tuberculous stricture. Three recovered from the operation and were living at the end of one, two and four months afterwards. The high mortality is attributed to the debilitated condition of the patients at time of operation, and that the operation was often done only after fruitless attempts to excise the pylorus, which prolonged greatly the operation and necessitated additional exposure and manipulation of sensitive tissues.

On the other hand, Lücke's cases all recovered save one, and lived at least several months in comparative comfort, fourteen months in one case. Both cases of non-malignant stricture were permanently relieved; a mortality of 12.6% against Billroth's 63.6%. The post-mortem condition of Lücke's cases was, as a rule, satisfactory, with one exception, in which a cicatricial contraction occluded the efferent loop of intestine.

Rockwitz's conclusions state that gastro-enterostomy is indicated in cases of pylorus or duodenal stenosis if resection is impossible. Also, all cases of carcinoma with extensive adhesions or glandular metastasis. Conversely that pylorectomy is contra-indicated if adhesions exist between the tumor and the pancreas or liver, where glands are extensively involved or the patient is in an exceedingly weak state.

The following points are of importance with reference to the operation:

(1) All preliminary breaking down of adhesions, isolation of the tumor or unnecessary manipulation of the abdomen, are especially to be avoided. They increase the danger of infection and weaken the patient.

(2) The linea alba is the best site for the abdominal incision.

(3) It is not necessary to find the first coil of jejunum as taught by Wölfler. It is more advantageous to select a coil of intestine which is easily accessible. The afferent end may be recognized by arousing its peristaltic action (vide Nothnagle test). This simplifies the operation, and diminishes the danger of compressing the colon with the reflected mesentery.

(4) The direction of peristaltic action of the stomach and intestine should correspond; that is, its direction should be from left to right.

(5) The kind of suture is not so important as its accurate application.

(6) When disturbance of peristaltic action occurs, the stomach pump or tube is of value.

DRAINAGE OF PELVIC ABSCESSES.

Rinne,[11] at the Fifteenth Surgical Congress in April, 1886, reported two cases of pelvic abscess of very long duration, which had rapidly recovered after trephining the ileum, and thus establishing a direct system of drainage. The bone was exposed by an antero-posterior incision at a point three fingers breadth above the trocanter. The ileum was then chiselled through, giving an opportunity for the exploration of the abscess cavity with the finger, and thoroughly draining it after curetting. This method is not dangerous, and is valuable for the treatment of abscesses situated in the iliac fossa, which have resisted obstinately the ordinary treatment.

THE "KONIG" INCISION FOR OPERATIONS ON THE KIDNEY.

König, after an investigation by dissections and operations on the living subject for the purpose of ascertaining the most advantageous method of exposing the kidney, has decided in favor of the following operation.[12] The primary incision is started at the twelfth rib, at the external border of the erector spinæ muscle, and continued downwards along the border of this muscle to within a few centimetres above the iliac crest. From this point it is curved forwards towards the umbilicus, terminating at the external edge of the rectus muscle. If necessary, it can be continued even to the navel. It is often advantageous to give the first part of the incision an oblique rather than a perpendicular direction, so that it forms with the transverse portion a moderate curve (Czerny). The tissues are divided to the peritoneum, the cut edges of the individual muscles being marked by knotted sutures, so that they can afterwards be identified and united.

This incision, König claims, makes the kidney surprisingly accessible, especially if the peritoneum is separated with the hand from behind and pushed forward. He proposes to call this method the "retro-peritoneal lumbo-abdominal incision." If, on account of insufficient space for diagnostic or operative purposes, it is necessary to obtain access to the tumor through the abdominal cavity, this can be readily accomplished by incising the peritoneum in the line of the transverse incision. It should, however, be reunited by suture before any infective material is evacuated from the kidney; as, for example, the removal of a suppurating kidney or an incision in case of a putrid pyelo-nephritis. The author closes with a report of two cases, one a large renal calculus, the other suffering from pyelitis, operated on in this way, with satisfactory results, and emphasizes the importance of preventing abdominal hernia, by dividing muscles in the direction of their fibres and accurately suturing their edges. The sutures should remain for three weeks after the operation and the patient should remain quiet in bed for at least four weeks.

SUPRA-PUBIC LITHOTOMY.

Thomas Annandale[13] summarizes the new method of performing supra-pubic lithotomy as follows, and considers that it is not only applicable to children, but also to adults:

(1) The gradual and thorough dilatation of the bladder by the injection of some antiseptic fluid.

(2) The introduction of a lithotrite, and the seizing and fixing of the stone in its blades.

(3) The depression of the handle of the lithotrite, so as to press the stone against the abdominal wall, immediately above the pubes, in the median line.

(4) Cutting down through the abdominal wall, in the middle line, upon the pubes, and immediately above it, in the usual way, until the bladder is reached.

(5) Depressing the handle of the lithotrite still more

[9] Med. News. Vol. li., 187, 191.
[10] Deutsche Zeitschr. f. Chir. Rockwitz. Bd. xxv, S. 307.
[11] Centralbl. f. Chir., 1886. No. 24, Beilage.
[12] Centralbl. f. Chir., 1886, No. 35.
[13] British Medical Journal, October 9, 1886.

so as to stretch the wall of the bladder over the stone, and make it prominent at the wound.

(6) Incising the stretched bladder-wall upon the stone to a sufficient extent, in a downward direction, and then protruding through the opening the stone and the blades of the lithotrite.

(7) Gently opening the blades of the lithotrite and removing the stone, and, in withdrawing the lithotrite, catching one end of an India-rubber catheter in its blades, and bringing it out through the urethral orifice, the other end of the catheter being left in the bladder.

(8) Stitching the wound in the abdominal wall, and introducing a drainage-tube at its lower end. If the wound in the bladder be small, Annandale considers it better not to stitch it, if large catgut sutures may be inserted. The dilatation of the rectum he regards as only a complication to the operation.

FRACTURE OF THE ULNAR IN THE UPPER THIRD, WITH DISLOCATION OF THE RADIAL HEAD.

The rarity of this injury, its limited literature, and great practical importance, has led Dr. Hans Doerfler (Nüremberg) [14] to make it the subject of an especial investigation. After reporting four cases which had come under his personal observation, he analyzes a group of nineteen cases, which he succeeded in collecting. It was caused by direct violence in five, and by combined, for example, as from a fall, in eleven. A majority of cases were between the ages of three and fifteen. All others after thirty-five. From experiments on ten cadavera, he concludes that both injuries can occur simultaneously, but that the fracture is primary, and the dislocation secondary, and cannot occur if the ulnar is fractured below the upper third. After describing the symptoms of this injury, the writer proceeds to the discussion of the prognosis and treatment. When treatment is begun at once, or even within the first six weeks, the prognosis is good. After two months, capsular degeneration diminishes the hope of a successful termination; but, as a new capsule soon forms at the point where the radius rests, its function may be to an extent restored if the ulnar unites. Arthritis deformans may be a late result.

The prognosis of paralyses is unfavorable. As regards treatment, it is of great importance to consider the possibility of radial dislocation in all fractures of the ulnar. If present, this should be reduced by extension and direct pressure from below. The elbow is then flexed at an acute angle (to relax the biceps), the forearm semi-pronated, and a stiff bandage applied, which should be undisturbed for from four to six weeks. Semi-supination is to prevent the new-forming callus from reproducing a displacement. In old cases, resection of the capitulum radii is indicated if reduction fails. Osteo-palinclasis of the ulnar may be, at times, necessary.

ANTISEPTIC IRRIGATION OF THE KNEE-JOINT.

A very interesting article has been published by Dr. Robert F. Weir,[15] in which this method was strongly recommended. The treatment is considered indicated in (1) subacute or chronic synovitis, where the usual treatment has failed after a fair trial; (2) hydrops articuli, at once; (3) threatened pyo-arthrosis, at once; (4) obstinate cases of gouty synovitis.

It can be also used in cases of acute synovitis with painful distension, hæmathrosis, and pyo-arthrosis. The details of the procedure are carefully described. The fluid for irrigation is usually a three to five per cent. carbolic solution, but, in cases of threatened purulent synovitis, a one-tenth per cent. sublimate solution is substituted.[16] In ordinary cases, the reaction is moderate, lasting twenty-four hours. The dressing is changed after seven to ten days, the patients recovering promptly, with few exceptions, and invariably without toxic symptoms. In cases of "Hydrops Articuli" with excessive relaxation of ligaments, three to four injections, at intervals of several weeks, has caused sufficient shrinkage and thickening of the capsule and ligaments to steady the limb (Volkmann).

MALGAIGNE'S HOOKS IN THE TREATMENT OF FRACTURE OF THE PATELLA.

Mr. Frederic Treves [17] considers that the use of Malgaigne's hooks is the most satisfactory treatment of fractures of the patella. The failure of the hooks depended upon the danger in their use; but, to-day, Mr. Treves tells us that he has used them under antiseptic precautions, for the past twelve months, in all his cases, and has never had reason to regret their use. He applies them in the following manner: No anæsthetic is required; the limb is securely fixed on a back-splint, which keeps the knee fully extended, a foot-piece preventing any shifting. The surface of the knee is antiseptisized. The borders of the patella are mapped out by pencil, and the points for the introduction of the hooks indicated. The hooks should enter the bone at equal distances from the median line. Four punctures are now made with a sharp tenotome at the points where the hooks are to enter. The two upper punctures open the synovial cavity, and through them the fluid in the joint is easily evacuated. The two lower punctures are external to the joint. When all fluid has escaped, the hooks are applied. They should be aseptic. The two parts of the apparatus must be separated, and each portion applied by itself, it being better to apply the lower hooks first, since there is often difficulty in applying the upper ones. Finally, after the hooks have secured a good hold on the bone, they are screwed together, so that the fragments are brought into close contact. The upper fragment tends to "ride." The four punctures are then covered with iodoform, and the limb is placed on an inclined plane.

This completes the dressing, the hooks being always in sight. In the cases so far treated, there has been neither rise in temperature, pain, suppuration about the punctures, nor trouble in the joint. The hooks are removed at the end of six weeks.

J. D. Rushman [18] has recently read a paper on the treatment of fractured patella at the New York Surgical Society, which deals with the subject comprehensively. He concludes that the best treatment is by Malgaigne's hooks.

A NEW METHOD OF PERFORMING EXCISION OF THE KNEE-JOINT.

Herbert Allingham [19] brings forward an operation for excision of the knee-joint, which, he believes, is new, and which is said to have the following advantages:

[14] Deut. Zeitsch. f. Chir., Bd. 23, Hf. 3 and 4, 1886.
[15] New York Medical Journal, XLVII, No. 8, February 20, 1886.
[16] Schede. Klin. Vorträge, No. 251, 1885.
[17] Brit. Med. Jour., July 24, 1886, p. 153.
[18] Medical News, February 5, 1887.
[19] British Medical Journal, January 15, 1887, p. 106.

The attachments of the fascia lata, the lateral ligaments, and the prolongation of the vasti to the tibia and fibula are not divided.

Above the patella, the synovial pouch is well opened, and the synovial membrane can be thoroughly removed.

The joint and the ends of the bone can be thoroughly examined.

The undivided quadriceps is a strong antagonist to the ham-string muscles, and dislocation of the tibia backward, or tilting of the femur, which commonly occurs after the operation, is thus prevented.

Progression is greatly improved, the attachment of the quadriceps being neither divided, nor the muscle shortened. This is, of course, of great importance, if one hopes for a movable joint.

The operative procedure is as follows: A vertical incision is made from two to three inches above the patella, and prolonged over the patella down to the tubercle of the tibia. All the soft tissues are thus split down to the bone; the patella is vertically sawn in two. These lateral flaps have half the quadriceps' tendon, half the patella, and half the ligamentum patellæ, and are retracted to each side.

The crucial ligaments are divided; then, the leg being flexed, the condyles of the femur are pushed forward on the head of the tibia, and a slice of bone is removed. Now the leg is completely flexed, and the internal lateral ligament is carefully separated from the internal semi-lunar cartilage. This is very important, as this attachment prevents the head of the tibia from coming forwards. The tibia is then pushed forwards on to the femur, and, in order to avoid dividing the lateral ligaments, a thin slice is removed with a strong knife or chisel. The joint is then cleared of synovial membrane, and drainage is made at the posterior-lateral aspects of the cavity.

The patella is shelled out if it is diseased; or, if not, is united by wire. The joint is then closed, all the parts being sutured independently, and an antiseptic dressing applied.

(To be continued.)

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

E. O. OTIS, M.D., SECRETARY, *pro tem.*

MEETING May 2, 1887, DR. C. F. FOLSOM in the chair.

DR. A. F. HOLT read a

CASE OF ACUTE RED ATROPHY OF THE LIVER.[1]

Dr. Holt, in beginning his paper, remarked that, although this case occurred to him while performing his official duties as medical examiner, it was for its medical interest that he reported it, and that he did not refer particularly to its medico-legal aspects.

DR. H. I. BOWDITCH said that this was one of the most interesting cases he had heard in a long time, and asked the reader if, from a microscopic examination of the blood, one could tell when the extravasation took place — whether, for instance, one or three days previous to the examination. He further remarked that he confessed to some misgivings as to the innocence of the husband in the case, and he could not help thinking that he killed his wife, although one ought to be very cautious in judging.

DR. HOLT said that he did not feel entirely satisfied that the attack of the husband had nothing to do with the disease.

DR. DERBY asked what the result of the judicial inquiry was.

DR. HOLT replied that the man was acquitted.

DR. J. J. PUTNAM desired to know some of the other causes of the disease.

DR. HOLT replied that the causes were obscure. Those commonly given were certain mental conditions, such as anger, fear, grief, and the acute infectious diseases.

DR. C. P. PUTNAM asked when the jaundice appeared.

DR. HOLT replied, three days before death.

DR. PUTNAM further desired to know if Dr. Holt had had the patient under careful observation from the time of the maltreatment by her husband until her death.

DR. HOLT replied that she had been carefully watched during this time, and again referred to the exceeding rapidity of the atrophy. In the morning, the liver was apparently normal, and in the evening it had disappeared.

DR. PRINCE asked if there could have been any possibility of phosphorous poisoning.

DR. HOLT said this had been thought of, but there was no evidence to show that such was the case.

DR. MCCOLLOM asked if cases of this disease were often as rapid as this one.

DR. HOLT said that some of them are of exceeding rapidity. Dr. Holt, in conclusion, also said that specimens had been submitted to both Drs. Fitz and Whitney, and they were agreed as to the nature of the disease. Dr. Whitney also reported the finding of blood-crystals.

DR. WADSWORTH read the second paper, upon

A CASE OF RECURRENT PARALYSIS OF THE THIRD NERVE.[2]

In the remarks which followed, DR. DERBY asked if the headaches increased in frequency.

DR. WADSWORTH said they did not, in his cases.

DR. DERBY also asked if there was any especial change during the catamenia.

DR. WADSWORTH said not.

DR. J. J. PUTNAM asked if it was only the third pair that was affected in this way.

DR. WADSWORTH replied that this was the only nerve thus affected so far as he knew, but he would not say positively that others were never affected.

DR. PUTNAM further asked: Supposing the pathological condition is an organic one, what is the cause of the headache and its periodicity? is it congestion about the lesion, or what?

DR. WADSWORTH replied, it was hard to say. It might be periodic attacks of congestion, which caused greater pressure. One author supposed that in a case of tubercular tumor there was a periodical increase in the formation of tubercles which pressed upon the nerve, and caused the paralysis; and, as the patient became habituated to the condition the nerve resumed its function.

[1] See page 374 of the Journal.

[2] Reserved for publication.

DR. PUTNAM referred to an interesting case which came under his observation. It was that of a young girl of fifteen years, who, during the winter, had much headache and other singular symptoms, possibly hysterical. She was unable to hold her water, and her teacher sent her home from school because her eyes looked strangely, and troubled her. Then she had difficulty in using her hands, first the right, and then the left, from ataxia and numbness. She had, also, almost complete paralysis of the third nerve of the right eye. The interesting point in the case was the rapid improvement during the last month, the affection of the third nerve having almost entirely disappeared. She had been taking iodide of potash, but whether or no this had anything to do with the improvement he did not know. This case would not come under the head of any of the recognized affections of the third pair. It might be an anomalous case of the kind reported by Dr. Wadsworth.

DR. WADSWORTH said that, in all the cases reported, there was no paralysis of any other nerve.

DR. PUTNAM thought it curious that no other symptoms appeared.

DR. PRINCE asked how long the intervals were between the attacks of headache.

DR. WADSWORTH said that, with one exception, the longest interval was a year.

DR. DRIVER asked the opinion of Dr. Wadsworth upon a case which happened in his practice. A young girl at the seashore went on a boating party, which got left by the tide, and she was obliged to wade ashore late at night, arriving home much exhausted. Within twenty-four hours, there was confusion of vision, and some paralysis of the muscles of the right eye. Under iodide of potash and nux vomica, these symptoms soon disappeared.

DR. WADSWORTH thought this was one of those cases called rheumatic.

DR. PRINCE exhibited a new

VERTICAL GALVANOMETER,

comparing it with other instruments of the kind. Both horizontal and vertical galvanometers were described. The disadvantage of the horizontal instrument is that it is affected differently at different places by the earth's magnetism, and hence, does not give the same reading in one place as another. The vertical galvanometer, on the other hand, gives the same reading everywhere.

The ordinary galvanometer is, in reality, a galvanoscope, and does not indicate the strength of the current. For the physician, the galvanometer to be desired is one with large readings, which will quickly come to a standstill, not oscillating, and which is absolutely accurate. This last qualification, however, Dr. Prince did not think so important. In the galvanometer exhibited, air was used as a cushion to stop the oscillations.

AMERICAN GYNÆCOLOGICAL SOCIETY.[1]

TWELFTH ANNUAL MEETING.

BATTEY'S OPERATION: ITS MATURED RESULTS,

by DR. ROBERT BATTEY, of Rome, Georgia.

In August, 1872, the author performed his first operation for the removal of the functionally active ovaries for the relief of otherwise incurable troubles. Up to the present time, there have been no statistics as to the ultimate effect of the operation. Reports have been given showing the immediate results, but none showing the results on the affection for which the operation was performed. All the cases reported in this paper had been traced carefully up to the present time. They were all the subjects of a complete Battey's operation, and had all been operated on a year or longer. The name "Battey's operation" was retained, as it expressed the idea of the induction of the change of life artificially for the relief of disease, and this idea is included in none of the other terms, such as spaying, oöphorectomy, etc. Fifty-four cases were reported in the present article. Of these, thirty-three were cured, eight were much improved, five were slightly improved, and eight were not at all improved. In fifty of these cases, a complete menopause was induced, and in four there was a continued pseudo-menstruation. The detailed histories of a number of typical cases were then given. The following conclusions were then presented:

(1) The change of life is the most important factor in securing the complete result of this operation.

(2) In exceptional cases, the cure almost at once follows the operation, but, in the vast majority of cases, the patient must pass through the ups and downs incident to the change of life before the restoration to health is complete.

(3) The length of time required to pass through the nervous and physical perturbation attendant upon the change of life is variable. It may be one year, or it may be three or five years.

(4) Of the cases operated on, a few were no doubt badly selected, and the proper selection of cases is a problem yet to be solved.

(5) Patients who have become addicted to the habitual use of morphia, opium, chloral, or alcohol cannot be restored to health until the pernicious habit is abandoned.

(6) Cases which are the proper subjects of this operation, if allowed to suffer, eventually reach a stage where they become absolutely incurable by any operation.

(7) In a number of cases, the patients were in no wise benefited by the operation. In several of these, the indications seemed clear and unmistakable.

(8) In some cases, neuralgic pain remained. How much this was due to an unabsorbed ligature, was a question to be considered.

(9) A careful analysis of the cases seems to show that the removal of the tubes with the ovaries had no influence in the establishment of the menopause, the only effect of their removal being on the disease of the tubes themselves.

(10) The operation is not an infallible one. The percentage of failures recorded is a notable one, but when it is remembered that the cases included are only those otherwise incurable, each case cured is a positive gain. A like percentage of cures in cases of cancer of the uterus, or of cancer of the breast, would be an achievement of the greatest magnitude.

The discussion of this paper was postponed until after the reading of a paper entitled

THE INFANTILE UTERUS,

by DR. A. W. JOHNSTONE, of Danville, Ky.

The author called attention to the fact that the

[1] Concluded from page 363.

uterus was composed of two distinct portions, the body and the neck, the relation between the two being almost the same as that between the stomach and pylorus. The non-development of the uterus may result from various causes, such as injury, etc. The growth and function of the endometrium was referred to at length. The author had discovered a branch of the sympathetic nerve entering the uterus near the attachment of the Fallopian tube, and he thought it probable that it was through this nerve that the uterus received its physiological orders. He held that it was not the removal of the ovaries and tubes that brought on the change of life, but it is the neurotomy which the removal of these organs necessitates. From this, he argued that the arrest of the growth of the uterus was in all probability due to interference with this nerve-supply. An acute neuritis may often pass unrecognized. One of the most marked symptoms in these cases is pain, resulting from the efforts of the endometrium to perform a function for which it is not capable. In the management of these cases, it seems that, in some of the simpler ones, a certain amount of benefit is derived from the use of stem-pessaries, and from galvanism. In the majority of cases of corporeal deficiency, he considered it undesirable to induce the menopause; but, in some cases, where the ovaries remain large and tender, this operation may be resorted to. In conclusion, the author said, if we wish to have a clear idea of the physiological position of the uterus, we must emancipate it from the thraldom of the ovaries, in whose secure grasp it has been held for the last fifty years.

DISCUSSION.

Dr. R. S. Sutton, of Pittsburg. I would ask if Battey's operation consists in the removal of the ovaries alone, and if in the fifty-four cases reported, the removal of the ovaries alone brought on the menopause in fifty cases?

Dr. Theophilus Parvin, of Philadelphia. Does Dr. Battey find the ovaries invariably diseased, and how often is there associated disease of the tubes?

Dr. Lloyd Roberts, of Manchester, England. I would ask Dr. Battey as to the condition of the uterus in the cases reported.

Dr. William M. Polk, of New York. I would ask what is the condition of the ovaries that demands removal? Can we after the abdomen is opened, tell by the appearance of the ovaries whether they should be left or removed.

Dr. G. G. Bantock, of London, England. I have always understood that Battey's operation consisted in the removal of perfectly normal ovaries. I would ask if this is the correct idea?

Dr. Robert Battey, of Rome, Georgia. In reply to the various questions asked, I would say that I do not restrict the term Battey's operation to the removal of the ovaries. The removal of the ovaries is not a necessary constituent of the operation. Battey's operation consists in the induction of the menopause, no matter in what way it is brought about. The removal of the ovaries does not always bring about the menopause, the removal of the ovaries plus the tubes does not invariably cause the menopause, the removal of the ovaries plus the tubes plus the uterus does not always bring about the menopause. In my experience the ovaries are always diseased, but this is simply an accident of the operation, the operation is not done for the removal of diseased ovaries. Battey's operation is not normal ovariotomy; I entirely repudiate that term. As a rule, I remove only the ovaries, but in a small proportion of cases I remove the tubes, but only when the tube is the seat of positive disease, such as pyo-salpinx or hydro-salpinx. The condition of the uterus varies in each case. I do not insist upon visible changes in the ovary to justify its removal. I rest for my justification on the urgent necessities of the case, and on the fact that nothing else effective has been proposed. I do not operate until all other measures have failed.

A BRIEF NOTE ON THE IMPORTANCE OF THE USE OF ANTISEPTICS IN PRIVATE OBSTETRIC PRACTICE, by Dr. Theophilus Parvin, of Philadelphia.

The question as to the necessity for the use of antiseptics in hospital practice has been settled, but in private practice their use is often omitted chiefly perhaps on account of the trouble and expense involved in their use. The puerperal woman should be as carefully treated in private practice as in the hospital ward. While an obstetrician may attend many cases of confinement without a death from septicæmia, yet he may have had many cases in which the woman has been crippled, as a result of this affection. The day is coming when if a case of puerperal septicæmia occurs in the practice of an obstetrician who does not employ these precautions, he cannot escape the censure of his professional brethren or of his own conscience.

In order to facilitate the use of these agents, the author had prepared a small case containing articles often required in the treatment of a case of confinement. The case contains corrosive sublimate tablets, strong silk for ligating the cord, antiseptic cat-gut, laudanum, ergot, carbolic acid, and tablets of persulphate of iron. There is also a flexible catheter fenaculum, laryngeal tube, needle-holder, scissors, lancet, needle and silk-worm-gut for closing tears of the perineum and within the vagina.

DISCUSSION.

Dr. Lawrence, of Manchester, England. The plan which I pursue is as follows: During the progress of the labor the vagina is several times washed out with a warm solution of carbolic acid, 1 to 200. Within half an hour after the removal of the placenta I insert a suppository of iodoform containing twenty-five grains. This is then used night and morning, and the discharges remain inoffensive. If they should become offensive I know that the trouble is within the uterus, and proceed to wash it out.

Dr. A. R. Simpson, of Edinburgh. The most important thing is that the practitioner should have perfectly clean and odorless hands. I rise to call attention to the value of turpentine in cleaning the hands. Even after the examination of a case of cancer, the use of turpentine will render the hands perfectly clean.

Dr. Reed, of Glasgow. I never examine a woman without using antiseptics. I carry in my pocket papers containing ten grains of the bichloride of mercury, and dissolve one of these in a pint of water and use it for washing my hands. As a lubricant, I use a preparation which was, I think, first suggested in Germany, consisting of three parts of pure soft soap, one part of glycerin, and five per cent. carbolic acid. It is to be kept in collapsible tubes such as painters use.

DR. HOWARD A. KELLY, of Philadelphia. I am in the habit of carrying corrosive sublimate put up in gelatine capsules, each containing seven grains. This will readily dissolve in hot water, or theca psule may be opened and the corrosive sublimate added to the water.

EXTRA-UTERINE PREGNANCY AND ITS TREATMENT BY ELECTRICITY,

by DR. ELY VAN DE WARKER, of Syracuse.

The following case was reported. Mrs. X., aged twenty-seven years, was married at the age of twenty-four. In 1885, she had an abortion at three months. July 25th she had her last menstruation, and August 28th she was taken with severe pain beginning in the pelvis and extending over the abdomen. There was slight collapse which disappeared under the use of morphia. The next day what was taken for menstruation came on. The attacks of pain continued to recur, and on September 17th the decidua was passed. On examination a small tumor was detected to the right side of the uterus and slightly posterior to it. This was about three inches long and one and a-half inches in diameter. Extra-uterine pregnancy was diagnosed. Severe paroxysms of pain continued to recur and on October 6th, the electrical treatment was commenced. This consisted in the use of the faradic current, a strong induction coil being used. The patient was given ten treatments of half-an-hour's duration, one electrode being pressed against the tumor in the vagina and the other applied externally. At the end of this time there was no apparent change in the pelvic mass, and the pain continued. On October 20th, the treatment was continued one hour, and this was repeated on following days until three applications were made. After the first of these applications the tension of the cyst was found to be less. This was regarded as a sign that the fœtus was destroyed, and was believed to be a sign easier of recognition than a diminution in the size of the tumor. The paroxysmal pain also ceased as soon as the tension diminished. In using electricity for this purpose, the applications should be repeated until the subjective and other evidences of pregnancy disappear. In this case the patient recovered completely, but it was seven months before all traces of the tumor had disappeared.

DISCUSSION.

DR. JOHN C. REEVE, of Dayton, Ohio. I have reported one case of extra-uterine pregnancy cured by electricity. Twenty years ago it was pointed out that sudden and violent attacks of pelvic pain attended with gushes of hæmorrhage almost certainly indicated extra-uterine pregnancy. We have since learned that the expulsion of a deciduous membrane is pathognomonic. In the diagnosis of this condition the first thing to do is to determine the probable existence of pregnancy. An important point in diagnosis is that the tumor in the pelvis manifests signs of activity in its circulation, and it grows rapidly. In my case some six or eight applications were made, the current being as strong as the woman could bear. The first sign of its effect was the diminution in the activity of the circulation of the cyst. In my case it was months before all signs of the tumor disappeared.

DR. P. MARION SIMS, of New York. In a case under my care four years ago, treatment by electric shock was resorted to. The patient was anæsthetized and twenty or thirty shocks from fifteen freshly charged cells were passed through the fœtal mass. Eight or ten applications of this kind were given at intervals of two or three days. At the end of this time there was noticed a decided lessening in the tension of the sac. The use of electricity was then stopped. At the end of one year there was still some thickening of the cellular tissue. The patient's health has been perfect since the operation.

DR. JAMES R. CHADWICK, of Boston. One year ago I had a case of extra-uterine pregnancy which I treated with the constant current constantly interrupted. This was continued three or four weeks before the symptoms ceased. Five weeks later the fœtus protruded into the vagina and was removed.

DR. MARTIN, of Berlin. I have operated on sixteen cases of extra-uterine pregnancy. The treatment by electricity has not met with much favor in Germany. Tubal pregnancy is the most common form of this accident, and this can be easily diagnosed and easily operated on. I have operated on nine cases of tubal pregnancy, and all but one have recovered. In this case the tube had burst and the abdomen was filled with blood before the operation was done. Death resulted from the great loss of blood. The treatment of the other forms of extra-uterine pregnancy will depend upon the symptoms and the course. In these cases the chief objection is the danger of hæmorrhage from the placenta, but I have experienced no difficulty in dealing with the placenta.

DR. MATTHEW D. MANN, of Buffalo. The electrical treatment of these cases has advantages over all other methods of treatment. The dangers connected with the use of electricity where puncture is not made are very slight. If this method fails we can still perform laparotomy.

DR. APOSTOLI, of Paris. Where a case of extra-uterine pregnancy has been diagnosed in its earliest stages, the use of electricity should be tried before resorting to any operative procedure. The faradic current is not to be depended on. I have accidentally used the faradic current on the womb in cases of pregnancy, not knowing that the condition was present, and no abortion has resulted. On the other hand, I have accidentally used the galvanic current under these circumstances and abortion has been induced. I would recommend the introduction of one electrode into the sac, while the other is applied externally and in this way if a strong current is used, the death of the fœtus is assured at one sitting.

DR. JANVRIN, of New York. Last year I reported a case of extra-uterine pregnancy, in which galvanism was employed. The patient died from bursting of the tube after the third application. I have become convinced that the condition of collapse and collicky pain observed in cases of tubal pregnancy, is not due to distension of the sac, but to the rupture of small vessels in the peritoneal covering of the tube. The treatment of these cases is not galvanism, but as soon as we have made our diagnosis, we should on the first evidence of shock and collicky pains, at once remove the tube by laparotomy, and thus give the woman a chance of being a well woman.

DR. ELY VAN DE WARKER, of Syracuse. It has been shown that the use of electricity is not dangerous and if it fails we can resort to laparotomy. If Dr. Janvrin's view is right, we should have hæmatocele,

but in my case where there were repeated attacks of pain, there was no evidence of hæmorrhage. With reference to the recommendation of Dr. Apostoli, I think that the introduction of an electrode into the sac would be as dangerous as laparotomy.

AFTERNOON SESSION.

VAGINAL INJECTIONS IN SIMS' POSTURE,

by Dr. Frank P. Foster, of New York.

The value of large vaginal injections of hot water in the treatment of inflammatory conditions of the pelvis is now recognized. Even when the rules ordinarily laid down are faithfully carried out, it is possible that the efficiency of this measure may be still further increased. The main desiderata are the penetration of the water to a position closely contiguous to the seat of disease and its application in a quantity sufficient to secure the maximum action of the heat. To fulfil these requirements the speaker had used the injections with the patient in Sims' posture or rather in a posture somewhat more prone than that of Sims'. With the woman in the dorsal position the quantity of water in the vagina at one time is decidedly smaller than that which is required to fill the canal when it is distended by atmospheric pressure, as occurs on opening the introitus with the patient in Sims' posture. It seems reasonable to suppose that the effect of a large quantity of water in the vagina will be greater than that of a small quantity. When the injection is concluded this large quantity of water can be retained for some time. The greatest advantage is, however, the gravitation of the abdominal contents towards the diaphragm, thus bringing the hot water in closer relation with the diseased parts. With the ordinary appliances there is some objections to this procedure, but with the vaginal douche, described some years ago by the author, no difficulty is experienced.

A NOTE ON THE TREATMENT OF PUERPERAL ECLAMPSIA,

by Dr. Charles Jewitt, of Brooklyn.

The object of the paper was to call attention to the value of veratrum viride in this class of cases. Its use in convulsive affections has been known for many years, but has not been generally recognized. Veratrum viride, if a reliable preparation is employed, is a safe, prompt and efficient remedy in convulsions. Its value in eclampsia seems to depend on its effect on the vaso motor tonus. Used with proper precautions veratrum viride is perfectly safe. A careful search of the literature reveals no death due to its use in the treatment of convulsions. It is important that the patient should be kept in the recumbent position while taking the drug. The fluid extract of the rhizome is the best preparation. Hypodermic injections of the drug is the only reliable way of bringing the circulation promptly under its influence. The average dose is ten to twenty minims. The smaller dose repeated in half an hour will usually suffice. The guide to the use of the drug is the frequency of the pulse. Experience has shown that no convulsion will occur if the system is sufficiently under the influence of the drug to hold the pulse under sixty per minute. The average time required to develop the effect of a single dose of the drug is half an hour. The average quantity given does not exceed twenty or thirty minims in all. Twenty-two cases were reported in which this plan of treatment had been employed. Of this number six died, three by complication, and three from the eclampsia. In the fatal cases from twenty-four to thirty convulsions had occurred before the treatment was begun. In most cases other remedies, such as chloroform and hydragogues were employed in addition to the veratrum viride. The most unpleasant effect noticed has been nausea and depression, but these were only transient.

DISCUSSION.

Dr. King, of Washington. I suggested the use of this remedy on theoretical grounds some twenty years ago. At that time, I endeavored to account for the convulsions of pregnancy by the pressure of the gravid uterus on the aorta and its branches and the consequent excess of arterial blood in the brain. In primiparæ, in whom this condition occurs most frequently, it is usual for the head to descend below the brim of the pelvis some time before full term is reached. In multiparæ it is the exception for the head to so descend. I would suggest that the difference, or the liability to eclampsia between primiparæ and multiparæ is due to this difference in the position of the head.

Dr. Jewitt, of Brooklyn. The correctness or falsity of Dr. King's views could be demonstrated in a case of this kind by performing version by external manipulation, thus removing the head from the brim of the pelvis. For myself, I have been favorably inclined to the theory that the convulsions are due to anæmia of the brain, resulting from acute spasm of the cerebral vessels. If that theory is true, we can readily see how veratrum viride acts by relieving the spasm.

OFFICERS FOR THE ENSUING YEAR.

President, Dr. Robert Battey, of Rome, Georgia. *Vice-Presidents*, Dr. James R. Chadwick, of Boston, and Dr. A. Reeves Jackson, of Chicago. *Secretary*, Dr. Joseph Taber Johnson, of Washington. *Treasurer*, Dr. Matthew D. Mann, of Buffalo. *Council*, Drs. Frank P. Foster, of New York, C. D. Palmer, of Cincinnati, James B. Hunter, of New York, and R. Stansbury Sutton, of Pittsburgh.

The following new members were elected: Drs. Howard A. Kelly, of Philadelphia, Cornelius Kollock, of South Carolina, Bache McE. Emmet, of New York, and H. T. Hanks, of New York.

The report of the Committee of Conference with reference to the formation of a Congress of American Physicians and Surgeons was received, but the recommendations of the joint committee were *not* adopted.

The next meeting of the Society will be held in Boston, beginning the third Tuesday of September, 1888.

The Society then adjourned.

NEW YORK STATE MEDICAL ASSOCIATION.[1]

THIRD DAY. — MORNING SESSION.

The Treasurer, in his report, said there was a balance of $240, in addition to a building fund of $465.

ADDRESS ON MEDICINE.

Dr. John Cronyn, in this address, took a general view of the field of medicine, referring to the part played by special departments in bringing it to its

[1] Concluded from page 365.

present degree of perfection. It were well if those who entered upon the study of medicine were selected from among those who had already been trained in letters and arts. They should be inspired with a deep reverence for their profession, and a keen sense for its awful responsibilities.

COLD AS A THERAPEUTIC AGENT.

DR. B. L. HOVEY made brief allusion to the use of cold as a therapeutic agent in the past, and recited some cases of different affections in which he had found it of value, especially in asthenic fevers. The practitioner should be extremely cautious in selecting his subject, and the stage of the disease, for its trial. The temperature of the bath, when the bath is employed, should vary; but, as a rule, it should not be less than 65° or 70° F., and, in general, the patient should not be kept in it more than seven to ten minutes. Among the affections in which he had employed cold in some form with benefit, were typhoid fever, heat-stroke, gastritis, hæmatemesis, external hæmorrhage, uterine hæmorrhage, Bright's disease, etc.

THE SMALL-POX IN BROOKLYN; DEFECTIVE ISOLATION AND DEFECTIVE VACCINATION.

DR. NELSON L. NORTH said, in this paper, that the whole recent epidemic of small-pox in Brooklyn, extending over a period of more than one year, had been the result of one concealed case, in the person of a Polish emigrant who had landed at Castle Garden. In criticising the Brooklyn system of vaccination and isolation, it was not because he considered it worse than others, but because he was better acquainted with it. Unfortunately, politics sometimes meddled with sanitation. As remedies, he suggested the passage of more exact and definite laws having reference to the control of patients with contagious diseases, as well as universal and stringent enforcement of laws and ordinances already in existence. Treat small-pox patients more humanely, banish the small-pox hospital, which he regarded as an element of barbarism. There could be isolation, with good nurses, good physicians, well enough paid that they could stay by their patients, take care of them, give them rational treatment, and not leave them to live or to die, as the case might be. The records showed that a greater proportion of those sent to the hospital died than of those who took the risks, concealed themselves, and remained at home, and people believed that some were sent to these pest-houses who had not the disease, there acquired it, and died. It was no wonder that friends tried to conceal their sick from the officers of the law.

Dr. Nelson then discussed the importance of thorough vaccination with pure, fresh matter.

DR. HENRY C. VAN ZANDT then read a paper entitled

SPECIALISTS,

in which he deprecated the tendency for physicians to limit their practice and their knowledge to a single class of diseases. The general profession, he said, had to bear all the sins of all the specialists. It was too common for the unsuccessful general practitioner to become a specialist.

REPORT OF THE NOMINATING COMMITTEE.

The Committee on Nominations reported, for President, Dr. John Cronyn; also a Vice-President and a member of the Council from each of the several districts. The report was accepted, and the gentlemen named elected.

DR. THOMAS MANLEY, of New York, then read a paper on

EPITHELIOMA OF THE VULVA.

The books scarcely referred to epithelioma of the vulva, yet he thought the affection could not be so rare, for he had seen two cases within five years. In both he had operated, with the result of limiting the progress of the disease.

THIRD DAY. — AFTERNOON SESSION.

DISCUSSION ON PLACENTA PRÆVIA.

DR. GEORGE TUCKER HARRISON, of New York, opened the discussion with a paper, in which he, first, alluded to the importance of the study of the behavior of the cervix in the latter part of gestation, and during labor. The older views seemed to have been established on solid basis, but, recently, the arguments brought forward by Bandl seemed to overthrow these in considerable part. The uterus was differentiated into the contracting and thickening upper part, and expanding and thinning lower uterine segment and cervix. During labor, the lower uterine segment was essentially passive, the upper part exhibiting active contractions, the boundary between the two being denominated by Schroeder as the ring of contraction.

The all-important symptom of placenta prævia was, of course, the hæmorrhage, the source of the bleeding being the placental site, and the cause being the separation of the placenta. In treatment, the important problem to solve was to guard the patient against two dangers: bleeding, first; sepsis, second. The special liability of women who were the subjects of placenta prævia to septic infection was explained by the lower situation of the placenta, and by the lacerations so frequently concomitant to this condition, the agent of infection being the examining finger of the accoucher. Anæmia further favored septicæmia.

In treatment, the bipolar method of version introduced by Braxton Hicks was advocated as the best means of fulfilling all the theoretical indications. Zweifel's method of avoiding perforation of the placenta in central implantation was especially commended.

The problem of the future should be to diminish the terrible sacrifice of the child. Zweifel's method might here help, as well as improvements in antiseptic procedures, enabling us to use the vaginal tampon, and rupture the membranes without perforation of the placenta.

IN CASES IN WHICH THE PLACENTA IS PRÆVIA, WHAT ANATOMICAL AND PHYSIOLOGICAL FACTS EXPLAIN THE HÆMORRHAGE OCCURRING DURING PREGNANCY, AND WHY IS HÆMORRHAGE UNAVOIDABLE DURING MISCARRIAGE OR LABOR?

This question was discussed by DR. C. C. FREDERICK and DR. ISAAC E. TAYLOR.

Regarding the anatomical and physiological facts to account for hæmorrhage in placenta prævia, Dr. Frederick reviewed prevalent opinions on the subject including those of Bandl, and said that as to hæmorrhage being unavoidable during labor or miscarriage, he thought it was not.

DR. TAYLOR said the obstetrician based his views upon the demonstrations of the anatomists and upon his own experience by touch during delivery. He had expressed his views based on observation in a brief

paper read before the New York Academy of Medicine, in 1862. He demonstrated by touch alone that the cervix uteri did not coalesce with, or become absorbed into the body of the uterus during the progress of gestation. The cervix had no special physiological function as had the body; it was passive, and remained so until the time of labor. It was prepared physiologically to dilate and expand to admit of delivery of the child, as the body of the uterus was prepared to contract and accomplish the delivery. The placenta is not physiologically related in the circulation of the cervix. The body of the uterus is the only true habitat for the placenta during gestation. The hæmorrhage taking place during labor when the placenta was before the head of the child occurred during diastole, and not during contraction of the uterus, and was from the uterus.

Dr. Darwin Colvin and Dr. S. B. W. McLeod discussed the second question.

IN THIS ANOMALY, WHAT IS THE SOURCE OF HÆMORRHAGE, AND WHAT IS THE MECHANISM OF ITS ARREST?

Dr. Colvin said authors differed in opinion as to the source of the hæmorrhage; he had no definite views, and would not devote much space to its consideration. He had had five cases of placenta prævia, and from his experience therewith, drew conclusions as to the proper treatment, which he thought should be to bring on labor, and not risk the life of the mother with the possible hope of saving the child. The responsibility was too great to temporize. He believed the life of the child was entirely secondary to that of the mother, and that an effort to save both in not bringing on labor, would oftener prove fatal to both.

Dr. McLeod said, in answer to the question proposed, that the source of the hæmorrhage was either the placenta, the uterine sinuses, or branches of the uterine artery or vein, or both, or all combined; but authors differed in their views on this subject. As to the mechanism of its arrest, not treatment, he confined himself to a few points. First, that the partial separation of the placenta be converted into total separation, and the hæmorrhage would then generally cease, the idea being to cut off the blood-supply from the uterus; it also gave opportunity for contraction and closure of the uterine sinuses. The tampon, by obstruction, could only temporarily delay the bleeding. Then there were hæmostatics, such as cold, ergot, etc.

Dr. W. T. Lusk discussed the question

IF PLACENTA PRÆVIA BE DIAGNOSTICATED DURING PREGNANCY, IS THE INDUCTION OF PREMATURE LABOR INDICATED?

If pregnancy had advanced to the seventh month, we should, as a rule, proceed to deliver, for the next hæmorrhage might prove fatal. Previous to the seventh month hæmorrhage usually leads to abortion, the management of which does not differ from the management of abortion occurring without placenta prævia. If hæmorrhage begins before the child is viable, there is little hope of saving it by delay. In most cases the first hæmorrhage is slight it should serve, as a warning. If the physician's suspicions are confirmed he should not leave his patient until she is secure. The practical results of the induction of labor in the hands of its advocates, speak effectually in its behalf. Strict antisepsis is a condition of success. Version is attended by serious loss of infantile life.

Dr. Rollin L. Banta and Dr. John Shrady discussed the question

DURING LABOR, WHEN THE PLACENTA IS PRÆVIA, WHAT MODE OF TREATMENT BEST SUBSERVES THE INTERESTS OF THE MOTHER AND CHILD RESPECTIVELY? IS THAT PLAN OF TREATMENT WHICH BEST CONDUCES TO THE PRESERVATION OF THE MOTHER'S LIFE, INCOMPATIBLE TO A CERTAIN DEGREE WITH THE CHILD'S INTERESTS?

Dr. Banta favored the method of Braxton Hicks, which had been most effectual in saving the mother's life in his practice. He had found less danger from hæmorrhage than from infection, although in his cases antisepsis was observed.

Dr. Shrady thought the statistics which gave the percentage of maternal deaths as one in three, had been overstated, while that of the infantile deaths had been underestimated: it should be eighty rather than sixty-five per cent. He could recall but four cases; they certainly did not belong to cases of central implantation. The watchword, deliver at all hazards, seemed in the days of his pupilage, to have been passed all along the lines of the profession. The best chances of the mother were in the direction of parturition, but in a given number of cases of cervical lateral attachment, the hæmorrhage may cease spontaneously. The interests of mother and child in no sense conflict.

Dr. John G. Orton and Dr. W. H. Robb discussed the fifth question

AFTER CHILD-BIRTH, IN PLACENTA PRÆVIA, WHAT THERAPEUTICAL MEASURES WILL MOST CERTAINLY GUARD AGAINST THE DANGERS OF HÆMORRHAGE AND SEPTIC INFECTION?

Dr. Orton called particular attention to the benefit derived from friction over the nipples, in the arrest of uterine hæmorrhage.

Dr. Robb would remove pillows from under the patient's head, secure firm and continued contraction of the uterus, would give by hypodermic injection fifty minims of Squibb's fluid extract of ergot; if this failed, throw hot carbolized water into the uterus. In two cases he was enabled to keep the uterus contracted only by faradization. In such a case he would suspect laceration of the cervix, and if the patient's condition admitted would repair it. To prevent infection thoroughly empty the uterus, secure firm contraction; it might be necessary to inject hot carbolized water; after this, pass iodoform up to the fundus. Lacerations should be disinfected.

ACUTE MANIA.

Dr. J. C. Hannan read the history of the case in which the question of diagnosis was difficult. The patient was a young man, and had rheumatic symptoms.

Dr. Charles S. Allen then related

A CASE OF INTRA-RECTAL LARVÆ, WITH GASTRITIS, IN AN INFANT.

The author gave the patient's symptoms, and said that in the passages were found peculiar objects, which on microscopical examination, resembled the larvæ from the blow-fly. He thought the source must have been the food ingested.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 20, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

MEMBRANOUS OR PSEUDO-MEMBRANOUS ENTERITIS.

THIS disease is looked upon as one of the curiosities of clinical medicine, not only from its uncertain etiology and pathology, but because, while not a common affection, it is, on the other hand, not so rare but that almost every practising physician, sooner or later, meets one or more cases of it. The unusual number of synonyms for it (some students of medical literature have found as many as thirty-six) is accounted for by the fact that, as it did not receive systematic description till the paper of Powell (1818), and each observer, more or less unfamiliar with what had been seen by others, gave a name of his own choice to what was practically his own independent discovery.

With all the cases that have been described of recent years, sufficient to put the tolerably constant symptomatology of the affection fairly upon clinical record, we are, unfortunately, ignorant as to the direct causation and pathology of the disease. That it occurs usually in women of a more or less neurotic tendency, and usually of middle age, is established. Of one hundred cases referred to by Wales in Pepper's "System of Medicine," four only occurred in males, of which two were children. He finds it alike rare in children, and in persons over forty-five years of age. Dr. J. B. Field, of Lowell, in a monograph which well reviews the subject up to the present date, has collected one hundred and eleven cases, in one hundred and six of which the sex was stated. Of these, twenty-one were males, eighty-five females. Of sixty-nine patients, the ages were given, and, of these, the following number belonged respectively to each consecutive decade of life: six, three, seven, eighteen, twenty, twelve, two, one, the greatest frequency, as will be seen, being from forty to fifty years of age.

Dr. Wales, while failing to throw light on the pathology of the disease, yet destroys some previous theories as to its morbid anatomy. His chemical tests showed the exfoliated membranes to be devoid of both fibrin and albumin, and to consist essentially of mucin, in which respect they differ from ordinary croupous and diphtheritic exudates. The microscopical, as well as the chemical characters of the membranes, show them to differ from the exudates of other diseases of the alimentary mucous membrane, and to consist of a production of the muciparous glands (follicles of Lieberkühn).

Are we to consider, as did some of the older observers, that the enteric exudate is the product of a merely local inflammation? or may we look upon it as a derangement of secretion, having its cause in some undefined derangement of the nervous system? That the latter is more likely to be the case seems to us to be shown by certain coincident affections that are observed. We have ourselves seen a patient presenting, at various times, membranous discharges from bowels, bladder, and womb. Now, although the anatomical constitution of the exudate in membranous dysmenorrhœa is entirely different from that in enteritis (as, indeed, must be the case from the difference in the nature of the lining membrane from which are thrown off the two exudates), yet there is reason for supposing that the uterine exudate is a decidua in some way analogous to that of pregnancy, and influenced by the same nervous supply as the ovaries; and it is certainly remarkable, in view of the infrequency of both affections, that six of the cases of membranous enteritis collected by Dr. Field presented, also, uterine casts, or pseudo-membranous dysmenorrhœa.

Indeed, may we not go a step further, and suppose that the roughness of skin so often seen in ill-nourished neurotic patients, and noted by Wales as an accompaniment of this very affection, is dependent on a derangement of the same centres of nervous supply as, by their impairment, have caused the exfoliation in the intestine and the uterus? This view coincides with that of several of the most recent authorities on the subject. Da Costa saying, for instance, that the "depressed general condition, the severe pain, the recurring character and obstinacy of the complaint, the frequent association with uterine disease; the constancy of signs of disordered nervous manifestation, the association, often, with *similar discharges from other outlets*, point to a deeper, more general cause than an enteritis or morbid condition of the intestinal mucous follicles."

If membranous enteritis, then, is an intestinal neurosis, we can understand something of the failure of treatment, so much of which has been directed to the local lesion. Unsatisfactory as all treatment has usually proved hitherto, we have a hint of possible value in the neurotic nature of the affection.

GASTRALGIA.

GASTRALGIA (*cardialgia, gastrodynia, stomach-ache*) is generally regarded as a neurosis affecting the gastric nerves. Romberg distinguished two forms: one, which he called gastrodynia neuralgica, he held to be a hyperæsthesia of the gastric branches of the vagus nerves; the other, which he called neuralgia cœlica,

he regarded as a hyperæsthesia of the solar plexus. Henoch, however, regards this distinction as one that is inapplicable, and worthless in practice. Sawyer, in the *Lancet*, August 13, 1887, would call a case of gastralgia "one in which pain, deep-seated and paroxysmal, in or about the stomach, of a neuralgic or quasi-neuralgic character, is the leading symptom." This pain "must be unaccompanied by gastric or gastro-hepatic catarrh, or physical signs of structural disease either in the stomach or in its neighborhood." A diagnosis of gastralgia (which, of course, is only a symptomatic diagnosis) can only be continued "when repeated physical exploration fails to reveal any other coarser interpretation of the patient's suffering."

Romberg's description of an attack of gastralgia in its severest form has been regarded as typical: "A violent, contracting pain at the pit of the stomach supervenes suddenly, or after being preceded by a sense of oppression; it generally extends to the back; there is a sense of fainting; the face is fallen in; the hands and feet are cold; the pulse is small, cramped, and intermittent. The pain attains such a pitch as to cause the patient to scream out. The region of the stomach is either swelled and distended, like a ball, or, as is more frequently the case, it is drawn in, and the abdominal parietes are tense. It is common to find pulsation at the epigastrium. Pressure is not only well borne, but the patient frequently forces the pit of the stomach against some firm object, or compresses it with his hands. (This Dr. Sawyer regards as a very important diagnostic sign.) Sympathetic sensations occur in many instances in the thorax, under the sternum, or in the pharyngeal branches of the pneumogastric, while they are seldom met with in the superficial parts."

Gastralgia may occur at any age, though it is rare at the extremes of life, and it is most commonly met with in middle life, and in connection with the nervous temperament. Women are more subject to gastralgia than men, and, in the former, it is often due to anæmia, hæmorrhages, or prolonged uterine discharges. In man, gastralgia may be the result of overwork, sexual excesses, or masturbation.

In the treatment of gastralgia, Dr. Sawyer urges the pre-eminent utility of arsenic, which he alleges to be generally curative of this affection. He gives one-twenty-fourth of a grain of arsenious acid, made into a pill, with two grains of extract of gentian, thrice daily, between meals. The use of this remedy must be continued for a few weeks. In a case of moderate severity, he says, no other medicinal treatment is necessary. The gastralgic pains become less frequent and less severe, and recovery is steadily and surely attained. In severer cases, he uses some form of counter-irritation to the epigastrium, the volatile liniment, for instance. In the severest cases, vesication by a fly-blister is of service, the blistered surface to be kept raw with savine ointment. The diet should be generous. A dyspeptic regimen makes a case of gastralgia worse.

Dr. Sawyer gives some hints as to diagnosis which are worth remembering: "(1) Gastralgia is not a wasting disease. (2) It is not safe to diagnosticate cancer of the stomach till you can *feel* the cancer. (3) Do not diagnosticate ulcer of the stomach till you have *seen* blood from the stomach, either in hæmatemesis or melæna. You may take it as a clinical truth that pain arising in the stomach, when the organ is empty and relieved, by the ingestion of food, is almost pathognomonic of its nervous origin and nature."

THE VITAL STATISTICS OF MASSACHUSETTS FOR THE YEAR 1886.[1]

The Forty-Fifth Registration Report of Massachusetts, the first since the sanitary interests of the State were entrusted to a board of health, lunacy and charity, comes to us edited by the restored State Board of Health.

It appears that the year 1886 has been one in which the public health showed a marked improvement over that of the previous years since 1879, the birth-rate being greater and the death-rate less than those of any year within that period. During the year there were recorded 50,788 births, 18,018 marriages and 37,244 deaths, or 1,998 more births, 966 more marriages and 850 less deaths than in 1885. The excess of living births over deaths was 13,544, which is 2,848 more than that of 1855, and also greater than the increase of any year since 1860, except that of 1874. The approximate rates for the year were birth-rate, 25.69; marriage-rate (marriages), 9.12; death-rate, 18.85; excess of births over deaths, 6.84, or one child born alive to 39 persons, one person married to 55, and one death to 53 living persons, and a daily average of 139 births, 49 marriages and 102 deaths.

As compared with other countries we have a high marriage-rate, a low birth-rate and a low death-rate, the rates being smallest in the small country towns.

The average ratio of males to females among living births in Massachusetts, for a period of thirty-three years (105.7), corresponds quite closely with that of all Europe. The excess of children born of foreign parents over those of native parentage was 1,227, which was 316 greater than that of 1885, and also greater than that of any year since 1876, when the excess of births of foreign parentage was 1,800. The number born of mixed parentage was 9,299, which was 427 greater than that of 1885, and also greater than that of any previous year.

There were 1,796 still-births. The 1,034 illegitimate births indicate a ratio of 20.3 per 1000 as compared with 64 (from 29 in Russia to 152 in Bavaria) in Europe.

[1] Forty-Fifth Report to the Legislature of Massachusetts relating to the Registry and Return of Births, Marriages, and Deaths in the Commonwealth, for the Year ending December 31, 1886. Together with the Reports relating to the Returns of Libels for Divorce and to the Returns of Deaths investigated by the Medical Examiners, for the Year 1886. Prepared by the Secretary of the Commonwealth. With Editorial Remarks by Samuel W Abbott, M.D. Boston: Wright & Potter Printing Co., State Printers. 1887.

The marriage-rate for 1886 was .63 lower than the average for the past twenty years, and .71 higher than the average for the past ten years. Comparing the statistics of the last two decades, the rate for the former proves to be 2.69 greater than that of the latter period. There has been a decrease in the marriage-rates of nearly all European countries during the past twenty-five years, and also in four New England States having registration, — Massachusetts, Rhode Island, Connecticut and Vermont.

The whole number of divorces granted during the year was 601, which was 45 less than the number granted in 1885, and 105 more than the yearly average of the twenty years ending with 1886. Of the whole number, 125, or 20.8 per cent., were granted on account of adultery; for desertion 45.7; for intoxication 16.3; for extreme cruelty 5.3; for cruel and abusive treatment 10.3; and for neglect to provide maintenance 1.2. Four hundred and twenty-one, or 70.0 per cent. of the whole number, were granted on complaint of the wife. Of the divorces decreed on account of adultery, 53.6 per cent. were granted to women; for desertion, 61.1 per cent.; for intoxication, 85.7 per cent.

The infant mortality, 21.07 (percentage of deaths under one to total deaths) was greater than that of any year since 1875 (22.04) and also greater than the average of fifteen years from 1872 (20.94). The average age of all persons at death was 34 years, the extremes, excluding the two small island counties, being 48.63 in Barnstable County and 30.29 in Suffolk.

There has been, since 1876, an almost steady decrease in the ratio to all deaths, of deaths from so-called zymotic diseases (from 28.6 to 18.5). In constitutional diseases the change has not been so marked, 25.1 to 24.2; while in "local" diseases, there has been a nearly constant increase from 31.7 to 42, the more striking changes being shown in the first two of the following tables. The population increased from 1875 to 1885 by census from 1,651,912 to 1,945,141.

From 1867 to 1886, the reported death-rate from pulmonary consumption has decreased from 3.25 to 2.98 per 1000 of population, while from cancer in the same time, it has increased from 0.29 to 0.56. The very striking increase in mortality from brain disorders for the last six census years is shown in the third of the following tables:

DEATHS FROM PROMINENT "ZYMOTIC" DISEASES.

Years.	Dysentery.	Typhoid Fever.	Whooping-Cough.	Croup.	Diphtheria.	Measles.	Scarlatina.	Cholera Infantum.	Small-pox.	Total.
1877	580	814	369	544	2,634	135	467	1,267	26	7,496
1878	602	679	409	583	1,934	305	404	1,573	2	6,481
1879	372	637	302	539	1,744	19	859	1,349	8	5,830
1880	395	882	230	625	1,769	256	574	2,118	38	6,867
1881	360	1,072	247	677	1,706	230	397	1,861	47	6,567
1882	398	1,079	265	491	1,280	68	318	2,159	45	6,103
1883	336	860	197	530	1,024	321	575	1,941	5	5,796
1884	254	875	410	562	1,084	75	627	2,084	3	5,971
1885	253	768	184	520	1,003	313	587	1,532	19	5,499
1886	243	800	271	505	1,053	130	331	1,931	0	5,264

DEATHS FROM PRINCIPAL LOCAL DISEASES.

Years.	Apoplexy.	Paralysis.	Insanity.	Convulsions.	Heart Diseases.	Bronchitis.	Pleurisy.	Pneumonia.	Peritonitis.	Bright's Disease, Nephritis and other Kidney Dis.
1877	541	843	112	536	1,391	397	82	1,972	126	546
1878	562	895	152	562	1,509	548	80	2,171	104	634
1879	663	932	118	612	1,698	690	90	2,647	276	711
1880	746	933	142	705	1,822	780	98	3,076	270	723
1881	718	998	129	691	1,937	843	88	2,967	284	843
1882	706	1,047	153	687	2,025	867	102	2,932	307	900
1883	784	1,056	183	757	2,153	934	104	3,045	339	987
1884	857	1,119	166	702	2,117	949	65	2,646	307	1,032
1885	1,003	1,132	188	721	2,227	1,131	138	3,408	350	1,128
1886	973	1,173	151	709	2,469	1,020	100	2,836	320	1,161

Mortality-rates per 10,000 from —	1860.	1865.	1870.	1875.	1880.	1885.
Apoplexy, . . .	1.93	2.08	2.70	2.78	4.19	5.12
Softening of the brain, . . .	.36	.33	.58	.59	.68	.65
Paralysis, . . .	3.26	3.78	4.32	5.43	5.23	5.82
Insanity, . . .	.58	.59	.71	.71	.71	.96
Cephalitis and brain disorders, . . .	5.93	7.61	6.04	6.91	6.19	7.46
Totals, . . .	12.06	14.39	14.35	16.42	17.00	20.01

From ague and remittent fever the number of deaths reported in 1886 was 32, of which number 20, or 62.5 per cent., occurred in the five western countries having but 26 per cent. of the population. The greatest number, 8, occurred in Hampden county. Although serious epidemics have occurred in eastern Massachusetts in 1884, 1885 and 1886, they have thus far had but little effect upon the death-rate.

It is gratifying to learn that the improvement of later years in the proportion of deaths without reported causes of death continues, having reached, in 1886 the lowest percentage, namely, 1.21 of all deaths.

The returns of the medical examiners indicate that 1,378 cases were examined in 1886 as compared with 1,278 in 1885. There were 202 autopsies. Of the 1,378 deaths investigated 47 were from homicide, 157 from suicide, 678 from accident or negligence, 233 from apoplexy and heart disease, 54 from alcoholism. It is one of the small advantages of the new method that there is a considerable less expense involved in it than in the old coroner system.

The report is larger than usual, from additions to the editorial portion, and will well repay careful study.

MEDICAL NOTES.

— Private letters, published in New York, from Colon, state that there have been many deaths from yellow fever in the latter city, and the disease still prevails. Absolutely no precautions are taken to vents its spread. The city is filthy to a degree. Despite the constant presence of yellow fever, certain consuls grant clean bills of health to steamers trading with or touching at American ports. Advices from Belize,

British Honduras and Livingston, Guatemala, report several cases of yellow fever at both places.

Eighty cases of yellow fever had been treated at Tampa, Fla., up to October 14th, with twelve deaths. The citizens are aroused, and have organized and equipped a hospital. The case of fever at Palatka was that of a Tampa fugitive. There are no other cases in the place.

The Marine Hospital Bureau has received a dispatch, October 14th, from Dr. Porter, President of the Key West Board of Health, reporting his arrival at Tampa with four nurses. He says that the customary tests prove beyond all question that the disease is yellow fever. Deputy Collector Spencer telegraphs, under the same date, "There were three deaths last night, and several new cases to-day. The local authorities are at last acting and taking measures to disinfect."

—The local Health Councillor of Carlsruhe published under date of February 28, 1887, an analysis of "Warner's safe cure," which appears to have found a place in the shops of Germany. "It is," he says, "an infusion of liverwort flavored with oil of wintergreen, and containing a small quantity of saltpetre, glycerin and alcohol; to be taken along with this are pills made of aloes and coated with sugar."

— The Ameer Abdul Rahman is not a pleasant patient, at least according to the stories told in some of the Indian bazaars. It seems that that magnate has been recently suffering from an ulcer in the back. His physician prescribed some application, which, as is not infrequent in medical practice, had the result, for the time being, of increasing the pain. After a night of enhanced agony, the Ameer arose, sent for the luckless doctor, and had his head struck off there and and then.

— Bardach, in the *Annales de l'Institut Pasteur*, as quoted by the *Medical Press*, relates the case of a woman who was bitten by a rabid wolf. After the bite she ceased to suckle her infant. A small quantity of the milk was taken from the mother's breast and injected into the cranial membranes of dogs and guinea-pigs. All the animals injected were seized with the typical madness. The mother died, but the child that was taken from the breast after the bite still lives and appears perfectly healthy.

— We learn from the *Indian Medical Gazette* that a renewed attempt is to be made to grow ipecacuanha on the Nilgiri Hills, as this medicine is largely used in India for dysentery and other diseases, and a London medical paper reports that the stock in first hands in London, the chief emporium for the drug, was very low and would probably all be taken out of the market at an early date. The price also had risen very considerably, and it had become a matter of doubt whether the Government would be able to purchase the quantity annually required for India. Experiments have been made for some years in the growth of the plant in the Botanical Gardens at Utakamund and elsewhere, which have shown that, though not difficult to propagate, it is by no means easy of culture, and can only be successfully grown in a limited area, possessing suitable climatic conditions. It is considered improbable that the cultivation would be taken up to any extent by private individuals, although its price would make it very remunerative. The Government has, therefore, on the recommendation of the Surgeon-General and the Government Botanist, decided to take up the cultivation on its own account on a comparatively small scale, and the Government Botanist has been directed to plant out at Nilambar all the plants which he can procure at present. Before, however, undertaking the cultivation on a larger scale, the Government hope that private enterprise may be induced to come forward.

BOSTON AND NEW ENGLAND.

— The Berkshire District of the Massachusetts Medical Society, celebrates by a dinner October 27th, the one hundredth anniversary of the formation of an association for the improvement of the art of Physick. The dinner occurs at the American House, Pittsfield, Mass., October 27th, at 1.30 P.M.

— The extra-hospital training school for nurses at Waltham, Mass., of which an account has already appeared in our columns, has developed into a hospital, to be known as the Waltham Cottage Hospital. It was formally opened October 10th. Patients received will secure the best of care at a very small price, and, when the circumstances are known to require it, a still smaller sum will be charged, and, indeed, nothing at all, if it shall seem advisable to the Trustees. The services of the physicians connected with the hospital are furnished, but, if a patient shall so desire, those of any other physician may be had. The hospital and training school will be, as in the past, under the immediate care of Miss May Hackett, to whose zeal and energy much of its already great success it due. The support of the institution will still be, in large part, dependent upon contributions from those benevolently inclined. Collections in aid of the hospital were taken in most of the local churches the last two Sundays.

— A large number of horses in Cambridge were, some days ago, adjudged by the Cattle Commissioners to be affected with glanders. A veterinary employed by the Railroad Company declares that the disease is not glanders, but "malaria," induced, he says, by the conditions obtaining in the low flats adjoining the stables. Other veterinaries employed by them, while not agreeing with the malaria theory, are said not to believe that at most over a dozen of the 169 horses confined as being suspicious cases, have glanders. One day, last week, the Cattle Commissioners examined ninety-five horses in the Summer Street (Somerville) stables of the Cambridge Railroad Company, and confined eleven of them. The next day, they re-examined the horses confined, and also the horses quarantined in the Eighth Street (East Cambridge) stables of the Company, and kept them nearly all in confinement.

NEW YORK.

— The twelfth annual commencement of the Training School for Society of the Charity, Maternity, and Infant's Hospitals, on Blackwell's Island, was held October 12th. There were sixteen graduates, and the diplomas were presented by Dr. Alexander W. Stein, President of the Medical Board of Charity Hospital. Dr. Thomas H. Allen presented the prizes, and addresses were made by the Rev. Alexander Mackay-Smith, Dr. Robert W. Taylor, and others. An informal reception and luncheon were given their guests by the pupils of the school, and in the evening a social entertainment, with dancing and refreshments, took place under the auspices of the Medical Board.

— At a meeting of the Society of Medical Jurisprudence and State Medicine, held October 14th, Dr. F. N. Brill read a paper entitled, "Pasteur's Fiasco, and the British Parliamentary Report," in which he narrated the experiments made by himself and Dr. Spitzka, in which it is claimed that all the symptoms of rabies produced by Pasteur's inoculations in the rabbit and dog, can be caused by injecting various innocuous substances under the dura mater of these animals.

— Dr. H. G. Piffard has devised a method of taking instantaneous photographs at night by the light of a flash of a pistol charged with gun-cotton and powdered magnesium, and gave a practical demonstration of its use at a meeting of the Society of Amateur Photographers held October 11th.

— Dr. Henry Cook, the oldest and one of the most prominent physicians in Suffolk County, died at Sag Harbor, Long Island, October 9th. He was born in England, in 1814, but for more than forty years has resided in Sag Harbor, where he was most highly esteemed by the entire community.

— No new cases of cholera have developed among the *Alesia's* passengers quarantined on Hoffman's Island, since October 7th. The quarantine is still very strictly enforced, and will not be raised until all danger of infection is over.

Miscellany.

BOSTON DISPENSARY.

THE statistics of this institution for the year ending September 20, 1887, are as follows:

The number of new patients treated at the central office is 19,139, classified as follows:

Medical Department.—Men, 2,722; women, 3,991; children, 2,690; total 9,403.

Surgical Department.— Men, 1,398; women, 810; children, 525; total, 2,733.

Skin Department.— Men, 465; women, 382; children, 207; total, 1054.

Department for Diseases of the Nervous System.— Men, 398; women, 377; children, 64; total, 839.

Department for Diseases of Women.— Women, 553; total, 553.

Department for Diseases of the Throat and Nose.—Men, 504; women, 557; children, 425; total, 1,486.

Department for Diseases of the Eye. — Men, 66; women, 151; children, 118; total, 335.

Department for Diseases of the Ear.— Men, 130; women, 167; children, 171; total, 468.

Department for Diseases of the Genito-Urinary System. — Men, 769; women, 3; children 2; total 774.

Department for Diseases of the Rectum.—Men, 67; women, 46; children, 3; total, 116.

Orthopedic Department. — Men, 14; women, 20; children, 74; total, 108.

Dental Department. — Men, 276; women, 397; children, 597; total, 1,270.

The number of visits made by patients, old and new, at the Central office is 42,489, classified as follows: Medical, 18,160; surgical, 24,329; total, 42,489. The number of patients treated in the Districts is 13,072, including 315 cases of midwifery, classified as follows: Men, 1,997; women, 4,527; children 6,548; total, 13,072. The results of treatment in the Districts are as follows:

Discharged, cured or relieved	11,759
Removed to Hospitals	967
Died	331
Remaining under Treatment	66
	13,123
Under treatment at last annual report	51
	13,072
The number of patients treated at the Central Office and in the Districts is	32,211
Number of cases of midwifery attended during the year	315
Number of cases of midwifery attended since July, 1856	5,039
Whole number of patients since October, 1796	963,555
Whole number of patients since July, 1856,	844,752
Average daily attendance at Central Office	138
Largest number present any one day, May 9th	242
Smallest number present any one day, December 7th	55
Number of recipes put up at Central Office during the year	46,572
Number of house recipes	38,198
Number of district recipes	8,374
Largest number of recipes put up in one day, May 9th	280
Smallest number of recipes put up in one day, December 5th	66
Number of paid recipes	43,540
Number of free recipes	3,032
Number of paid dental patients	1,152
Number of free dental patients	93

The list of medical officers for the ensuing year is as follows:

Surgeons: Drs. J. Foster Bush, George H. Monks, Edward O. Otis, William M. Conant. Physicians: Drs. Robert Disbrow, Joseph P. Oliver, John Dixwell, Thomas M. Rotch, Claudius M. Jones, Harold Williams, James J. Minot, George M. Garland, Edward M. Buckingham, Vincent Y. Bowditch, William

C. Emerson, Robert B. Dixon, Russell Sturgis, Rufus A. Kingman, Thomas F. Sherman, James S. Howe, Howard M. Buck, Frederic M. Briggs.

Department for Diseases of the Skin.—Physicians: Drs. Francis B. Greenough, Abner Post. Department for Diseases of the Nervous System. — Physicians: Drs. William N. Bullard, Philip C. Knapp. Department for Diseases of Women.— Physicians: Drs. Francis H. Davenport, John W. Elliot, John B. Swift, George G. Hayward. Department for Diseases of the Throat and Nose. — Physicians: Drs. Thomas A. DeBlois, John W. Farlow, Edward W. Warren, Frederick M. Turnbull. Department for Diseases of the Eye. — Physician: Dr. William D. Hall. Department for Diseases of the Ear. — Physicians: Drs. George A. Leland, Henry L. Morse. Department for Diseases of the Genito-Urinary System. — Physicians: Drs. George H. Tilden, Francis H. Watson, Hayward W. Cushing, Gardner W. Allen. Department for Diseases of the Rectum.—Physicians: Drs. Walter J. Otis, William D. Hodges.

Obstetric Department.—Physician: Dr. Charles M. Green.

Orthopedic Department. — Physician: Dr. Royal Whitman.

Dental Department. — Dentist: Joseph E. Waitt, D.M.D.

District Physicians: No. 1. Dr. Willis B. McMichael. No. 2. Dr. Henry Jackson. No. 3. Dr. Charles W. Townsend. No. 4. Dr. George G. Sears. No. 5. Dr. John A. Jeffries. No. 6. Dr. George E. Richards. No. 7. William F. Temple. No. 8. Winfied B. Bancroft. No. 9. George Haven.

Apothecary: Frederick H. Dudley. Assistant Apothecary: Joseph S. Lang.

WILLIAM H. H. HASTINGS, M.D., *Supt.*

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 8, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 1,551: under five years of age 562; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 284, consumption 186, lung diseases 125, diphtheria and croup 100, diarrhœal diseases 89, typhoid fever 43, malarial fever 23, scarlet fever 14, whooping-cough nine, cerebro-spinal meningitis five, measles one. From malarial fever, New Orleans seven, Brooklyn and Baltimore five each, District of Columbia two, Philadelphia, Nashville, Charleston and Newton one each. From scarlet fever, Brooklyn six, Somerville and Chelsea two each, Philadelphia, Boston, Baltimore and Nashville one each. From whooping-cough, Philadelphia four, Brooklyn, Baltimore, Pittsburgh, Nashville and Somerville one each. From cerebro-spinal meningitis, Baltimore, Pittsburgh, Milwaukee, Somerville and Haverhill one each. From measles, Milwaukee one.

In the 23 cities and larger towns of Massachusetts with an estimated population of 1,029,379, the total death-rate for the week was 20.71 against 19.26 and 23.31 for the previous two weeks

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending September 24th, the death-rate was 16.2. Deaths reported 2,872: infants under one year of age 765; diarrhœa 185, scarlet fever 72, whooping-cough 61, fever 54, diphtheria 35, measles 29, small-pox (Sheffield) four.

The death-rates ranged from 10.0 in Derby to 26.4 in Blackburn; Birmingham 14.5; Bradford 15.8; Hull 19.3; Leeds 16.9; Leicester 13.8; Liverpool 18.7; London 14.4; Manchester 23.5; Newcastle-on-Tyne 20.9; Nottingham 13.5; Sheffield 19.1.

In Edinburgh 17.3; Glasgow 17.7; Dublin 30.6.

The meteorological record for the week ending October 8, in Boston, was as follows, according to observations furnished by Sergeant O. B. Coie, of the United States Signal Corps: —

Week ending Saturday, Oct. 8, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIESOF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 8, 1887, TO OCTOBER 14, 1887.

ALEXANDER, CHARLES T., lieutenant colonel and surgeon. Relieved from duty as attending surgeon and examiner of recruits at St. Louis, Mo., and ordered for duty at Fort Meade, Dak. S. O. 235, A. G. O., October 8, 1887.

CUNNINGHAM, T. A, captain and assistant surgeon. Died October 12, 1887, at Fort Lewis, Col.

CHANGE OF STATION.

HALL, WM. R., captain and assistant surgeon. From Davids Island to Fort Custer, Mont.

PRICE, C. E., captain and assistant surgeon. From Fort Custer to Fort DuChesne, U. Ter.

SUTER, WM. N., first lieutenant and assistant surgeon. From Washington Barracks to Fort McKinney, Wyo.

WEISEL, D., captain and assistant surgeon. From Fort McKinney to Fort Sill, Ind. Ter.

HORTON, S. M., major and surgeon. From Fort Riley to Fort Adams, R. I.

BACHE, D., major and surgeon. From Fort Adams to Fort Riley, Kans.

KIMBALL, J. P., major and surgeon. From West Point to Fort Elliot, Tex.

NEWTON, R. C., captain and assistant surgeon. From Fort Elliot to David's Island, N. Y. H.

HEIZMANN, C. L., major and surgeon. From Fort Ontario to West Point, N. Y. S. O. 232, A. G. O., October 5, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING OCTOBER 8, 1887.

IRWIN, FAIRFAX, passed assistant surgeon. Granted leave of absence for twenty-five days, October 5, 1887.

GUITERAS, JOHN, passed assistant surgeon. Granted leave of absence for seven days, September 28, 1887.

NORMAN, SEATON, assistant surgeon. Upon expiration of leave of absence to rejoin station, New York, October 4, 1887.

SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY. — A stated meeting will be held at Rockland Hall, 2343 Washington Street, Roxbury, on Tuesday, October 25, 1887, at 2 P.M. The Board of Censors will meet at 1 P.M. Order of Business: Reading of Records; Reports from Committees; Election of Nominating Committee; Incidental Business; Communications.

S. ALLEN POTTER, M.D., *Secretary.*

DEATH.

Died at Duxbury, Mass., October 15, 1887, James Wilde, M.D., M.M.S.S., aged seventy-five years.

BOOKS AND PAMPHLETS RECEIVED.

Surgical Relations of the Ileo-Cæcal Region. By J. Mc F. Gaston. (Reprint.)

Pathology, Diagnosis and Treatment of Perforation of the Appendix Vermiformis. By J. Mc F. Gaston, M.D. (Reprint.)

Persistent Vomiting during Labor Relieved by Anæsthesia. By Samuel C. Busey, M.D., of Washington, D.C. 1887. (Reprint.)

Transactions of the American Otological Society, Twentieth Annual Meeting. Pequot House, New London, Conn., July 19, 1887. Vol. 4, Part 1.

Transactions of the Medical Society of the State of West Virginia. Twentieth Annual Session, held at White Sulphur Springs, July 13, 14, and 15, 1887.

The Burton Case. By W. Thornton Parker, M.D. (Munich), Newport, R. I., Medical Examiner 3d District, R. I., Member of the American Public Health Association, etc. 1887. (Reprint.)

Pathology, Diagnosis and Treatment of Perforation of the Appendix Vermiformis. By J. McF. Gaston, M.D., Professor of Surgery, Southern Medical College, Atlanta, Ga. 1887. (Reprint).

Ovarian Tumors, and Remarks on Abdominal Surgery with the Results of Fifty Cases. By Edward Borck, A.M., M.D., Professor of Surgery, etc. Second Revised Reprint Edition. St. Louis, Mo. 1887.

A Paper on Imported Carlsbad Mineral Waters and Sprudel Salz. By A. L. A. Toboldt, M.D., Assistant Demonstrator of Pharmacy, University of Pennsylvania, Editor of the "Medical Clippings and New Chemicals," etc.

Biology of Tumors. A Lecture delivered at the College of Physicians and Surgeons, Chicago, Ill. By N. Senn, M.D., Ph.D., Professor of Principles and Practice of Surgery and of Clinical Surgery in the College. 1887. (Reprint.)

Massage: Principles and Practice of Remedial Treatment by Imparted Motion. Mechanical Processes. By George H. Taylor, M.D., Author of "Health by Exercise," "Health for Women," "Pelvic and Hernial Therapeutics," etc. New York: John B. Alden. 1887.

Successful Removal of Two Osteomata of the Orbit: One originating in the Frontal, and the other in the Ethmoidal Cells: with a History of Osteomata of the Neighboring Pneumatic Cavities of the Orbit. By Joseph A. Andrews, M.D., Ophthalmic Surgeon to Charity Hospital, New York. 1887. (Reprint.)

Differential Diagnosis. A Manual of the Comparative Semeiology of the more Important Diseases. By F. DeHavilland Hall, M.D., Assistant Physician Westminster Hospital, London. Third American Edition thoroughly revised and greatly enlarged. Edited by Frank Woodbury, M.D., etc. Philadelphia: D. G. Brinton. 1887.

N. W. Ayer & Son's American Newspaper Annual for 1887, containing a carefully prepared List of all Newspapers and Periodicals in the United States and Canada, arranged by States in Geographical Sections, and by Towns in Alphabetical order. Giving under this head the name of the paper, the issue, general characteristics, year of establishment, size, subscription price and circulation, also the names of Editors and Publishers, and the street address (when known) in all cities of above 50,000 population. Enumerating the various Press and Editorial Associations throughout the United States and Canada, together with lists of their Officers, etc.

Original Articles.

CONGENITAL TALIPES EQUINO-VARUS.[1]

BY CHARLES L. SCUDDER.

DESCRIPTIVE ANATOMY.

Case I. The fœtus from which this specimen was obtained was born at term, measured forty-eight centimeters in length, weighed three thousand, nine hundred and forty grammes, and presented the following pathological appearances: A posterior hydrencephalocele, three small supernumerary spleens, a fleshy knob upon the end of the tongue, a cleft uvula and epiglottis, a fibrous appearance at the edge of the liver, six fingers upon each hand, six toes upon each foot, clubbed hands, and double talipes equino-varus.

EXTERNAL CHARACTERS.

Six toes are present. The anterior portion of the foot is turned downward and inward. The sole of the foot looks inward, and a little backward and upward. The inner border looks upward. The outer border looks backward. The heel is pointed and slightly raised. The tuberosity of the os calcis can be felt with difficulty. The internal malleolus is less prominent than usual. The external malleolus is also less distinctly marked than in a healthy foot. The length of the foot is a little shortened. The dorsum of the foot is more or less irregular. The foot cannot be restored to its natural form and position by manipulation.

CHANGES FOUND UPON DISSECTION.

The bones. — Os calcis. This bone occupies an oblique position, the tuberosity being drawn upward by the muscles of the tendo Achillis, so that it is in close proximity to the fibula side of the leg. Adams describes a lateral change in direction, the anterior extremity of the bone being directed obliquely forwards and inwards, and its tuberosity inclined, also, toward the fibula side of the leg. It seems unnecessary that there should be any such lateral deviation in order to put the tuberosity of the os calcis in close proximity to the fibula. The astragalus is displaced from its articulation forward, and thus carries the os calcis with it. The normal position of the tuberosity of the os calcis is almost directly behind the fibula. Therefore, when carried forward by the displaced astragalus, it must be brought into closer proximity to the fibula.

I notice a slight tendency to arching of the os calcis in the direction of its length, the convexity being outwards. The articulating surface, with the cuboid, is unaltered in direction.

The astragalus. The neck of the astragalus is turned inward, instead of being straight.

The external lateral articular facet is extended forward a little out of the joint.

I cannot state as to the relative degree of development of the internal and external facets, for the bones are articulated.

The Italian anatomist, Scarpa, in 1803, describing the changes in the bones in his memoir upon congenital club-foot, does not admit any malformation of this bone, other than that arising from a persistence of the deformity through several years' use.

Dr. Little, an English anatomist and surgeon, after the dissection of thirty specimens of varus, agrees, with Scarpa, that the astragalus is scarcely altered in position or in form.

In 1852, Adams, an English surgeon, described very important alterations in the astragalus. In the specimen under consideration, the bone is tilted a little downward and forward, and slightly displaced from its socket, the latter fact allowing the os calcis to come forward to the fibula, as mentioned above.

Adams finds that the astragalus is rotated outward, so as to bring the external lateral facet firmly in contact with the fibula. There is no evidence of this rotation in the present specimen.

Adams finds, too, that the line of the ankle-joint, when opened from the front, presents an oblique direction upward and outward, corresponding to the rotation outward of the astragalus.

In the specimen, there is a slight inclination of the line of the joint upward and outward, toward the fibula. There is no rotation of the astragalus according to which Adams explains the deviation in the line of the joint.

Figure 1 is from a section through the malleoli of the left foot of the fœtus from which this dissected specimen comes. The foot is in the position of equino-varus.

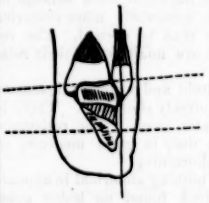

Fig. 1.

Fig. 2.

Figure 2 is from a section through the malleoli of an ankle from a fœtus of six months. The position of the foot is normal. The inclination of the line of the joint is slightly upward and outward. By comparing these figures, it is seen that the inclination of the line of the joint upward and outward is no greater in the varus foot at term than in the normal fœtal foot. In making comparisons, feet of the same age should be used, if it is possible. The above comparison is a legitimate one, however, for the difference in age is but three months, the one being normal and fœtal, the other being a decided varus, and at term.

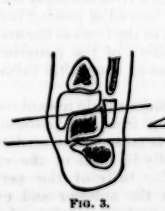

Fig. 3.

Fig. 4.

Rupprecht has made sections similar to the above. One was through the ankle of a new-born child; the other was through the same parts of a club-foot of two-and-one-half years. See Figures 3 and 4. He finds that the normal ankle-joint line is inclined a little

[1] The Boylston Prize Paper of the Boylston Medical Society of Harvard University for the year 1887.

upward and outward, while the line of the club-foot joint is very much so inclined.

After looking at the joints of the above specimens, and at a dissected case of acquired club-foot, a drawing of which I have not made, my conclusions are:

(1) That there is a normal inclination of the line of the ankle-joint upward and outward toward the fibula. (2) That, in moderate cases of congenital equino-varus, the line of inclination of the ankle-joint is about as in a normal ankle. (3) In severe cases, and especially in those in which the foot has been used in walking, the inclination of the line of the ankle-joint is greater than in moderate cases of varus.

The scaphoid is drawn inwards and upwards, and lies in close proximity to the internal malleolus.

The cuboid. Mr. Adams thinks that a displacement of this bone in the infantile varus is unnecessary, and he does not find any. In this specimen, the outer edge of the cuboid is depressed from its normal relation to the os calcis. In fact, I think the same change in position has occurred here that Mr. Adams describes under adult varus, a rotation of the cuboid upon its calcaneal articulation.

The malleoli. The diminished prominence of the internal malleolus noticed before dissecting is found to be due to the presence of the navicular bone beneath it. The external malleolus is apparently more posterior to the internal malleolus than is normal. The remaining bones of the foot are unaltered in their relations to each other.

The ligaments. The deltoid and posterior ligaments of the ankle-joint are adaptively shortened. There is no shortening of the plantar fascia. The resistance to complete reduction is due, in great measure, to ligamentous rigidity and shortening.

The muscles. There is nothing abnormal in appearance. Parker and Shattock found no lesion upon microscopic examination of muscular tissue from cases of congenital talipes equino-varus.

The tendons. All of the tendons in front of the ankle-joint are inclined to the inner side of the leg. The tendons behind the inner malleolus preserve their normal relations.

The tendons that normally are behind the external malleolus lie upon, and in front, of that bone. The tendon of the tibialis anticus is much shorter than usual, and is removed to the inner side of the joint. The tendon of the extensor proprius pollicis lies along the inner side of the first metatarsal bone. The tendon of the tibialis posticus is very tense, and, in passing to its insertion, goes directly down from the inner malleolus, and only a little forward, instead of passing beneath it downwards and forwards, to the front of the malleolus.

This change in the position of the posterior tibial tendon is noted in all cases of congenital varus and is of importance.

The tendo Achilles inclines a little toward the fibula and is slightly more distant from the posterior tibial vessels than normal. It is tense. The tendon of the peroneus longus lies wholly in front of the external malleolus. The muscular belly of the peroneous brevis completely covers the anterior and external surfaces and in part the posterior surface of the external malleolus. The peroneous brevis, therefore, lies beneath the tendon of the peroneous longus. The tendons of the peroneous brevis and longus, both lie in front of the peroneal tubercle of the os calcis. The vessels and nerves are in their normal relations.

CASE II. A double congenital talipes equino-varus.

The right foot.— External characters. The toes point directly inward and upward. The dorsum of the foot looks forward. The sole of the foot looks backward. The internal malleolus can with difficulty be felt. The deformity cannot be completely corrected.

After dissection. The muscles and tendons preserve their normal relations. The tibialis posticus and the tendo Achilles are very tense. The peronei are behind the external malleolus. When the tendons are all cut the deformity persists. Upon forced reduction the dorsal ligaments wrinkle and loosen, and the plantar and internal lateral and posterior ligaments are rendered very tense.

The bones. The tibia and fibula in their lower one-third are bent antero-posteriorly, with the convexity forward. The tibia is bent slightly more than the fibula. The internal malleolus is found to have been partially concealed by the proximity to it of the scaphoid bone. This close relationship is maintained by the tibialis posticus muscle and more particularly by the adaptively shortened ligaments, astragalo-scaphoid, etc. The long axis of the scaphoid bone (see Fig. 5) "de" is no longer transverse to the long axis of the leg but is perpendicular to the horizontal plane of the table.

FIG. 5.

The astragalo-scaphoid articulation is correspondingly altered. Its plane is almost parallel with the plane to the inner side of the leg. The os calcis is rotated outward to an extreme degree. The perpendicular plane of the bone is almost horizontal with the plane of the table instead of being at right angles to it. (See Fig. 6).

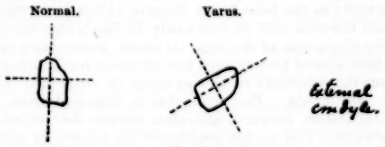

FIG. 6.

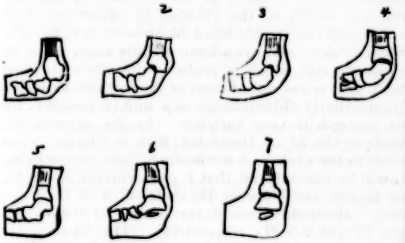
The attachment of the tendo-Achilles is approximated to the posterior ligament of the ankle-joint. The foot is in the position of a marked equinus. No part of the articular facet of the astragalus with the scaphoid, is uncovered of the scaphoid. The head of the astragalus looks forwards and inwards. The tibio-astragaloid facet of the astragalus is farther back than usual, the anterior portion of the facet being extruded a little from the joint. The cuboid bone has rotated with the os calcis and not upon it.

The reduction of the equinus is completed upon cutting the posterior ligament of the ankle-joint. It is questionable how much the tendon of the flexor longus pollicis muscle resists the reduction of the equinus. The calcaneo-cuboid and scaphoid ligaments offer considerable resistance to the reduction of the varus.

Left foot of the above specimen. The same anatomical conditions exist here as in the preceding specimen. The scaphoid bone is in contact with the inner malleolus.



Case III. An adult equino-varus in the Warren Museum of the Harvard Medical School shows well the altered relations of the bones of the foot. (See Fig. 7). The astragalo-scaphoid articulation is divided into two distinct facets (dc and cb) separated from each other by a definite ridge (at c). A bursa (at x) probably existed between the inner extremity of the scaphoid and the body of the astragalus and the internal malleolus. The articular surface of the astragalus with the scaphoid looks inward.

Fig. 7.

In attempting to reduce this dissected specimen to a normal position, I found it impossible. The attempt stretched the ligaments enough to allow the tarsal bones to come into contact. Further movement between the bones was blocked, and all the ligaments on the inner side of the foot were rendered tense.

The following series of figures, one to seven inclusive, are taken from antero-posterior sections of a normal fœtal ankle-joint. They show the relation of the astragalus to the lower end of the tibia in a normal foot.

Comparing these figures with Figure 11, the differences in the relations of the astragalus and tibia in normal and varus feet is very clearly seen.

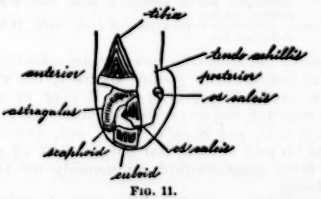


Fig. 11.

Figure 11 shows the relation, in a case of equino-varus, of the anterior portion of the body and neck of the astragalus to the lower articular surface of the tibia. The astragalus is depressed from the joint.

(To be continued.)

— Arsenious compounds added to putrefying matter are, according to certain recent researches of Hamburg, converted into arseniuretted hydrogen; which escapes as gas. This fact is of medico-legal importance as showing that the amount of arsenic contained in in dead bodies diminishes through putrefaction.

THE MEASUREMENT OF THE GALVANIC CURRENT, WITH SOME REMARKS UPON ELECTRODES.[1]

BY PHILIP COOMBS KNAPP, A.M., M.D.,

When we give a drug there are two things of which we wish, in the first place, to have definite knowledge — the amount of the drug we are giving, and whether it will be absorbed or not. Therefore we prefer the graduate to the wineglass, and we do not inject our drugs into the bladder — in fact, when we wish to be sure of a drug's absorption, we inject it under the skin instead of giving it by the mouth. In the use of one powerful and even dangerous remedy, however, we too often act as if we were prescribing morphine or strychnine in a solution to be taken by the wineglassful, without even specifying whether a sherry glass or a claret glass should be used; and as if we were putting our remedy into some cavity, which absorbed very rapidly or not at all.

In many of the books and papers on nervous diseases, even in a book so recent and scientific as Eichhorst, the unit of measurement of the galvanic current is assumed to be the current obtained from one cell. The largest American work on therapeutics, too, scarcely mentions the subject of the measurement of the current. In point of fact, however, the amount of the current which passes through the patient's body — that is, the dose that he really gets — depends upon a number of different factors, the number of cells, the kind of cells, and the condition of the cells, the absorbing power of the patient, the size of the electrodes, and various other conditions. Most of those factors are recognized when spoken of, but they are so often neglected, and their influence is taken into such small account in the practical application of electricity, that I may perhaps be excused for calling attention to them once again.

There are two laws that govern the use of electricity, but as they are generally put into an algebraic formula, they are too apt to frighten those of us who have labored hard to forget our mathematics. These are the laws governing the intensity and the density of the current. The intensity is nothing more than the amount of electricity passing through the circuit; it increases with the electro-motive force; that is, with the amount of electricity generated in the battery, and it decreases with the resistance which it meets, just as a current of water through a pipe decreases as you shut the faucet: hence its formula was given as $I = \frac{E}{R}$. The density on the other hand, is equivalent to the pressure of water in the pipe; it increases with the amount of fluid passing through the pipe, and it decreases as you make the nozzle of the pipe larger; hence its formula is $D = \frac{1}{Q}$ (when Q equals the surface of the nozzle or of the electrode). Thus even an elementary knowledge of mathematics will show us that in our first formula $I = \frac{E}{R}$, by increasing or diminishing R, the resistance, we can get as marked results as by increasing or diminishing E, the amount of electricity generated in our battery, which depends on the number and strength of our cells; and also that our density, D, will vary with the size of electrode used, Q, as well as with the amount of our current, I.

Such being the case, it is evident that the number of cells employed forms but a part of the numerator of

[1] Read before the Suffolk District Society, Section of Clinical Medicine, Pathology, and Hygiene, June 7, 1887.

our first fraction; that is, that the electro-motive force, E, is in part dependent upon the number of cells, and in part upon their strength, and therefore, when the denominator of our fraction can and does vary, the numerator, or rather one factor in it, is valueless as a unit. Fortunately, we have a unit which covers both terms in the fraction, a unit which can become apparent at a glance, and which tells us, not the dose given, but the amount absorbed. That unit, as you are doubtless aware, is the milliampère, — an arbitrary unit, like the metre, but almost as exact and unvarying a unit as the metre. As the name implies, the milliampère is the thousandth part of an ampère, and an ampère is the amount of current obtained from an electro-motive force of one volt, (about equivalent to the electro-motive force of a gravity cell), passing through the resistance of one ohm, which is equal to the resistance of a column of mercury one millimetre square, and 1.05 metres high. Thus, by putting an "absolute" galvanometer into the circuit, which includes of course the patient's body, we can tell at a glance the number of milliampères used — a process easier, indeed, than reading off the number of cells, although it requires a little waiting for the needle to come to a stand-still.

To return to our first formula, $I = \frac{E}{R}$. In order to show how R, the resistance in the circuit, may vary, I performed a few simple experiments. In the ordinary application of electricity, of course, the main resistance is that of the body, which is so great as to render that of the wires and the cells of little account. Part of these experiments were performed upon myself, and part upon Dr. J. A. Jeffries. The battery was an old one of twenty-eight cells, the ordinary bichromate battery made by Thomas Hall, which had been cleaned and freshly filled, and gave a good current. A Hirschmann galvanometer was put in the circuit. A "large" electrode was put on the back of the neck as a positive pole, a "medium" electrode negative, was held against the palm of the hand.

Date, Dec. 1 and 2, 1886.

I. Skin dry, electrodes dry, covered with dry chamois. 28 cells. No current with either of us.

II. Skin dry, electrodes dry, bare metal. 12 cells. Self, 1 Ma. Same 28 cells. Self, 6 Ma. (?). This caused such painful burning that I could not wait for the needle to come to a stand-still.

III. Skin not wet. Chamois wet. 12 cells. Self, 7 Ma. Dr. Jeffries, 3 Ma.

IV. Skin thoroughly wet, the hand being washed with soap and held for some time in warm water. Electrodes covered with a thick layer of absorbent cotton over the chamois, and thoroughly wet. Firm pressure of electrodes. 12 cells. Self, 12 Ma. Dr. Jeffries, 5 Ma.

V. Same with kathode to flexor surface of wrist. Self, 13 Ma. Dr Jeffries, 9.5 Ma.

These experiments go to show the different resistance of the wet and dry skin, the different resistance shown by different persons, and also, though to a lesser degree, the different resistance of different parts of the body. This latter point has been brought out more fully in some experiments recently made by Dr. Prince.[2] Furthermore, repeated applications of electricity will reduce the resistance.

Just here I wish to make a little digression. The ordinary electrodes sold in the shops are covered with sponge. This holds water fairly well, and keeps the skin wet, but after frequent use, especially on Dispensary patients, it is about as nasty a thing as you would be able to find, nor is chamois skin much better. It is said that syphilis has been conveyed by such electrodes, and certainly our modern notions of cleanliness should lead us to discard them. Dr. G. B. Massey[3] some time ago recommended covering the electrode with absorbent cotton, and, after using it for nearly a year, I can recommend its use. It is cheap, clean, and easily applied, and as the following experiments will show, it does not materially impair conduction.

Date, Dec. 3, 1886.

VI. Two cells. Handle ends together. 6.5 Ma.

VII. Two "large" electrodes. Wet chamois. 5 Ma.

VIII. Same. Wet cotton over chamois, light contact. 3.5 Ma.

IX. Same. Firm contact. 4 Ma.

This variation, with a small electro-motive force, and low resistance, disappears with a larger force and higher resistances. To illustrate this, I put a "large" electrode on the back of the neck, and held a "medium" one to the palm. Descending current, skin thoroughly wet, ten cells.

X. Thick layer of cotton over chamois. 7 Ma.

XI. Chamois alone. 7 Ma.

Having thus shown the variability of the resistance, I wish to call attention to the fact that the electro-motive force is not indicated by the number of cells used, but that it varies with the form of cell. Dr. Watteville[4] states that the electro-motive force of the Daniel or gravity-cell is 1.08 volts; of the Leclanché cell, 1.5 volts; of the sulphate of mercury cell, 1.5 volts; of the chloride of silver cell, 1.03 volts; and the freshly-filled bichromate cell, 2 volts. Stein's "dry" cell has a force of 1.08 volts. The bichromate cell, which is probably the one most often used, as it is the cell of most of the portable batteries, is particularly objectionable as a unit of measure, for its strength is very variable. In the experiments made on the 2d of December, with a "large" electrode to the neck, and a "medium" one to the palm, it will be remembered that I got a current of 12 Ma on myself, and 5 Ma on Dr. Jeffries; with the "medium" electrode to the flexor surface of the wrist I got 13 and 9.5 Ma respectively. The battery was used more or less at the Dispensary for a fortnight, while the stationary battery was undergoing repairs. December 16, the experiments were repeated.

XII. "Large" anode to neck, "Medium" kathode to palm. Skin thoroughly wet as before. 12 cells. Self, 7 Ma. Dr. Jeffries, 4.5 Ma.

XIII. Same. Kathode to flexor surface of wrist. Self, 11 Ma. Dr. Jeffries, 7 Ma.

Some of the other cells, however, are more constant, and can indicate with greater accuracy, the electro-motive force. The gravity-cell, if kept in use, is fairly constant, and so are the Leclanche and chloride of silver cells, and Stein's "dry" cell, recently described,[5] is said to have lost only a tenth of a Ma, after being short-circuited continuously for twenty-four hours.

I have said enough, I think, to show that there are several factors to be taken into account in estimating the intensity of the galvanic current, and that the electro-motive force is not the measure of that intensity. I wish, now, to call attention to the fact that, in the practical application of galvanism, the density of the current is also an important point. That, as I have said, increases with the intensity, and diminishes with the size of the electrode, in the formula $D = \frac{I}{Q}$, just as the pressure of the stream of water increases

[4] P. Th. Stein. Ueber die Dosirung galvanischer Ströme in der Elektrotherapie. Berlin kl. Wochenschrift, 25. Jan. 1886.

with the "head" of water, and diminishes with the size of the outlet.

The instrument-makers put a couple of electrodes into their batteries, with discs an inch-and-a-half in diameter, and, when they are liberal, they add a wire-brush and some special form of bulb-electrode. In the general application of galvanism — I am not now speaking of the application to some internal organ, where an instrument of peculiar make is needed — it is as necessary to have electrodes of different sizes as it is to have knives of different sizes for amputations. The spinal cord and the deeper nerves cannot be reached by the current from a small electrode, at least, with a current strong enough to do any good; nor can a large electrode be used conveniently to test reactions, or to apply to the face.

In 1882, Erb, in his "Handbuch der Elektrotherapie," suggests a scale of sizes, which he had found convenient for general use. De Watteville soon after urged that they be accepted as the standard, and the Committee of the American Neurological Association have recently advocated their adoption. No instrument-maker, however, has offered them for sale, and no American work on electro-therapeutics that I know of speaks of them, so that I may be pardoned for describing them. I will add that I have found them to answer all requirements, after using them for nearly two years at the City Hospital and the Dispensary.

1 "Large" electrodes, 6 x 12 cm., for the cord, large joints, sciatic, and as an "indifferent" electrode.
2 "Medium," 5 x 5 cm. Face, neck, local application to nerves and muscles.
3 "Normal" 10 sq. cm. surface, 3.6 cm. diameter. To test nerve and muscle reactions, so as to have an unvarying denominator in the formula $D = \frac{I}{Q}$. This I have already described in detail.[7]
4 "Small." Ball, 2 cm. diameter. Smaller muscles and nerves. Eye.
5 "Smallest." Ball, 0.5 cm. diameter. Fine nerve branches and motor points.

Erb also uses a flexible electrode, 7 x 14 cm., for the head, and at times, in very short persons, a "very large" electrode, 8 x 16 cm. This last size will seldom be found necessary.

Every one knows that, even with a weak current, if we use a wire-brush, where the fine points of the wire conduct the electricity into the skin, we cause considerable pain. A current of the same intensity, passing into the body through a larger electrode, that is, a current of lesser density, will cause no pain at all. In the same way, a current applied through a "large" electrode will be easily borne, when, if we give the same current through our "smallest" electrode, we will get great pain. Hence, if we wish to use strong currents, we must use large electrodes, otherwise we will get pain, and even blisters, which are undesirable. Furthermore, it will be found that the intensity of the current varies with the size of the electrode — that a small electrode increases the resistance.

Dec. 2, 1886.

XIV. To show the painfulness of the small electrode I put the "large" anode on the back of the neck, and a "large" kathode to the palm. Skin well wet, cotton to electrodes, 28 cells. Self, 23 Ma. Dr. Jeffries, 21 Ma.

We both noticed a marked and unpleasant sensation in the neck and throat, a metallic taste, etc.

XV. Same "large" anode to neck, "smallest" kathode to ball of thumb. Self, 12 Ma. Dr. Jeffries, 10 Ma.

This caused no general sensations, but an acute, burning pain at the kathode, so that we feared a blister, and took off the electrode as soon as the needle came to a standstill.

Dec. 3, 1886.

XVI. "Large" electrodes as before to neck and palm. 16 cells. Self, 12 Ma. Distinct, but not unpleasant general sensations.

XVII. Same with "smallest" kathode to ball of thumb. Self, 3 Ma. Slight local sensation during passage of current, burning after taking off electrodes. No general sensation.

This led me to investigate more carefully the effect of the size of the electrodes.

Dec. 4, 1886.

XVIII. "Large" anode to back of neck, kathode to palm. 16 cells. "Large" kathode, 10.5 Ma.; "Medium" kathode, 7.5 Ma.; "Normal" kathode, 5 Ma.; "Small" kathode, 4.5; "smallest" kathode, 2 Ma.

These results agree in the main with those reported by Erb[8] and Prince[9]. Erb states, also, that the area of the epidermis modifies the results, as well as its thickness. Fischkau, however, in a recent monograph,[10] states that the resistance is due to the wetness of the skin, the pressure of the electrode, the duration of the passage of the current, the intensity of the E. M. F., temperature, point of application, and certain internal conditions of the organism. The size of the electrodes, and the space between them, make no difference in resistance. Such a statement, in view of the facts shown by Erb, seems untenable.

We see, then, that we must consider the density of the current we are using, as well as its intensity, if we wish to use strong currents and avoid pain, and the density depends, in part, upon the size of our electrodes. There is another point, however, in regard to this density, to which I have referred, which is of still greater importance. With electrodes of equal size, the density is alike at each electrode; with electrodes of unequal size, the density is greater at the smaller electrode, as Erb shows in his figures; and, in both cases, the density is greater near the electrodes. Therefore Erb says that, if we wish to reach some special point near the surface, we should place a small electrode over it, and a large electrode on some indifferent part, thus getting the maximum density at the point desired. To reach a large part near the surface, we put two good sized electrodes near together, while, if we wish to affect deep-seated parts, such as the cord, we must use large electrodes, and place them far apart. Erb's rule in applying galvanism to the cord is "large electrodes, and far apart." In this way, too, by diminishing the local pain and burning, we can use strong currents, which are sometimes desirable.

I have given only a rough and hasty account of some of the factors which must be considered in the practical use of galvanism, with a few simple experiments to show the need of considering these fundamental rules. Accurate dosing is as important in electro-therapeutics as it is in internal medication, although, in both cases, we must vary our dose to suit our patient. In electro-diagnosis, moreover, this accuracy becomes still more necessary, and, without some trustworthy measure, our judgments must be merely approximate, and often fallacious.

CASCARA SAGRADA, AND ITS USE IN THE TREATMENT OF CONSTIPATION.[1]

BY JOHN W. FARLOW, M.D.

CASCARA SAGRADA is the bark of the rhamnus purshiana, a shrub fifteen to twenty feet high, belonging to the Buckthorn family, which is found only on the Pacific coast of the United States, from Cape Mendocino north to British America, though it is not common in Washington Territory. It was first botanically described, under the name, however, of rhamnus alnifolia, by Frederic Pursh, a German, in 1814. De Caudolle, in 1825, first recognized that rhamnus alnifolia of Pursh was not the same as rhamnus alnifolia of L'Heritier, and he described the form which Pursh called alnifolia as rhamnus purshiana, and all subsequent writers follow De Caudolle.

Other members of the buckthorn family of medicinal value are rhamnus frangula, black alder, which grows extensively in Europe and rhamnus cathartica, common buckthorn, whose habitat is farther north than the preceding. The bark of both of these is used as a cathartic, which has caused them to be confounded with rhamnus purshiana. For instance, Dr. Douglas Lithgow,[2] in an article on cascara sagrada says, it was well known to early writers and was mentioned by European botanists in the thirteenth century. As this was before Columbus discovered the Eastern Coast of America, it is fair to infer that what was said by those Europeans about the botany of the West Coast was of very little value.

Cascara seems to have been used for some time, and it is probable that its resemblance to the European varieties led the early traveller and missionaries to use it as they had used rhamnus cathartica, and the natives, seeing it used in that way, were ready to adopt it as a cathartic.

It was first introduced to the medical world by Dr. Bundy, an electric physician of Calusa, California, who chanced to select this plant among many others having a local reputation among the natives for experiment. He, however, was ignorant of its botanical name and called it by the Spanish name known to the natives. The words cascara sagrada, or sacred bark, seem to have reference, not to its medicinal virtues, but to the resemblance of the wood to the chittem or shittim wood mentioned in the Bible, from which it is supposed the ark of the tabernacle was built; in fact, cascara is also called chittem wood in California.

The bark contains a brown resin, a red resin, a light yellow resin, a crystallizable body, tannic, malic and oxalic acids, a fat oil, a volatile oil, wax and starch in abundance. The exact nature and value of these various constituents has not yet been determined, nor has their relation with the constituents of the other rhamnaceæ.

The preparations of the drug used in medicine are the solid extract, powdered solid extract, fluid extract, elixir and the cascara cordial of Parke, Davis & Co. Of the dose and modes of administration I shall speak later.

In choosing a remedy for constipation we should select one that will do no harm and whose after-effect is not to increase the trouble for which it was given. It should not cause griping or any uncomfortable feeling, even if this can be overcome by the addition of opium, belladonna or other narcotic. It is also desirable that the remedy should not have to be given in increased doses, but the contrary, and the form of administration should be such that the dose can be small and can be carefully regulated for the individual case. Dr. Jacob Bigelow used to say that "a great deal of the success of a physician depended on his understanding the constitution of his patient; in other words, how large a dose of cathartic medicine it took to move his bowels." It is not generally expected that the remedy should have very much influence on the appetite and digestion, other than as a result of emptying the bowel, but, if the medicine is of itself an aid to digestion, so much the better.

Let us look at cascara and see if it fulfils any or all of these indications. I have used it for two or three years and have notes of over two hundred cases which I have followed long enough to know the result. The cases in which I have ordered it and where the patients have not returned I have left out of consideration entirely The cases have generally been those of more or less chronic constipation, and often associated with uterine or pelvic trouble as well as with disease of the rectum and anus. I have also used it in pregnancy and after labor. I have, in most instances, prescribed the fluid extract.

I do not propose to consider the various methods of treating constipation, regular habits of defæcation, exercise, diet, etc. I take it for granted that all such measures are to be tried before any medicine is given.

Is cascara an efficient laxative? In every case in which I have used it and have the records it has not failed to cause one or more dejections for a certain time. Several of the cases have been of very long standing, and had tried all imaginable drugs and combinations of drugs in vain. Mrs. S., for instance, forty-five years of age, had recently been in one of the Boston hospitals for six weeks for constipation. She had taken everything but cascara to no purpose. At the end of ten days, after taking cascara in gradually decreasing doses, her bowels became regular and soon she was able to have a daily stool without any medicine. Mrs. H., fifty-six years old, had always been constipated and had exhausted the usual remedies. After using cascara, at first in rather large doses and then diminishing, at the end of three weeks her bowels moved once a day by simply taking fruit in the morning.

Does it cause griping or any uncomfortable feeling? Very seldom, indeed, if it is correctly used and the dose rightly apportioned to the particular person. I have seen two or three cases where the patients complained of some griping, but on investigation I found that more than enough had been taken, or that, instead of diminishing the dose when it had begun to act freely, the same dose had been continued. Cases are reported by others in which griping occurred, but, according to my experience, this must be uncommon, and possibly some of these were due to too large a dose at one time. Some persons seem to be very easily affected by it, and this idiosyncrasy should be borne in mind in determining the dose.

In the administration of drugs which cause griping it is usual to combine with them something to stop the griping; in other words, to allow the drug still to irritate the intestine, but to take away the reflex contraction of the intestine causing the pain, or else to

[1] Read before the Suffolk District Medical Society, Section of Clinical Medicine, Pathology and Hygiene, June 7, 1887.

[2] Brit. Med. Jour., ii, 1883, p. 68.

blunt or remove the perception of the pain. This I hold to be a mistake, as the irritation of the bowel is injurious in many cases and the pain should be the signal that such is the case. The irritation is just as bad for the bowel, even when the pain is not allowed to manifest itself.

Most laxatives have a secondary, constipating effect, necessitating an increase of the dose or a change to some other drug. This is not the case with cascara, as the usual method of giving it is to diminish the dose after a few days.

What is its effect on the digestive system? Its use does not impair the appetite or digestion, but, on the contrary, increases the appetite and promotes digestion. On the intestine it seems to have a tonic action and is particularly adapted to conditions of atony of the stomach and bowels. The stools caused by it are soft, or semi-solid and not watery, unless too large a dose has been taken.

I have also found it of good service in the treatment of hæmorrhoids, by relieving the congestion and causing a soft, painless stool. It seems to have a beneficial effect apart from and in addition to its laxative effect in these cases as well as in some cases of fissure. The following is a good illustration: Mrs. F., aged thirty-one, mother of five children, had always suffered from constipation and piles, particularly after labor, and had never found anything to relieve her. I attended her in a difficult labor with breech presentation. She had very marked hæmorrhoids, which caused her so much trouble after labor that she could not sit on a chair, and every movement was painful. She obtained entire relief by using cascara in twenty-drop doses of the fluid extract, four times a day for three days.

The importance and at the same time the difficulty of regulating the bowels in gynecological cases is well recognized, but my experience with cascara in such cases leads me to give it the highest rank. I have notes of its very satisfactory use in several cases of endometritis, large uterine fibroids, flexions and versions, large and tender ovaries, one case of retroflexed pregnant uterus requiring forcible reposition, and a number where there were tender places and bands in Douglas's pouch, readily felt per rectum.

According to my experience, the cases for which cascara is particularly adapted are the chronic cases and especially those with weak and atonic digestive organs. For such patients it is far superior to rhubarb, senna, aloes, licorice powder and the usual laxatives, either alone or in their various combinations. For acute cases its peculiar qualities are not so much required, although it generally acts promptly, surely, and without secondary constipating effect.

I have generally used the fluid extract, for several reasons. It is an active and reliable preparation, the dose is small and can be easily regulated by increasing or diminishing the number of drops taken at a time. The taste is bitter, to which some object, while others find it not unpleasant. To the latter it can be given in water or with equal parts of glycerine in water. Most of the substances supposed to disguise the taste only add a sweet to a bitter and the combination is to many worse than either alone. I should say that the fluid extract of licorice, is perhaps, as good an excipient as any. Cascara cordial has an agreeable taste, and is preferred by many. The dose is, of course, larger and is not so easily regulated as the fluid extract. The solid extract is given in pill form, and consequently can be taken without the bitter being tasted. If, however, the dose in each pill proves too large, a new lot with a smaller dose has to be procured, which is a disadvantage as compared with the fluid extract.

The dose of the cordial is about a teaspoonful morning and night, or oftener. The solid extract is given in doses of two grains or less, three times a day. The dose of the fluid extract is from five to twenty-five drops, and I generally order it to be taken as follows: If the case is of long standing and one in which many drugs have been tried, I direct ten or fifteen drops to be taken in water before each meal and at night. If that does not cause one soft dejection a day, in two or three days I increase the dose to twenty-five drops four times a day, and tell the patient to take sufficient to have one dejection a day. Then in a few days, at any rate, or immediately, if he has more than one stool, a day, he is to diminish the dose from thirty to twenty-five, twenty or fifteen drops, but always enough for one soft stool a day. It is better to diminish the quantity taken at a time than to lessen the number of times. It will be found that five or ten drops at night often prove sufficient. It is well to omit the medicine from time to time and it can frequently be dispensed with altogether. If necessary to resume it, let only the amount be taken that was previously found to be sufficient.

REPORT ON PROGRESS IN SURGERY.[1]

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

FRACTURE OF PATELLA.

Von Bergmann reports[20] a case of transverse fracture of the right patella, treated in the following manner: A sailor, aged twenty-two, sustained a fracture of the right femur, and a transverse fracture of the right patella. Result: union of femur, with seven centimeters shortening (subsequently relieved by osteotomy); non-union of patella. On failure to approximate the fragments during an attempt to suture them together, Von Bergmann made a curved incision around the tuberositas tibiæ, and chiselled obliquely through the bone, from below, anteriorly upwards and backwards into the joint. He then, by pushing up the fragment, united the patella. Bony union subsequently united the tibiæ fragment. The patient, when shown about sixteen months after the operation, is reported as walking well, but the motion of the right knee is quite limited.

TAUBER'S AMPUTATION AT THE ANKLE-JOINT.

Professor Tauber, of St. Petersburg,[21] has demonstrated his operation, which is a modification of Pirogoff's. "He begins an incision at the attachment of the tendo Achillis, and carries the knife forward, below the external malleolus, to the Chopart's line, and then across to the dorsum of the foot. On having reached the middle line on the plantar surface, the knife is carried backward to the heel, and then upward to the starting point.

"In this first stage of the operation, Dr. Tauber cuts the skin and other soft tissues to the bone. In the

[1] Concluded from page 383.

[20] Versammlung deutscher Naturforscher und Aertze zu Berlin. Berl. Klin. Wochschr., October 4, 1886.

[21] Ann. of Surg., January, 1887.

second stage he opens the ankle joint in the usual manner, that is, he cuts the ligaments in the following order, lig. fib. tali. post., lig. fib. calcan. and lig. ant.; then interosseus ligament, and, at the last, the deltoid ligament. In the third stage, Dr. Tauber dissects out the astragalus, and cuts off the foot in Chopart's line. While an assistant firmly holds the os calcis by forceps. Professor Tauber saws off the external half of the bone, in the line corresponding to the one first made in the skin. Thus the flap of the heel contains a thick, almost square part of the os calcis, and the posterior tibial artery uninjured. In the fourth stage, Professor Tauber saws off the malleoli, ligatures the arteries, severs and adjusts the two surfaces of the bones to each other, which is easily done without any extension on the tendo Achillis. Lastly, the wound is united with sutures."

DUPUYTREN'S CONTRACTION OF THE PLANTAR FASCIA.

Madelung [22] has collected six cases of Dupuytren's contraction, where an analogous condition of the plantar fascia was also present. The sole of the foot presented the appearance of a nodular callus, caused by the contraction of the plantar fascia, which had become intimately connected with the skin. In regard to ætiology, Madelung rejects the theories of mechanical irritation, gouty diathesis, or neuritis, and considers that a central origin is more probable.

MALIGNANT ANTHRAX.

Dr. A. Bois [23] reports very carefully a case of this frightful disease, and believes that two facts are evident from his case: (1) that the thermo-cautery has an incontestible power in stopping anthrax, even when malignant, provided that it be used beyond the limits of the disease; (2) that an anthrax may, for some days, maintain a benign course, increasing insidiously, and causing a false security. It may then take on suddenly the serious character of a disease beyond our resources, in consequence of the septicæmia which it engenders.

In corroboration of the above, Guiseppe Moggi [24] reports two cases in which the galvano-cautery treatment was used, supplemented by two per cent. carbolic injections, with one recovery and one death. In a third case, the carbolic injections and quinia were used at first, but later, when the disease was apparently uncontrolled, the galvano-cautery was employed, with an immediate improvement of the symptoms. The patient eventually recovered. Guiseppe adds that a large number of cases have been treated in this manner, with good result.

ARSENICAL TREATMENT OF MALIGNANT TUMORS.

F. Koebel [25] has reported the results attained at Brun's Klinik, Tubingen, by this method of treatment. His conclusions are that a trial of the internal administration of arsenic in all inoperable cases of malignant lymphoma, and in certain ones of general sarcomatosis, is to be recommended; that, although many cases are not cured, still some brilliant results have been obtained. In epithelial carcinoma and inoperable cases of mammary disease, local injections of arsenic were wholly valueless. With lympho-sarcomata, the results were negative. Of fifty-nine cases of malignant lymphomata, seventeen entirely recovered. In five, the disease recurred in from two to eight months. In fourteen cases, a partial recovery was obtained. Of the twenty-eight cases remaining unrelieved, with some, the time allowed for observation was too short. In the seventeen successful cases, the time elapsing to complete cure varied from one to six months. The treatment consisted in the exhibition of liq. potass. arsenitis internally, in gradually increasing doses, to a maximum of gtt. 40 to 45 daily, in parenchymatous injections, gradually increasing from 0.4 to 0.5 ctgms. *per diem*. The treatment should be continued for, at least, two months before being abandoned as unsuccessful.

GRAFTS OF FROG'S SKIN.

Morales Perez [26] has transplanted three quadrangular grafts two centimetres wide by three centimetres long, to a burn of the hand. After five days these grafts were found adherent, except two small bits. Two additional grafts were made in other points which adhered. After some days the epidermis and the blackish green pigment of the graft dried up, and left a thin white cicatrix, which became a satisfactory elastic covering to the grafted area.

TREATMENT OF WOUNDS OF VEINS BY LATERAL CLAMP.

The usual method of dealing with wounds of large venous trunks are double ligation and section of the wounded vessel, lateral ligation or occlusion by clamps. Complete ligation causes greater or less serious venous obstruction. Lateral ligation, on this account, was reintroduced by Braun, in 1882, who demonstrated that this method when successful, preserved the lumen of the vessel. In the Agusta Hospital (Berlin), wounds of the jugular axillary and femoral veins have been successfully treated by this method. H. Schmid, of the above hospital, has recently investigated this subject.[27] By a series of experiments he concludes (1) That in a perfectly aseptic wound a clamp can be removed from a wounded vein at the end of twenty-four hours, but of course with great care and without any tearing. That it never should be left *in situ* longer than forty-eight hours. That the lumen of the vein remains patent. That a secure cicatricial closure of a vein wound is not obtainable before fourteen days after removal of the clamp. That there is no especial difference between applying the instrument in a longitudinal or transverse direction.

In what manner the union of the wound was accomplished was not ascertained. Koeberle or Pean forceps may be used to close the wounded vessel. Schmid reports also seven cases, two of subclavian venous wounds, one axillary, three jugularis communis, and one femoral. The clamps remained in place about twenty-one hours under an antiseptic dressing, and were then cautiously removed. No secondary hæmorrhage or disturbance of circulation followed.

THE TREATMENT OF VARICOSE VEINS.

The excision of varicose veins has been tried with a fair measure of success; Le Brun [28] reports twenty-

one operations without an accident. Fry[29] reports six cases with complete success.

Stevenson[30] reports eight cases treated by the injection of pure carbolic acid, after Watson Cheyne, and Weber[31] reports a varicosity of the saphenous vein successfully treated by the injection of pure carbolic acid.

This method of Cheyne's is undoubtedly quite safe and gives fairly good results. The procedure is as follows: An Esmarch tube should be secured around the thigh sufficiently tight to stop the venous circulation, then in about a minute it should be made tight enough to shut off all the circulation. Injections of one minim of pure carbolic acid should be made into the veins at about an inch-and-a-half apart, beginning at the upper end of the vein. These punctures should be closed antiseptically and the elastic tourniquet should be removed cautiously, after the lapse of fifteen minutes. Patient should be confined in bed for a week.

LIGATURE OF THE POPLITEAL ARTERY FOR ELEPHANTIASIS OF THE LEG.

Three cases, with favorable results, are reported by E. Dignino (Caraccas):[32] (1) A middle-aged man, with his left leg and foot enormously enlarged by elephantiasis. The popliteal artery of that side was ligatured with considerable difficulty, owing to the alteration of the tissues of the limb by the disease.

The wound healed in about fifteen days, and from that time until his discharge, two months later, a marked and continual amelioration of the elephantiasis was observed. (2) Patient male, aged forty-two, with elephantiasis of both legs. Ligation of the left popliteal artery resulted so satisfactorily, that the patient urged similar treatment of the other limb. (3) This was done successfully. The author, from the above cases, is inclined to advise ligation before amputation, which usually produces but temporary relief, the disease soon appearing in some other region.

HÆMORRHAGE INTO ABSCESS-CAVITIES FROM LARGE VESSELS.

Güterbock's investigations[33] have led him to the conclusion that hæmorrhage from the larger vessel-trunks in abscess-cavities, aside from the commonly known inflammatory destruction of the vessel-wall, also results from a circumscribed thinning, extending from without inwards, as has been demonstrated in a case of Miller's of the aorta, and of Güterbock's, where the profunda femoris was affected. With the exception of the ulcerated spot, the vessel-wall was normal. The cause is supposed to exist in the irritating action of decomposed pus in an abscess-cavity. The most exposed to this action are the vessels situated at the bottom of such a cavity, and especially at the point of bifurcation of a main trunk or a large branch.

INDICATIONS FOR THE TREATMENT OF GUN-SHOT INJURIES OF JOINTS BY RESECTIONS.

The present ideas in regard to the treatment of gun-shot wounds of joints by primary or secondary resection is discussed in an elaborate article by Schuchardt.[34] After presenting a detailed comparison of the recorded statistics, Schuchardt gives the following conclusions:

(1) Joint-resections for gun-shot injuries performed before the introduction of antiseptic surgery yielded very unsatisfactory results, both in rate of mortality and functional results.

(2) That, formerly, primary resection gave superior results, both in regard to recovery, and to the function of limb.

(3) That the bad results caused the adoption of an expectant or strictly conservative plan of treatment by the most experienced army surgeons.

(4) Since the introduction of the antiseptic treatment of open wounds, the indications for resection have become reduced, and the results from expectant treatment considerably improved.

(5) That even when operative interference is indicated, total resection is only required where both articular surfaces are extensively involved. In most cases, simple arthrotomy, with any osseous fragments, a thorough irrigation and drainage followed the removal of the bullet.

(6) Free exposure of the interior of the wound is indicated only in dirty wounds or extensive injuries of soft parts. With a small wound and favorable external conditions, the presence of a bullet or other foreign body, a free primary incision into the articular cavity is not indicated, for, by simple aseptic occlusion, most cases recover without serious impairment of function.

(7) Secondary resection is indicated where expectant treatment has failed, and an abnormal appearance of the wound, or interruption of the healing process, are indications for prompt operative interference.

(8) The duration of treatment in aseptic cases is slightly shorter after primary than after secondary resection, but not enough to justify its preference to the conservative or expectant plan on the battle-field.

(9) Although, theoretically, the dangers of a fatal result are less after a primary than a secondary operation, this comparison is not fair, since the secondary operation is performed only after the expectant treatment has failed, and, for each secondary resection, many others recover after antiseptic occlusion.

(10) Functional results depend on the amount of bone removed, and the kind of after-treatment.

(11) In the knee or ankle, ankylosis or an amputation-stump is preferable to a movable joint.

(12) Transportation is more unfavorable to a patient after resection than after the expectant plan. For this reason, and also since, on account of the large number of wounded requiring attention after a battle, an aseptic subperiosteal resection is attended with great difficulty. Such operations are to be avoided, if possible, on the field.

TEMPERATURE IN CASES OF SUBCUTANEOUS FRACTURES.

E. Mueller[35] has investigated three hundred and fifty-nine cases of subcutaneous fracture, with reference to variations of bodily temperature. Contrary to the former idea that simple fractures were rarely followed by elevation of temperature, Mueller found

that this occurred in eighty-five per cent of the above cases. In his own cases the change ranged from 38° to 40° C. The maximum rise occurred on the first or second evening following the accident. In some cases the fever continued thirteen days. Transportation did not appear to increase the temperature. As a rule, the temperature increased in direct proportion to the extravasation of blood, but this was not an invariable rule.

CHANGES IN NERVES AND SPINAL CORD, SECONDARY TO AMPUTATIONS.

F. Krause,[35] reports the following results of an examination of nine cases of amputation at from ten days to six years after operation. He found an atrophy of the sensory fibres which extended to the spinal ganglion. A diminution in size of the posterior columns (in the lumbar and dorsal cords after amputation of the lower extremity, in the cervical cord after amputation of the upper). The nerve fibres remained intact. There was an atrophy of the gray matter of the posterior horn especially marked in the lumbar region, and the ganglion cells in the posterior lateral portion of the anterior horn were diminished in the proportion of one to three.

ÆTIOLOGY OF COLD ABSCESSES. SUPPURATION OF GLANDS, MUSCLES, BONES, AND TUBERCULOUS JOINTS.

Dr. C. Garrè, of Basle,[37] has written an interesting article on this subject, in which he details his experiments and researches for the purpose of ascertaining what influence as an ætiological factor is exerted by micro-organisms. He regards the ætiology of acute abscess as practically established, and summarizes the present theory as follows: That acute suppuration is caused by the penetration of pyogenic microbes into the tissues. That neither chemical nor physical irritation can cause suppuration, if micro-organisms are carefully excluded.

That inflammatory exudation becomes through the vital action of germs (Spaltpilze) changed to pus. In regard to so-called "cold abscess" less work has been done and less positive results attained. He concludes, however, that micro-organisms also play an important part in the ætiology of the latter. The chronic form depending on the presence of the bacillus tuberculosis, the acute outbreaks resembling acute abscesses upon the staphylo — or streptococcus. He harmonizes the facts that inoculations from cold abscesses result in general tuberculosis where the microscope and gelatine culture fail to demonstrate the presence of bacilli by assuming that the results are due to the presence of spores whose minute size and great resistance to staining fluids prevents their demonstration by these means. That these must be the infecting agents, since Koch has disproved the chemical theory, and that of non-organized ferments. Garrè states that phlegmonous pus can be distinguished from that due to tuberculous processes.

Phlegmonous.	Tubercular.
Thick and yellow.	Thin, serous-like.
Formed by active transudation of migrating white corpuscles.	Formed by serous transudation containing necrotic detritus of tissues disintegrated by cheesy degeneration.
Microscopically the pus cells are abundant and well formed, have sharp contour, distinct nuclei, and stain clearly.	Microscopically the cells are generally fatty, degenerated and in fragments. Stain indistinctly.

[35] Berl. Klin. Wochenschr., October 4, 1886, p. 685.
[37] Deutsche. Med. Wochenschr., xii, No. 34.

He also states that the failure to cultivate the spores is because living organisms only supply the necessary conditions to develop them into bacilli.

THE ACID CALCIUM PHOSPHATE TREATMENT OF TUBERCULOSIS.

In imitation of the process observed in the healing of lung cavities, Kolischer[38] has injected tubercular joints with solutions of acid calcium phosphate.[39] For hypodermic injections:

℞ Calci. phosphoric neutral . . . . . 5 parts.
Aquæ distill. . . . . 50 parts.
Add phosphoric acid until a perfect solution results; filter, add
Acid. phosphor. dil. . . . . 6-10 parts.
Aq. dist. . . . . q. s. ad. 100 parts.

For an escharotic effect upon tuberculous ulcers and indolent granulations, the following is used:

℞ Calci. phosphoric neutral . . . . . 50 parts.
Aq. dist. . . . . 500 parts.
Add phosphoric acid until a perfect solution is obtained; filter, add
Acid. phosphoric. dil. . . . . 60 parts.
Aq. destillat. . . . . q. s. ad. 1000 parts.

Gauze may be soaked in this fluid, and used in dressing tuberculous fistulæ and pockets.

Previous to injection the surface of the diseased part is disinfected. The injection is made with a platinum needle introduced deeply into the tissues; if great pain results, cocaine may be added to the solution. The contents of a Pravaz's syringe may be given at one injection after being sterilized. Kolischer considers the method of especial value in children; in many cases speedy cures result, while others recover after prolonged treatment. Rare cases occur where there is no effect.

Two cases of acute tuberculosis of the elbow-joint in children were exhibited, where a cure had given a normal contour to the joint and good motion resulted.

Five hundred cases have been treated by this method, and Fronshauer and Albert believe it is destined to improve markedly the results obtained in localized tuberculosis.

THE USE OF DRILLS AND NAILS AFTER RESECTION.

J. A. Wyeth[40] considered that steel drills for fixation of the knee-joint after resection, were better than nails, since there was less danger of crushing the bone. Gerster had found that the dry-goods box nail answered the purpose, and advised placing the finger between the bones and the popliteal vessels to guard against accident, also to prevent any lateral displacement of the bones during the operation.

Clinical Memorandum.

A CASE OF AGORAPHOBIA.[1]

BY ALBERT N. BLODGETT, M.D., OF BOSTON.

The patient is a man, forty years of age, married, in whose family history there is no known peculiarity or hereditary predisposition. At the age of ten years, while crossing the Atlantic Ocean, from some cause unknown to the patient, he became suddenly and totally blind. From that time he has never recovered the power of vision, and the eyes have undergone a process of atrophy, so that the bulbs are little, if any, more than one-half the size of the natural organs. The patient was never a particularly strong person, but has not had more than the average amount of sickness, nor have the illnesses from which he has suffered been in any way extraordinary. Since the loss of sight, the patient has noticed a peculiar sensation, unknown before, which came only at rare intervals at first, but has gradually increased, both in frequency and in the degree of severity, until it now affects him continually, and is a cause of constant distress to him, as well as of anxiety to those around him. This affection consists of a sensation of giddiness, or perhaps, more properly, of vertigo, for it is usually accompanied by a feeling of nausea, which was, at first, usually noticed more particularly after unusual exertion, or in conditions of great exhaustion, but which have since been so constant as to leave him hardly any period of freedom.

The vertigo is accompanied by a peculiar state of mental distress, which the patient describes as a most torturing feeling of anxiety, which hangs over him all the time, and is steadily increasing. He is afraid to go about; he is terrified at the thought of crossing the street, or at the idea of walking through a public square or place. He is thrown into a state of fear by the attempt to cross a park, even when not alone, and is made so wretched by the same sensation in the horse-cars, that he seldom comes into town, though the distance from his home to the city is but trifling.

The giddiness is often accompanied by a sensation of fulness in the region of the stomach, and the patient frequently belches large quantities of gas during or after the severer attacks of vertigo. He thinks that his stomach is "sensitive," and does not take cold drinks, for fear of "chilling the stomach." Does not partake largely of either tea or coffee. His digestion is said to be good, natural rest is obtained, though the actual amount of sleep is seldom more than six or seven hours, and he wakes refreshed and invigorated. He can never tell, by any symptom, when the exacerbations are coming on, but is sure that the malady is gradually becoming more and more constant, and that it is also more severe than formerly. He now seldom goes out on any pretence, on account of the fear or sense of oppression which the sensation of infinite vastness around him causes him to experience. He has no ringing in the ears, and suffers no pain, other than a sense of dull aching in the frontal region, and the discomfort in the region of the stomach. He has no vomiting or other gastric disturbance, and no signs of any organic disease. Pulse 72, temperature normal.

The patient's skin is of a tawny hue, reminding one of the peculiar color of the surface in advanced marasmus, or in cases of extensive malignant disease, and resembles somewhat the dusky tint observed in Graves's disease. The other features of these maladies are, however, totally wanting in our patient, and the coloration of the skin may be only an accidental or congenital coincidence. The patient is thin, bony, and has the appearance of constant expectation, or, one might almost say, apprehension of impending danger. There is no indication of any mental or moral impairment in the patient. He is a man of fine sensibilities and of acute understanding, and is fully up to the standard of ordinary men.

This condition does not seem to be due to the perversion of any of the special senses, nor is it peculiar to persons who are deprived of any of the special senses. During a considerable acquaintance with the blind, and some experience in the treatment of disease in these unfortunate persons, I have not observed in them the indications of the condition I have here described.

The condition in this patient seems to be a psychosis — a functional disturbance of the intellectual faculties — and is similar, in some degree, to the sensation of unsteadiness which sometimes precedes the giddiness associated with threatened seasickness. From this similarity, it has seemed to me that the disease might be connected with some derangement of the sympathetic nervous system, or with some obscure condition of disturbed function of the semi-circular canals of the internal ear, although I have not been able to establish such a connection in this case. It is well known that slight interference with the sympathetic nervous system may bring on symptoms resembling those of aural vertigo, and that the passage of the galvanic current through the cervical sympathetic will occasion, in a healthy person, a train of symptoms resembling to some extent those noticed in this patient. There is no appearance of impairment of any of the cerebral functions or faculties, nor is there, apparently, any disturbance of motion or of sensation. The special senses, with the exception of that of sight, seem to be normal, unless the increased acuteness of

[1] Read before the Suffolk District Medical Society, Section for Clinical Medicine, Pathology, and Hygiene, June 7, 1887.

the remaining senses, observed after the abolition or serious impairment of one of them, be reckoned a pathological condition.

Dr. Ferdinand Bottey, in the Societie Medico-Pratique, made an interesting communication upon the subject of "Claustrophobia or Clitrophobia." This affection is also a psychosis, but of exactly the opposite character from that recorded in this paper, and manifests itself in uncontrollable anxiety and terror on the part of the patient, when in any closed room, or in any confined space. In Bottey's case, the patient, who is now forty-three years old, had suffered for twenty years from articular rheumatism, for ten years from chorea, and later, from typhus.

The patient has no neurotic ancestry. After a public assembly, ten years ago, there was a disturbance in the streets, in which the patient was nearly crushed by the crowd. He suddenly became much distressed, which was followed by a condition of absolute helplessness. He was greatly excited, trembled in his entire body, the surface of the skin was covered with perspiration, and the face was deathly pale. He was certain that he could never live to get out of the crowd, or would surely be injured. From this time, the patient has been subject to frequent repetitions of this condition, in which his sufferings are most intense. In travelling by rail, his tortures are increased by the entrance of each new passenger into the conveyance in which he is seated. The situation at length usually becomes so painful to him, that he would much prefer to die than to continue the journey. If he chances to be in an omnibus, he is somewhat more comfortable, as he can always get out of it, and thus gain space. He once was driven to that point of desperation on a small steamer, that he tried to jump overboard into Lake Geneva, and was restrained only with much trouble. He will not trust himself to sleep in a hotel. In the theatre, he always selects a seat in some corner near the exit. The patient is active in political affairs, and his peculiarity was the cause of much merriment on one occasion, because he insisted on having the platform for public speaking located near the outer door, at the rear of the auditorium, without being able to give any plausible reason therefor. Otherwise, the condition of the patient is normal in all respects. He is of very cheerful temperament, and no one outside of the circle of his intimate friends is aware of his peculiarity. In etiological directions, it is of interest to know that the mother of the patient suffered from stone, his father was rheumatic, one grandfather was gouty, and the patient is also rheumatic. Thus far, it would appear that the arthritic diathesis may stand in some causative relation to this psychosis.

The condition here imperfectly described seems to consist of a pure neurosis of obscure and variable character, similar to some of the other forms of psychical disturbance, and is sometimes seen in relation to various chronic diseases, particularly syphilis. In this form of the affection, the mind of the patient is filled with an unreasoning and indescribable fear of the disease, even although he may know that no symptom of the malady has ever existed in his person.

— The Emperor William has sent a sum of ten thousand marks to be distributed among the necessitous people in the cholera stricken districts of Messina.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY.
SUFFOLK DISTRICT.
SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

JUNE 7, 1887. By the courtesy of the Massachusetts Institute of Technology, the Section was convened in Huntington Hall.

The meeting was called to order, at eight o'clock, by the Secretary, who announced that DR. KNIGHT, the Chairman, had been suddenly called out of the State, and would not be able to attend the meeting. On motion of DR. C. P. PUTNAM, DR. S. W. LANGMAID was chosen Chairman, *pro tem.*

The reading of the records of the last meeting was omitted.

DR. C. P. PUTNAM, in behalf of the Committee on Physical Education of School-children, presented a report of progress, and offered a written recommendation for further action upon this subject by the State Society, which was unanimously carried.

The recommendation is as follows:

"*Voted*, That the Section of Clinical Medicine, Pathology, and Hygiene recommend to the Massachusetts Medical Society that it authorize the President to appoint a committee to investigate the methods of physical culture now employed, to consider their relative value, and to report what they regard as the best plan to be adopted; and also, that such report be laid before the Commissioners of Education."

DR. W. J. FARLOW read an interesting paper on

CASCARA SAGRADA, AND ITS USE IN CONSTIPATION.[1]

DR. J. J. MINOT stated that he had used this remedy to a considerable extent in the treatment of constipation, and always with the most satisfactory results. The remedy, in his hands, has always proved efficacious, and he would be at a loss to replace it as a means of treatment in cases of this most refractory condition. He has found the dose to be variable, in some cases, the amount required to produce the desired action being considerably greater than in other cases, without any appreciable difference in the patients. The dose which had often proved useful in his observation is ten drops, which is soon reduced to five drops, and, after a few days, is discontinued entirely.

DR. C. P. PUTNAM asked the reader if the other ingredients of the cordial of cascara aided or benefited the action of the cascara itself in its effect upon the system.

DR. FARLOW said that, in a composite mixture, such as the cordial of cascara is, the action of the substance is not so easily determined, and he much prefers to use the drug in its simple form, in order to eliminate all but the effects of the remedy with which he is experimenting. When the drug is employed in the treatment of children's diseases, there is no doubt that the cordial is a better form for administration.

DR. BLODGETT asked the reader if the drug, as furnished by the pharmacists, is of uniform quality, and reliable in its activity.

DR. FARLOW replied that he has had no trouble with any of the standard preparations of this drug, as manufactured by responsible firms. He mentioned

[1] See page 402 of the Journal.

Parke, Davis, & Co., Squibb, Metcalf, and a few others, whose preparations he had found to be reliable, and of uniform character.

Dr. Langmaid asked Dr. Farlow if he was aware of any physiological experiments tending to determine what part of the intestinal tract is specially acted upon by this drug, or in what portion of the bowel its elimination takes place.

Dr. Farlow replied that no experiments of this character have been made in relation to the present variety of this plant, rhamnus frangula.

Dr. C. P. Putnam stated that he had used cascara to some extent, but had obtained only a variable and uncertain result. It is, therefore, a great satisfaction to have the results of long and careful observation and use of the drug, as contained in the concise statements of Dr. Farlow, and particularly, to know that no untoward results attend the employment of a comparatively new remedy. In some recent contributions upon this substance, it was stated that the preparations had not proved efficacious. Is the degree of constipation which exists in any way a guide to the dose of cascara which should be prescribed in a given case?

Dr. Farlow said that he knew no guide to the exact amount which would be required in any case, but each patient must try the drug in a dose of moderate character, and increase or diminish the amount, as the case requires. Dr. Landowski, who introduced it into France, and who experimented largely with it in the clinic of Dujardin-Beaumetz, as did also Dr. Eymeri, draws the following conclusions as to its use:[2] The medicine purges easily, generally without colic, at a relatively small dose. Its use not only does not excite anorexia, but, on the contrary, it excites the appetite; which is especially worthy of remark: at the end of ten or fifteen days of its employment, one can often stop the medicine without the constipation beginning again. If, at the end of a certain time, the constipation sets in again, one has only to take the medicine again for three or four days. He thinks it particularly good in cases of intestinal atony, and, when it succeeds, he does not know of any better means of combating obstinate constipation.

Dr. Senator[3] considers it an unirritating, safe, painless purgative, which, according to the dose, causes normal or loose, seldom watery stools, and can be given a long time without harm.

Dr. J. Fletcher Horne,[4] who has used it in several hundred cases, thinks it a very valuable remedy, and that constipation is often cured by its use.

Dr. P. C. Knapp then read a paper upon

THE MEASUREMENT OF THE GALVANIC CURRENT, WITH SOME REMARKS UPON ELECTRODES.[5]

Dr. J. J. Putnam said that the present paper is a valuable contribution to the study of electro-therapeutics. The capacity to use figures and formulæ advances the usefulness of the remedy. What we really measure is, however, the current in the electrodes, but the absolute density of the electrical current in the tissues varies with the distance from the electrodes. Experiments with small electrodes over the track of nerves have shown that we cannot determine with accuracy the amount of electrical action simply from the size of the electrode.

[5] See page 399 of this number of the Journal.

Dr. A. C. Garrett thought that the subject is a very important one, and one which has not been well understood. He is strongly opposed to the present form of electrodes, and spoke warmly in favor of a large number of electrodes, so that the same electrodes may not be employed on successive patients. He thinks that the use of ordinary sponge-electrodes is fraught with danger, both from the filthy condition which is sometimes observed on the electrodes themselves, as well as from the danger of communication of diseases by their use. The idea that we can measure the current of electricity which the patient is receiving is recent. We formerly had no correct method of ascertaining the amount of the electrical influence to which the patient was subjected. The first attempt at ascertaining the degree of electricity was to measure the battery. This was the only means at that time known, and gave rise to the estimation of the power of the battery by the number of cells comprising the battery.

There is no doubt that the best results are obtained from wet electrodes upon the skin. The use of tin-electrodes is to be discouraged for many reasons. These are the variety usually supplied with batteries, as sent from the manufacturer.

The next paper was by Dr. Albert N. Blodgett, entitled,

A CASE OF AGORAPHOBIA.[6]

Dr. Knapp said that although he had never happened to see a case of true agoraphobia, he occasionally met with cases of *folie du doute*. The various forms of morbid dread, agoraphobia, claustrophobia, mysophobia, anthropophobia and the like, are all forms of one general psychosis which is termed *folie du doute*. In the various cases reported there is no particular diathesis as a foundation for the psychosis, nor, in the cases of agoraphobia reported by Westphal was there any trouble with the organs of special sense to account for the symptoms. Westphal's cases differed from the case reported in the entire absence of vertigo. Its presence in this case is certainly of interest. Agoraphobia,— and the allied form of *folie du doute* is a form of psychical degeneration of the milder type, not depending upon any discoverable brain lesion, but found especially in those of a neurotic tendency, and is one of the slight indications of that degeneration of the higher cerebral faculties which is seen in its more pronounced forms in paranoia.

The cases reported are very curious. One patient expressed his utter inability to cross an open space, by saying that if he were perishing by thirst, and a spring of water was across a clear space twenty feet wide, he would die before he could cross it. The sensation of dread has been likened in degree to what we should feel in falling from a great height. One of Westphal's patients recovered while in the mountains, where the hills shut off the horizon, but relapsed on going on a picnic down into a plain. Another could cross a square, if there were a lamp-post in the middle, or could cross a park where there were trees and shrubbery. Another could cross behind a wagon, or in company, or if he saw the red light of a restaurant in the distance. These peculiar variations go to show that the disorder is purely mental.

Dr. T. W. Fisher stated that he had seen a few

[6] See page 407 of the Journal.

cases of this disease, though it must be ranked as a rare condition. The disease is purely a mental disorder, and is now generally recognized as such. The panic into which the patient is thrown is something painful to observe, and once seen is not to be forgotten. Such a case was for a time under the observation of DR. Fisher, at the South End, in this city. The patient lived upon one of the streets near Franklin Square, and was obliged to cross this square on his way to take a car for his place of business in the lower part of the city. This small open square was a source of such terror to the patient that he would not cross it alone, but it was necessary for his wife to accompany him to the car, when he made the remainder of the trip without further disturbance, and on reaching the Square at night on his way home, his wife always was there to escort him to his home. The patient was otherwise in good health, and followed a responsible occupation, that of book-keeper in a large house.

There was no tendency to any further development in the disease, and no other symptoms were ever observed in the further history of the case. This disease does not tend to assume any more serious condition. Sometimes, by attention to hygiene, an improvement may be effected in the disease, but there is usually little hope of a diminution of the terror which the presence of the patient in an open space produces in these susceptible persons.

DR. F. W. PAGE exhibited a

GALL-STONE,

which weighed about twenty-three grains, and which had been successfully expelled by a patient after an impaction of eighteen months. He said that he was induced to do so, not so much on account of its size, as there were many on record of much greater weight; notably one recorded by Horly weighing four hundred grains, and another, found post-mortem, weighing four hundred and eighty grains: but he did so because of two interesting features connected with the case; to wit, the length of time, eighteen months, the calculus had remained in the common duct, giving rise to symptoms of obstruction; and from the peculiarity of the symptoms, associated with periodical discharges of bile, the modifications of diagnosis, and because of the peculiar mental condition the obstruction developed, aside from the temporary delirium it occasioned, and which was unquestionably due to bile poisoning.

The patient, a female, fifty-one years of age, previous to the attack, which was the beginning of her illness, had been in good health, was active in work at home and that connected with various charities, both private and public, and weighed 267 pounds. In October, 1885, she experienced without, so far as she knew, obvious cause, a severe attack of pain referred to the liver, and which extended to the umbilicus. This pain was immediately followed by jaundice, and pipe-clay colored stools, which persisted with varying modifications of intensity of the hue of the skin, pain, disturbances of digestion and constipation, with whitish dejections until the following July, when she came under my care and observation. At that time she had already lost eighty-four pounds in weight, and was losing at the rate of a pound a day. Her conjunctivæ and skin were icterode, *the latter* not deeply so, owing to the fact that her kidneys were active and the flow of urine free, about forty ounces daily. There was no vomiting nor nausea, although she had daily attacks of pain. There was considerable tenderness over the liver, circumscribed in limit, and corresponding to the region of the gall-bladder and common duct. The liver measured in mammary line four and one-half inches. It was represented that no bile had been seen in the dejections since the first attack of hepatic colic in October. But this may be questioned on account of the slight enlargement of the liver at this time, nine months later. The patient was placed upon a purely milk diet and the so-called alkaline treatment; to wit, bicarbonate soda, sulphate soda, etc., in varying doses, and modifications, in order not to disgust the patient, and was steadily adhered to to the end. All dejections were carefully sifted. In the early part of September, 1886, a few black particles were found in the dejections, resembling grains of gun-powder, and which proved to be inspissated bile. A few days later, many more were found in a bilious discharge, some very dark, others lighter in color. The larger ones, on the addition of sulphuric acid, gave under the microscope, cholesterin crystals, which confirmed the diagnosis of obstruction from gall-stone. Despite this, nothing more was obtained until the final expulsion, here exhibited, although a small amount of bile would be occasionally seen in some of the dejections. The patient remained in a variable condition, steadily losing in weight, suffering much from flatulence, occasionally overstepping the limit in regard to diet and experiencing thereby attacks of hepatic colic, which were always followed by a deepening of the icterode condition of the skin, until November 16th, when after eating surreptitiously a plate of beans, she had an unusually severe attack of pain, but without either vomiting or nausea. This was followed by a rise of temperature, 104.5° F., accelerated pulse 120, delirium and within a few days by sordes upon teeth and tongue; before the subsidence of these symptoms, the peculiar mental state, before alluded to, supervened. This was characterized by delusions of suspicion respecting her family, and was associated with hallucinations of sight and hearing. This aberration persisted until February, when improvement began, first, respecting the hallucinations, and later in regard to the delusions. Until the latter part of April she remained in much the same condition as before the development of the mental disturbance, save that there had been a slow but steady loss in weight. At this time, about April 26th, she experienced a severe attack of pain, which was modified but not wholly relieved by morphia, and which lasted throughout the night. Two days later the concretion was successfully voided per anum, and is a beautiful specimen of a biliary calculus. An examination of it under the microscope, on the addition of sulphuric acid gives the characteristic cholesterin crystal of gall-stones. The total loss of weight of patient for the entire period of eighteen months was about 127 pounds.

DR. C. H. COOK, of Natick, exhibited a

GALL-STONE,

which was passed by a lady forty-five years old, who had symptoms of its presence only from March to October in the year 1879. During this time she had lost fifty pounds in weight, and suffered much from vomiting, anorexia, constipation, etc., and presented an enlargement in the right side in the region of the liver,

which was the seat of discomfort but not of severe pain. The diagnosis was between cancer of the liver and impacted gall-stones.

In August there was an accession of severe pain, accompanied a few hours afterward by severe diarrhœa, which was followed by entire relief from all the symptoms before noticed in the abdomen. Two weeks from the onset of the acute symptoms, the patient passed the gall-stone shown, and all the severe features of the case vanished, and have never recurred. The patient is now living, and has regained her original weight, and is in good health. The weight of the stone is 132 grains.

The late Dr. Ellis was consulted in relation to this interesting case, and expressed the opinion that a stone of the size of the present one could never have been passed through the normal duct of the gall-bladder, but that when the acute symptoms, above mentioned, came on, there was developed an acute localized adhesive peritonitis, by which the adjoining structures were united to the gall-bladder. The gall-bladder then probably ulcerated, and by good fortune when the opening in its wall occurred, the perforation was not into the cavity of the general peritoneum, but into the lumen of the intestinal canal to which the gall-bladder had become adherent. The stone, therefore, passed from the gall-bladder directly into the bowel at a point much lower down than the opening of the gall-duct into the duodenum, and was then soon evacuated with the stool.

The stone has roughly the shape of a bee-hive, and is about three-fourths of an inch in diameter, by about one inch high. The base of the stone is somewhat hollowed out by contact with another concretion, but the apex is conical and symmetrically rounded. There would seem, then, to have been at least one other stone in the gall-bladder of this patient, which probably was also passed into the bowel through the adventitious opening, but which was lost. It is also probable that only two stones were present in this case.

The Secretary stated that since the last meeting both the Chairman and the Secretary had been in receipt of communications from the public in relation to the question of milk-supply, and that the action of the Section at its last meeting had seemed to awaken considerable interest in those concerned in the milk-business. The Secretary suggested that a Committee be appointed to take the matter into consideration, and report what further action the Section might properly take in the matter.

The suggestion was put to vote and passed. The Chairman appointed as that Committee the following gentlemen, members of this Section: Drs. Henry J. Barnes, E. W. Cushing, C. P. Putnam.

Voted to adjourn.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.

W. H. TAYLOR, RECORDING SECRETARY.

THE meeting was called to order at the rooms of the Boston Medical Library Association, October 5, 1887, at 12.30 P. M., by PRESIDENT WINSOR. Sixteen members were present.

Records of the last meeting were read and approved.

On recommendation of the Executive Committee, Medical Examiner G. G. Bulfinch, M.D., of Southbridge, was elected a regular member of the Society.

Medical Examiner DRAPER, of the committee to submit a blank form for autopsy returns, asked for more time, as suggestions from medical examiners had been few in number.

Voted to grant the committee more time.

Medical Examiner WINSOR, of the Committee on Expert Medical Testimony reported verbally that the Judiciary Committee of the Legislature had granted leave to withdraw the submitted bill. He believed that the failure of the bill was due to the apathy of the bench and bar, and not to lack of support from medical men.

The President acknowledged receipt of Volumes 4 and 5 of the Transactions of the New York Academy of Medicine, from the Librarian of that body.

Voted to supply the Librarian of the New York Academy of Medicine with copies of the Transactions of our Society, as far as possible.

Medical Examiner PRESBREY read a paper entitled

A CASE FOR THE MEDICAL EXAMINER.

An unmarried domestic, aged twenty-one, apparently robust, with no suspicious surroundings, was found dying in a tub which contained a small quantity of water, prepared for bathing. Her head was hanging over the edge of the tub, and had not been immersed. She was put to bed, and expired in a few minutes. Autopsy and chemical examination revealed nothing but an undisturbed fœtus of two-and-one-half months. No attempt at abortion had been made, and there were no marks of violence, externally or internally. Medical Examiner Presbrey reported the death as having occurred from some unknown natural cause.

Medical Examiner HARTWELL reported a sudden death from uræmia, in a woman four months pregnant.

Medical Examiner DRAPER inquired as to the condition of the pancreas.

Medical Examiner PRESBREY had not noted anything peculiar about this organ.

Medical Examiner TAYLOR suggested syncope in the bath, from heart failure.

Medical Examiner PRESBREY had not considered the heart-muscle fatty.

The case was further discussed by members Bemis and Gleason.

DR. S. W. ABBOTT presented some statistical information of interest, abstracted from medical examiners' returns and other sources.

Adjourned.

NEW YORK NEUROLOGICAL SOCIETY.

MEETING held Tuesday evening, October 4, 1887, DR. C. L. DANA in the chair.

ARTHROPATHY OF TABES.

DR. WM. H. PORTER presented a specimen of the cord and knee-joint from a case of tabes. The patient was a female, thirty-two years old. The family history was good. There was no alcoholism, and no history of rheumatism in the case. In May of the present year, ovariotomy had been done, and, with the exception of a ventral hernia, the patient had made a good recovery. The cord affection dated from five months previously, and in February last, a gradual increase in the size of the knee had been noted. As early as December 15th, however, the patient had suf-

fered pain, and partial luxation had made standing difficult. Examination showed the right knee painful, but not swollen. The left presented subluxation, some fluid, and enlargement of the lower portion of the femur. There was some dyspnœa and some headache. The patient also suffered with external hæmorrhoids, but the urine was negative, and the coördination good. The right knee measured eighteen inches, and the left twenty-one-and-one-half. The patient was a large woman, weighing three hundred pounds. The enlargement, and the riding of the patella upon the joint, were all of the positive symptoms in the case, and it was transferred to the surgical ward. There continued to be a great deal of boring pain in the knee, but no puffy feeling in the feet, no anæsthesia, and no ocular trouble. The joint was excised, with an apparently good result, but three weeks later, on August 10th, discoloration of the skin of the buttocks and of the small of the back appeared, and, in the course of a day or two, the part sloughed. The woman died, apparently of sepsis from the slough. *Post-mortem*, the viscera were found healthy, with the exception of the liver, which was pock-marked with cicatricial depressions. The right knee-joint was found in a good condition. Moderate changes of interstitial thickening were found in the cord. The question was whether this should be considered a case of ataxia, the only positive symptom being the boring pain. The supposition of tuberculosis was entertained, but the excised joint had failed to show tubercular tissue or bacilli, and erosion of the bones had been the only discoverable change.

Dr. Dana added that the cord in this case was now being examined by Dr. Graeme Hammond, and there was no doubt that the posterior columns, particularly the postero-external columns, or columns of Burdach, were affected. It was a case of sclerosis of the cord, most marked in the posterior columns.

Dr. W. A. Hammond suggested that articular affections with locomotor ataxia were infrequent in this country, compared with France. He had never seen a case, although many cases of locomotor ataxia had passed under his notice. According to Charcot, they were very common, resembling in this the grand hysteria, which also seemed limited to France, and even to the wards of the Saltpetriere Hospital.

Dr. Porter stated that, during the past year, he had made post-mortem examinations in four cases of locomotor ataxia. In two of these there were joint-affections, and in two none.

Dr. Hammond asked whether the joint-affections were recognized during life.

Dr. Porter replied that they were recognized only in one of the cases. He had never seen the condition before this year.

Dr. Weber referred to a case which had been presented the day before at the German Society. He had seen others, but not such as would answer to Charcot's descriptions. Rosenthal, of Vienna, also had described severe joint-affections in locomotor ataxia, but not in such great numbers. The speaker could point to a few cases out of seventy or seventy-five, but, as a rule, the affection was not destructive. It was acute. It would come and go, and complete restitution might occur. He referred to two cases. In one there was diabetes and locomotor ataxia, and in the other there was sclerosis of the cervical region of the cord. In this case, it looked as though the cartilage and bone were invaded, as there was crackling and change in form. A case like that referred to, as presented the day before, with intra-capsular fracture and such extreme mobility, he had never seen before in this country.

Dr. Dana, from an experience embracing two cases, found that the term tabitic arthropathy did not, under all conditions, mean the same. One of these, a case of ten years' standing, slipped and fell, nearly dislocating a joint already loose, so as to present a typical arthropathy of this disease.

MELANCHOLIA DUE TO THE PROLONGED USE OF MORPHIA.

Dr. S. B. Lyon presented the history of a case of melancholia following the prolonged use of morphia for the relief of cardiac pain. The patient was a female of fifty years, who, for three years, had suffered from a condition diagnosed angina pectoris, which morphia only relieved. From two to seven grains had been taken during the day. She had subsequently suffered with terrors and delusions similar to those of the morphia habit, but more persistent. Relief was obtained after withdrawal of the drug and removal to an asylum, away from the unwise attentions of her friends. The cure was sudden, complete banishment of her terrors and delusions occurring in a single day. A curious double consciousness characterized this case. While dominated by her delusions, she preserved her ordinary consciousness, thus appearing to inhabit in thought both a real and an unreal realm.

While insane, this patient was free from her cardiac pain. This subsequently appeared, but yielded to electrical applications.

Dr. Putnam Jacobi considered the case very interesting. The conception of the Ego as a simple unit is childish. Undoubtedly, there may occur changes in the groupings which go to form the consciousness of which the Ego is made up. In this case, there was destruction of the ordinary linkings of consciousness, and the replacement of the ordinary normal impressions by the formation of a new sphere. The aberrations produced by morphia and other toxic influences could be similarly explained. The suddenness of the recovery in this case further demonstrated that the forced paths of association had ceased to be travelled, and the old ones resumed — a process which might be likened to the switching of an engine from one track to another.

Dr. W. A. Hammond objected to the term double consciousness in connection with the case. Double consciousness might be represented by plus and minus. The patient was not at the same moment in both conditions, but at different periods led separate lives, during the plus condition knowing nothing of what occurred during the minus condition, and vice versa.

Dr. Spitzka thought that the reader of the paper had used the term with the meaning of the French. The case was assuredly not one of double consciousness as the term is used by alienists. In double consciousness there is really a double *Ego* with alternate consciousness.

Dr. Lyon recognized that the case was not one of double consciousness as Dr. Hammond and Dr. Spitzka had used the term. The patient had, however, a double consciousness in an ordinary acceptation of the word, with a real and an unreal aspect, the latter dominating.

DISCUSSION UPON THE USE OF ANTIPYRINE AND ANTIFEBRIN IN NERVOUS DISEASE.

DR. J. S. ROBERTSON opened the discussion. He had used antipyrine first in general practice, in acute rheumatism, where it had appeared not only to reduce the fever, but to control the pain. This led him to try it in a case of migraine which had resisted aconitia and chloral. He had subsequently given it in one hundred unselected cases. In ninety per cent. of these, relief was obtained in fifteen to forty-five minutes. He gave it without a stimulant, and diaphoresis was the only ill effect which he had seen.

In the severe pains of tabes he had given ten to twenty grains hypodermically, or twenty to thirty by the mouth with a resulting diminution in frequency. In insomnia the sleep was better than that obtained by chloral. The speaker had never seen heart failure. In hyperpyrexia he gave forty grains in a dose, and had himself taken one hundred and twenty grains during twenty-four hours without any unpleasant result.

DR. E. WAITZFELDER had had an experience somewhat similar to Dr. Robertson's, but gave the drug with a stimulant, having found nausea and vomiting common where this was not used. He had given antipyrine in twenty indiscriminate cases of headache, obtaining relief in about fifty per cent. He had directed its use in the epileptic ward about three months ago. It had been thoroughly tried but without any appreciable effect. He had used it for the pains of locomotor ataxia, but while the patient had improved he did not attribute this to the drug.

DR. W. A. HAMMOND used antipyrine, and his experience had been entirely negative. He had given both antipyrine and antifebrin, both singly and combined, in neuralgia, the pain of locomotor ataxia, insomnia, vertigo, and in headaches both of the anæmic and hyperæmic variety. His method of administration has been in fifteen-grain doses three times a day continued for from two to three weeks. A new drug was not needed to shorten an attack of migraine. A hypodermic injection of morphia would do it, or one hundred grains of bromide of sodium, or 1-100 grain of glonoin, according to the variety. In a case of tuberculous meningitis in a child of two years he had given four-grain doses of antipyrine for the relief of pain and had signally failed. He had given it in epilepsy without result.

DR. DANA asked whether Dr. Hammond had given antifebrin in epilepsy. Dr. Hammond had given both antipyrine and antifebrin in fifteen-grain doses with similar results, sometimes combining seven and one-half of each. He referred to the insolubility of antipyrine, making administration difficult.

DR. GEO. W. JACOBY thought it serviceable to hear the other side of this question. His own experience had resembled that of Dr. Hammond. Antipyrine gave some relief in migraine, at least following the first or second administration. It sometimes cut short insomnia, but that about limited its usefulness in this field. It was not without danger. He had seen collapse from a dose of twenty grains.

DR. PUTNAM JACOBI has given antifebrin in the Infirmary to a child with pleuro-pneumonia, and with lowering of the temperature relief from pain also was obtained, although the physical signs remained unaltered and defervescence occurred in a typical manner upon the sixth day.

DR. SACHS believed that antipyrine could be recommended only in migraine. Possibly, also, in headache of a neurasthenic type. Cases should be followed for a number of months. The results from two to three administrations should not be relied upon. He had given it in a dozen cases of migraine with relief within twenty minutes of its first exhibition, and in no case had it been necessary to repeat the dose more than two or three times at intervals of an hour. The only unsatisfactory cases had been those of the spastic type. The paralytic type had been in every case relieved. In one case, that of a man of thirty-two years, the condition had resisted all previous treatment. The patient every four weeks had to go to bed from twelve to thirty-six hours, and was incapacitated for work for several days. Antipyrine does not entirely relieve the headache in this case, but the patient is able to continue his business during the paroxysm. In the speaker's experience about twenty per cent. of the headaches of neurasthenic origin would be relieved. In headaches of anæmic and gastric origin the treatment has been unsatisfactory. In insomnia, with and without migraine, antipyrine had appeared to act as a true narcotic. Sleep of nine and one-half to ten hours followed the administration of two grains. He had used it in the lightning pains of locomotor ataxia and in peripheral neuralgias, particularly trigeminal and sciatic, without result. Antipyrine was not a panacea, and the speaker thought that it should be used carefully. He had met no bad results himself, but from the reports of others it was evident that such results could occur.

DR. DANA expressed surprise that Dr. Hammond had been so unsuccessful in the use of antipyrine, and suggested that he keep a closer watch upon his clinical assistants. Dr. C. H. Brown claimed to have been cured of a most violent migraine by antipyrine, and was enthusiastically prescribing it in Dr. Hammond's clinic. In the treatment of epilepsy, antipyrine could only be used empirically. Antifebrin, on the contrary, has been shown to act as a spinal depressant, and hence could be rationally prescribed.

DR. ROBERTSON closed the discussion with the remark that he had found antipyrine soluble in Vichy. He considered a dose of twenty to thirty grains safe. He had not claimed that it cured, but that it acted as a palliative in the conditions named.

DR. SACHS exhibited a papier-maché model of the brain, in the absence of Dr. Starr.

—The *American Lancet* considers that one effect produced on the local practitioners by the presence of a medical school in a town is a demoralizing reduction in the fees received for medical attendance. It cites for comparison the two cities, Jersey City and Cleveland. New Jersey has no medical school, and Ohio has sixteen, of which Cleveland possesses several. The comparison of fees is much to the disadvantage of Cleveland, a sample of a large number being that ordinary midwifery cases in Cleveland are from five to ten dollars; in Jersey City, ten to thirty dollars. We suspect that there are other causes of difference, one appearing to be that the published "fee-bills of the New Jersey State Medical Society" are compared with the "fees charged by the Cleveland profession as a rule."

THE BOSTON

Medical and Surgical Journal.

THURSDAY, OCTOBER 27, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

THE ARMY HOSPITAL CORPS.

IT may possibly remain in the minds of some of our readers that we have, on a former occasion, spoken of the desirability of a separate organization of a Hospital and Ambulance Corps for the Army. The necessity for a distinct organization, composed of men specially enlisted for such a corps, and under the immediate control of the medical staff, was abundantly demonstrated during our late war.

The last Congress passed an act providing for a Hospital Corps, and General Order No. 56 has just been issued from the headquarters of the Army containing a long series of rules and regulations for its government.

The Hospital Corps is to consist of hospital stewards, acting hospital stewards, and privates. All hospital services in garrison and in the field are to be performed by its members, who are to be regularly enlisted and permanently attached to the Medical Department. In time of war, the Corps is to perform the necessary ambulance service under such officers of the Medical Department and assistants as may be detailed to direct it.

Candidates for the position of acting hospital steward must pass a satisfactory examination as to physical condition and general fitness, and, in addition, in pharmacy, care and use of meteorological instruments and hospital and field appliances, the methods of rendering first aid to the sick and wounded, and the ordinary modes of cooking. No person shall be appointed a hospital steward until he has demonstrated his fitness for the position by service of not less than a year as acting hospital steward, and, in addition, he must pass an examination in the elementary principles of hygiene, including ventilation, heating, and disinfecting, the principles of materia medica, therapeutics, and minor surgery, and the administration of anæsthetics. Their duties are, in brief, to care for hospital property, distribute stores and supplies, and supervise the Hospital Corps in hospital and in the field. The privates of the Hospital Corps are to be enlisted like other enlisted men of the Army, but are to be taken by preference from men who have served, at least, one year in the line, preferably as company-bearers, and they must pass an examination as to general intelligence and aptitude for the duties which they will be expected to perform. Privates enlisted for the Hospital Corps who have not received, at least, one year's military instruction in the Army, shall serve as privates for that period in a company stationed at one of three designated forts. After one year's service in the Hospital Corps, privates who have displayed particular merit will be recommended for promotion, and from those thus recommended, acting hospital stewards will be appointed. Members of the Hospital Corps will be instructed by the medical officers in the duties required of them, and will not be required to perform other military duties than those pertaining to their corps.

From each company of the line, four privates are to be selected by the company commander, with the concurrence of the post-surgeon, as "company-bearers." These men are to be instructed, under the supervision of the surgeon, in the duties of litter-bearers, and in first aid to the sick and wounded, but shall not be relieved from their regular military duties, the object being to insure the constant presence with the company of a number of men who can, in emergencies, render temporary aid. During an engagement, the company-bearers shall render first aid to the wounded, or carry them to the rear, until relieved by members of the Hospital Corps.

At every post, the Hospital Corps will be represented. The very least representation at the smallest post, being one hospital steward, three privates, and one regulation ambulance.

Article 25 of the rules and regulations will be recognized by surgeons of the late war as of special importance. It is as follows:

"The ambulance and harness shall be under the immediate control of the senior medical officer of the command, and shall not be used for any purpose other than the transportation of the sick and wounded, the recreation of the convalescent patients in hospital, or to enable the medical officer to give instruction in the duties of the ambulance service"; and paragraph 41, relating to ambulance service in time of war, reads: "Ambulances shall be used only for the transportation of the sick and wounded, and, in urgent cases only, for medical supplies; and all persons shall be prohibited from using them, or requiring them to be used, for any other purpose. It shall be the duty of the officers of the Ambulance Corps to report to the commander of the Army Corps any violation of the provisions of this paragraph; and any officer who shall use an ambulance, or require it to be used, for any other purpose than as provided in this paragraph, shall, for the first offence, be publicly reprimanded by the commander of the Army Corps in which he may be serving, and, for the second offence, shall be dismissed from the service.

The regulations go on to prescribe still further their duties and their distinctive uniform, but enough has already been said to show that the Corps is to be established on a distinct and permanent basis, and we have no doubt, that the corps will fully justify its creation even if active service in the field should never be required of it.

ANOTHER NEW TREATMENT OF TUBERCULOSIS, BY SULPHUROUS ACID FUMES.

It is probable that, as long as the bacillary theory of phthisis has possession of the medical mind, there will be no cessation of attempts to attack the specific microbe, either by the breath or through the blood. Great expectations were entertained of gaseous rectal injections, and it was fondly hoped that few of Koch's baneful parasite brood would be able to withstand that mephitic hydrogen sulphide, attacking them, not *a fronte* (which would be hardly safe for the patient), but *a tergo*, during which process the bacilli would stand a chance of being drenched with the foul gas while taking its departure from the pulmonary cells. It can hardly be said that these expectations have been realized; the bacilli do not die, but swarm in the sputa, as numerously as ever. Such is the testimony that comes to us from experts, both at home and abroad. In fact, Bergeon's method seems already to be on the wane, despite some temporary advantages which are still claimed for it in some quarters.

More noxious to vegetative life even than sulphurretted hydrogen, is sulphurous acid, whose anti-parasitic and disinfectant properties have long been known. It has, of late, been proposed to utilize this substance in the combat with Koch's bacillus, and, in the few instances of undoubted phthisis where it has been tried, it would seem really to have done pretty thorough work with the microbe-enemy, *if we may trust the reports.*

Experiments with sulphurous-acid inhalations in pulmonary tuberculosis date from the communication of Dr. Sollard to the Academy of Medicine, March 8, 1887. In this communication, Dr. Sollard reports the radical cure of a case of phthisis as the result of prolonged sojourn in a sulphurous atmosphere. The patient was a marine officer at Cherbourg. He had all the signs of confirmed phthisis; there were, besides, abundance of the characteristic tubercle-bacilli in his sputa. Repeated daily inhalations, four hours at a time, of the fumes of burning sulphur, in a close room, cured him of his disease; there was a total disappearance of all the stethoscopic signs, of the constitutional symptoms, and of Koch's bacilli. Since then, Balband, of Cherbourg, has tried this method in eight cases, reported in the *Bulletin Général de Thérapeutique* (October 1st). In all these there has been much improvement after four months' treatment, although the Cherbourg physician has not noted any marked diminution in the quantity of tubercle-bacilli in the sputa. Moreover, Dr. Auriole, of Bellegarde-du-Gard, has recorded seventy trials of these inhalations in as many phthisical patients, and claims cures in some cases, and amelioration in all.[1]

Sollard advises the following mode of procedure: "In a close room, burn a quantity of sublimed sulphur equal to from ten to twenty grammes per cubic meter; then wait twelve hours, and, without opening the doors or windows, admit your patients, and make them sojourn eight hours in this room." Dujardin-Beaumetz, who has made trials of this method in Cochin Hospital, admits his patients to the sulphurous fumes two hours after the combustion of the sulphur, of which he uses, first five, then ten, then fifteen, then twenty grammes per cubic meter. The patients are kept four hours in this room. "Under the influence of this treatment," he says, "we observe a speedy change in the sputa. The cough diminishes, and the patients sleep much better. They also have a better appetite."

It might be supposed that these sulphurous inhalations would be very irritating to the weak lungs of the phthisical, that coughing would be promoted, and that hæmoptysis would be excited. It would seem that none of these fears have been realized. Naturally, apyretic cases have been chosen as the subjects of this experimentation.

MEDICINAL LIQUID VASELINE.

A NEW VEHICLE FOR HYPODERMIC INJECTIONS.

HYPODERMIC medicine seems likely to realize an immense extension in the use, as an excipient for medicinal substances which it is desired to introduce subcutaneously, of a petroleum product which comes from Europe, and especially from the mountainous regions of Russia, and is known as *liquid vaseline.* This is one of the final products of the distillation of petroleum — coming over after paraffine — and is purified by filtering through animal charcoal. Its solvent powers are immense, multitudes of vegetable and mineral substances readily dissolving in it, and what renders this oil especially valuable is that it is not only unirritating of itself, but it so sheaths and modifies medicaments of a locally irritant character (rendering them bland) as to constitute them suitable and safe for hypodermic use.

Among the substances soluble in liquid vaseline, we may enumerate, eucalyptol, iodoform, turpentine, phenol, thymol, iodine, menthol, chloroform, ether, salol, sulphide of carbon, sulphuretted hydrogen, myrtol, cocaine, atropine, aconitia, caffeine, calomel, phosphorus, bromine, etc. Dr. Albin Meunier has most patiently and successfully worked out the requisite formulæ for hypodermic injections with liquid vaseline for their basis; among these formulæ none seems to have given better satisfaction in pulmonary and bronchial complaints than the combination of eucalyptol with liquid vaseline; one part of the former to five of

[1] Bull. Gén. de Ther., t. cxiii, p. 166.

the latter. Five cubic centimetres of this solution are injected into the gluteal region night and morning, and under this treatment has been noticed a marked lessening of the cough and expectoration. A two-per-cent. solution of iodine in liquid vaseline is highly spoken of in asthma, emphysema, the uric diathesis, etc.; the dose is one syringeful, to be injected into the outer part of the thigh. A twenty-per-cent. solution of chloroform is recommended to be injected in sciatica and other painful affections, and a ten-per cent. solution of salol is well spoken of in sciatica. The injections must be made deeply in the muscles. There are formulæ for bromine for antisepsis in diphtheria, and calomel for administration in syphilis.

Bourneville and Bricon have recently published a series of convenient formulæ, with liquid vaseline for basis, in their therapeutic manual, and the members of the Societé de Thérapeutique seem enthusiastic in their praises of the new mode of treatment, which bids fair greatly to add to our therapeutic resources by enabling us to use hypodermically multitudes of remedies which heretofore could not be administered in this way.

Liquid vaseline, according to Roymond, is the result of the depuration of the mineral oil of Baccou in Russia. In distilling this oil, several intermediate substances first come over (ethers and illuminating oils) finally paraffine and liquid vaseline. The Germans call the latter *liquid paraffine.*

MEDICAL NOTES.

— Since the last report one new case of cholera has developed among the *Alesia's* passengers detained under observation on Hoffman's Island, New York Harbor. The case is a child, several other members of whose family had the disease.

Another Italian emigrant steamer, the *Britannia*, was detained under observation in New York harbor, under suspicious circumstances, and two of her passengers are just reported as dying from cholera. There are now three separate lines of steamers, besides sailing vessels, plying between Palermo and Naples, and New York. These steamers, as a rule, make the round of the chief ports of Sicily,— Messina, Catania, and Palermo,— and then proceed to Naples whence they depart for New York.

These steamers bring very large numbers of emigrants from the lower classes in Italy, and under existing circumstances — notwithstanding the season of the year — they cannot be too carefully watched.

The United States Consul at Rome in a dispatch to the Treasury Department, dated Sept. 21st, says:

"Cholera has prevailed in certain parts of Sicily since the early spring. With the beginning of summer the disease appeared at some southern places on the mainland, also in the environs of Naples, and finally in that city early in August. Up to the present time neither the government nor other authorities give any information, statements, or bulletins concerning it, with the exception of in Sicily, from whence the associated press of Italy, under government surveillance, telegraphs daily showings for the chief cities of Sicily. Besides these chief cities — Palermo, Messina, and Catania — I have the best reasons for believing that many scattered cases of cholera are now occurring daily, not only in Sicily, but in many ports and places in the southern and central portions of the mainland, notably south of a line drawn from the Mediterranean opposite Rome across to Ancona, on the Adriatic. The various Mediterranean countries have now in force quarantines against Italy, extending from five to twenty-one days, for vessels from any port of Italy whatsoever. The sanitary measures of the Italian Government and local authorities are energetically enforced, and are deserving of every praise.

"During the last four years Italy has suffered so much from cholera and from quarantines, both foreign and domestic, that the present action of the government in withholding information relating to certain parts of the kingdom may be attributed to a desire to carry out the results of experience, and not to any lack of good faith. But at the same time it is true that as regards information relating to the disease on the mainland, no facilities are given for arriving at the truth. . . . There is now a quarantine observation of two days for detached soldiers on furloughs coming north of the line of railway between Rome and Ancona. Otherwise, there are no restrictions in Italy on commerce or travel by land or sea, except the prohibitory measures against old rags, already reported to the Department. Vessels communicate freely between the infected and non-infected ports of the kingdom."

— Up to October 21th, about one hundred and eighty cases of yellow fever had been reported at Tampa, Florida, with twenty-seven deaths. The construction of a temporary hospital building had been authorized by the Marine Hospital Bureau, and a sufficient staff of acclimated nurses to aid in caring for the sick has since arrived from Savannah. At the latest accounts the weather was reported as warmer and more unfavorable, and the disease as spreading in the better parts of the town and its suburbs.

— A contemporary tells the somewhat remarkable story of a physician who walked in his sleep, and at one time had a patient some two miles distant, about whom he was very anxious. It was in the coldest of winter. One evening he found his patient in a very unsatisfactory condition, and remarked to the family that if he did not find him better the next visit, he would change the medicine. On rising the next morning, he went to the barn to put his horse into the cutter. He was perplexed in finding his rigging somewhat misplaced, but supposed that some one had thrown it about in search of a missing article. On visiting the patient, he was gratified in finding a marked improvement. He inquired when the improvement commenced, and was answered, "Immediately

after taking the powders which he had given in the night." The truth flashed across him at once that he must have been there in the night. Concealing his emotion, he inquired with a careless indifference: "About what time was it when I was here?" They replied: "About two o'clock." This proved to have been the case, as he afterwards was told by the family where he boarded.

BOSTON.

— Dr. Joseph Bechtinger, is to give a lecture on "True Leprosy, its Forms and Varieties from Personal Observations in different Parts of the World: also on other medical subjects, to be illustrated by the stereopticon." The lecture is to be given in Parker Memorial Hall, Thursday evening, November 3d. Tickets may be obtained at the janitor's office.

— We referred last week to the difference between the cattle commissioners and the Cambridge railroad, regarding cases of alleged glanders in the horses of the company. Four of these animals were slaughtered on October 19th, and after the autopsy had been held a radical disagreement was found between Dr. Winchester, of the board, and Drs. Lyman, Harrison and Bryden, the veterinarians employed by the road, the latter gentlemen maintaining, it is said, that two of the horses had not been afflicted with the disease. It is reported that since the autopsy there is a difference of opinion between the members of the cattle commission as to the proper action to be taken by the board. Dr. Winchester stated that his examination, both before and after death, showed unmistakable evidence of glanders, and that a suspicion of the existence of this disease should unfit horses for work and association with healthy horses. In this view he claims to be supported by several veterinary surgeons who were present at the post-mortems. On the other hand, Messrs. Levi Stockbridge, and A. W. Cheever, the other members of the commission, acknowledge that the diagnosis of Dr. Winchester, based upon his ante-mortem and post-mortem examination, is correct, so far as these examinations have revealed certain characteristic marks, such as usually accompany chronic glanders, but, judging from the appearance of the quarantined animals, their general health and their ability to work, they maintain that the marks do not indicate their unfitness for service. The majority of the board, therefore, does not believe in the necessity of a wholesale slaughter. It was finally voted that a communication be sent to the Cambridge road, ordering the release from quarantine of ninety-five of the animals, and that the remainder of those in confinement, some sixty or seventy in all, be isolated in a separate stable, pending further examination, to begin on Monday, October 24th.

NEW YORK.

— Exercises will be held on the occasion of the opening of the new buildings of the Skin and Cancer Hospital, at the Country Branch, Fordham Heights, near New York City, Saturday afternoon, October 29th, at two o'clock. The exercises will consist of an address of welcome by the President of the Hospital, an address on Cottage Hospitals by the President of the Medical Board, Dr. A. Jacobi, reports of the Medical Board and the Treasurer, and addresses by Judge H. E. Howland and Rev. Dr. H. J. Van Dyke, Jr.

The Country Branch Hospital is situated at Fordham Heights, about one mile above High Bridge, between Sedgwick Avenue and the old McComb's Dam road, an hour and a quarter's drive from 59th Street entrance to Central Park.

— The following new appointments have been made by the Directors of the New York Post-Graduate Medical School and Hospital. Dr. Robert Abbe, Professor of Clinical Surgery; Dr. Henry D. Chapin, Professor of Diseases of Children; Dr. J. H. Girdner, Instructor in Clinical Surgery; Dr. O. M. Phelps, Professor of Orthopædic Surgery.

— St. Luke's day, October 18th, was celebrated at St. Luke's Hospital by the inauguration, with appropriate ceremonies, of an annex to the building which increases the accommodations for patients to about two hundred. The addition has been erected with a portion of the legacy of $100,000 left to the Hospital by the late William H. Vanderbilt. During the past year a number of free beds in perpetuity have been established by various other friends of St. Luke's, and the institution is in a flourishing condition. At the annual meeting of the St. Luke's Hospital Association, a rule was adopted, to the effect that in the future, applications for the position of attending physician to the hospital shall be received only upon condition that the applicant is not holding a position in any other hospital.

PHILADELPHIA.

— A complimentary dinner was lately given to Dr. J. Ewing Mears at the Hotel Bellevue. Professor J. M. Da Costa, M.D., presided, and a large number of the leading members of the profession were present.

Miscellany.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

A MEETING of the Executive Committee of the Congress of American Physicians and Surgeons, for the purpose of organization, was held on October 5th, in the Hall of the College of Physicians of Philadelphia. The special societies were represented as follows:

American Surgical Association, Dr. Claudius H. Mastin, of Alabama.

American Otological Association, Dr. Cornelius R. Agnew, of New York.

American Ophthalmological Association, Dr. D. B. St. John Roosa, of New York.

American Laryngological Association, Dr. J. Solis Cohen, of Pennsylvania.

American Neurological Association, Dr. L. Carter Gray, of New York.

American Dermatological Association, Dr. I. E. Atkinson, of Maryland.

American Climatological Association, Dr. A. L. Loomis, of New York.

Association of Genito-Urinary Surgeons, Dr. John P. Bryson, of Missouri.

American Association of Physicians, Dr. William Pepper, of Pennsylvania.

The Committee was organized by the election of Dr. Pepper as Chairman, and Dr. Bryson as Secretary.

It was decided to hold the Congress of 1888 in Washington, D. C., on Tuesday, Wednesday, and Thursday, September 18th, 19th, and 20th, respectively. The sessions of the Congress will be held in the evenings, leaving the mornings and afternoons free for the sessions of the special societies participating.

The following officers of the Congress were elected:

President.—Jno. S. Billings, M.D., LL.D., U.S.A., of Washington, D. C.

Vice-Presidents. — The Presidents-elect of all the participating societies.

Treasurer.— Dr. W. H. Carmalt, of Connecticut.

The arrangement of the programme for the sessions of the Congress was referred to the President, the Secretary, and the Chairman of the Executive Committee.

CÆSAREAN SECTION BY THE BISON'S HORN.

Dr. R. P. Harris has published in the July and the October numbers of the *American Journal of Obstetrics* a series of cases of the ripping open of pregnant women by the horns of animals. Ten of the rips opened the womb, three did not. The latter all recovered, did not miscarry, and bore living children at maturity. Of the ten hysterotomies, six women survived with four of the nine matured children. The last case, was personally witnessed by Dr. Powell, at that time a boy. A bison bull gored the abdomen of a squaw, tore out a fœtus and carried it on his horns some twenty yards. The child was of course killed, but the woman survived and made a good recovery under Indian treatment, which is as follows:

A plastic clay is selected, such as may in emergency be dug up from beneath a "buffalo wallow," and made into a stiff mud with water; the wound is held together, while a thick coating is applied; then over this is placed a layer of woody fibre crossed upon it in every direction: then another coat of mud, and so on, until a cake of two inches thick covers the abdomen from flank to flank, the patient being kept upon his back during the treatment. The Pawnees, Utes, Apaches, Sioux, and Comanches make use of silky fibres obtained from plants for holding the clay together. The sage-brush, so common in Indian regions, furnishes one source of supply; another is a species of evergreen, unknown by name to Dr. Powell, which grows high up in the snowy range of the mountains. In extraordinary years, the fall of snow reaches from twenty to forty feet in depth, covering the trees. The snow partially melts, then freezes, and finally sinks in the warm season, stripping down the bark to the roots, and tearing out the inner bark into long thin strips, which are gathered by the Indians for use in dressing wounds. Choice clays are also stored up and kept for the same purpose.

In 1865, Dr. Powell accompanied a United States expedition, with Omahas and Pawnees, across the plains, and encountered Black Bear and his band of Arrapahoes, on Tongue river, now in Montana. In hand-to-hand fights, three young braves in their teens, had their abdomens cut open, and in two the intestines protruded; whether in the third case the peritoneal cavity was opened he cannot say. These youths were treated by their companions in the way already described, and two of them recovered.

A Mexican correspondent of the same journal records another case in which a woman eight months pregnant was gored by a cow, the rent through the abdomen being eight inches long. A physician discovered the buttock of the child protruding, dilated the wound a little, and withdrew the child, which was living and unhurt. The womb at once contracted, with the placenta inside. He cut the cord as far down as possible, replaced it through the rent, and sewed up the abdomen. The placenta was delivered per vias naturales and the woman recovered, though after a violent peritonitis.

Such facts do not prove that the bison or the cow is a better performer of the Cæsarean section than a surgeon. They do show, however, that the mortality of the operation in strong healthy women, unexhausted by fruitless labor pains, need not be very high. The discouraging records of the operation are those furnished usually by rachitic or otherwise deformed persons in whom the operations were deferred to the last moment and then undertaken as a forlorn hope. Then if the bison's instrument for operation is not aseptic, the air of the prairies is, wherein it possibly compares favorably with the hospitals in which the more formal section is performed.

Correspondence.

STRYCHNIA IN SEA-SICKNESS.

Bridgeport, Conn., Oct. 21, 1887.

Mr. Editor,—The perusal of an article on the treatment of sea-sickness by strychnia and atropia in a recent number of your Journal, induces me to contribute an item in regard to the management of this distressing malady.

Some seven or eight years ago, while on a trip to Savannah, six of the lady passengers were severely attacked with sea-sickness when only about twelve hours out. Fully concurring with Dr. Skinner's theory of the pathology of the disease, I directed each patient to take one-fortieth of a grain of sulphate of strychnia every fourth hour. Five were well after the fourth dose, and remained so to the end of the voyage. The sixth was a delicate young lady, in the second stage of phthisis pulmonalis, and was so prostrated that actually I feared death by asthenia. She was panic-stricken and importuned so earnestly for immediate relief, that I substituted for the strychnia, twenty drop doses of chloroform in water. This only aggravated the symptoms, so I returned to the strychnia, and after a few additional doses she was well.

I have crossed the Atlantic six times, traversed the whole Atlantic coast from Florida to Halifax, made one trip to the Bermudas, incidentally treating many victims of *mal de mer*, and I am prepared to declare emphatically that strychnia, pushed if necessary, *ad tolerandum*, has accomplished more in my hands than any one or all other remedies. I have had no experience with atropia, but should anticipate from its centrifugal influence on the circulation that it would prove a good adjuvant to the strychnia. Cocaine, one-sixth to one-quarter of a grain, has proved an excellent palliative in my hands, but its influence, as also that of the bromides, has been transitory.

I have found no difficulty in my patients retaining the strychnia pellets or tablets, and, therefore, have not used it hypodermically.

Very truly yours, R. Hubbard, M.D.

GLEDITSCHINE-STENOCARPINE.

BROOKLYN, 314 State St., Oct. 15, 1887.

MR. EDITOR,—The fact, seemingly well proven by the experience of Drs. Seward, Claiborne, Knapp, Jackson, Mitchell and others, that the newly-discovered alkaloid, gleditschine-stenocarpine, is largely like cocaine in its power as a local anæsthetic, has prompted me to determine whether it has a value akin to the coca alkaloid, as a stimulant in the treatment of opium habitués, and I am now experimenting in this direction, using a two per cent. solution, exclusively by subcutaneous injection.

That cocaine, hypodermically, is a valued aid in treating the opiate neurosis, is beyond question, in my opinion, though it is not a specific, and should never be given, for this purpose, by the patient himself, be he physician or layman. Should gleditschine have a similar value, it may be found free from the ensnaring danger of cocaine, though, assuming the fact of its stimulant power, this freedom from risk will not be likely, and we shall note, probably, in the not far future baneful effects from its abuse, and gleditschine inebriety may be added to the list of toxic neuroses.

It has been stated by Dr. Seward that "he has observed antidotal effects to gleditschine from morphia," and Mitchell (W. H.) asserts, "it is a direct antagonist of morphia and opium, ten drops of the two-per-cent. solution neutralizing one grain of morphia or six of opium." Experiments on rabbits, now being made by myself, will, it is to be hoped, sustain these claims.

The two-per-cent. solution can be obtained from Messrs. Lehn and Fink, New York City, at a present wholesale cost of six dollars per ounce.

I shall be pleased to receive and report the experience which any reader of your JOURNAL may have on this subject.

Yours very cordially,

J. B. MATTISON, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 15, 1887.

Deaths reported 2.123: under five years of age 775; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 401, consumption 288, lung diseases 185, diphtheria and croup 103, diarrhœal diseases 109, typhoid fever 43, malarial fever 31, scarlet fever 28, whooping-cough nine, cerebro-spinal meningitis seven, measles five, puerperal fever five, erysipelas (New York) one. From malarial fever, New Orleans 15, New York seven, Brooklyn five, District of Columbia three, Philadelphia one. From scarlet fever, New York 10, Boston eight, Brooklyn six, Philadelphia, Worcester, Lowell and Cambridge one each From whooping-cough, Baltimore four, Philadelphia two, New York, Brooklyn and Boston one each. From cerebro-spinal meningitis, New York five, Springfield and Chelsea one each. From puerperal fever, Baltimore three, New York and Philadelphia one each. From measles, District of Columbia three, Boston and Cambridge one each.

In 22 cities and towns of Massachusetts with a population of 1,051,354; the total death-rate for the week was 18.92 against 20.71 and 19.26 for the previous two week.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending October 1st, the death-rate was 17.5. Deaths reported 3,097: infants under one year of age 774; acute diseases of the respiratory organs (London) 219, diarrhœa 168, scarlet fever 86, whooping-cough 58, fever 62, measles 39, diphtheria 36, small-pox (Sheffield 10, Bristow one) 11.

The death-rates ranged from 12.8 in Brighton to 31.6 in Preston; Birkenhead 15.5; Birmingham 17.7; Bradford 20 7; Halifax 25.7; Hull 17 3; Leeds 18.4; Leicester 17.5; Liverpool 21.0; London 15.4; Manchester 24.5; Nottingham 15.8; Sheffield 15.5; Sunderland 19.3.

In Edinburgh 16.7; Glasgow 17.1; Dublin 30.9.

The meteorological record for the week ending October 15, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Oct. 15, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 15, 1887, TO OCTOBER 21, 1887.

WOLVERTON, W. D., major and surgeon. Detailed as member of Army Retiring Board at Washington, D. C., convened by S. O. 78, A. G. O., April 5, 1887, *vice* Major C. C. Byrne, surgeon, hereby relieved. S. O. 241, A. G. O., October 15, 1887.

GARDNER, EDWIN F., captain and assistant surgeon. Relieved from duty at Fort Reno, Ind. Ter., and ordered for duty at Fort Lewis, Col. S. O. 241, A. G. O., October 15, 1887.

COCHRAN, JNO. J., captain and assistant surgeon. Now on duty at the Presidio of San Francisco, Cal., is assigned to temporary duty at Headquarters, Division of the Pacific, as assistant to the medical director of that division. S. O. 244, A. G. O., October 19, 1887.

EWING, C. B., first lieutenant and assistant surgeon. Granted leave of absence for one month, on surgeon's certificate of disability. S. O. 112, Department of Missouri, October 18, 1887.

APPOINTMENT.

JARVIS, NATHAN S., to be Assistant Surgeon, with the rank of First Lieutenant, October 14, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 22, 1887.

BEYER, H. G., passed assistant surgeon. Ordered to hold himself in readiness for orders to the "Trenton."

WHITE, S. S., assistant surgeon. Ordered to hold himself in readiness for orders to the "Trenton."

STEPHENSON, F. B., passed assistant surgeon. Detached from the "Bache," and ordered to the Navy Yard, Boston.

STONE, E. P., assistant surgeon. Detached from the "New Hampshire," and ordered to the "Bache."

STREET, T. H., surgeon. Detached from the "Patterson," and placed on waiting orders.

VACANCIES IN THE MEDICAL CORPS OF THE NAVY.

A Naval Medical Examining Board is now in session at the Naval Hospital, Philadelphia, Pa., for the purpose of examining candidates for admission to the Medical Corps of the Navy. Circulars of information can be obtained on application to the President of the Board. There are twelve vacancies in the list of assistant surgeons.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.— There will be a meeting of this Section on Wednesday evening, November 2d, at eight o'clock. Drs. J. W. Elliot and F. B. Harrington will read a short communication on "Dislocation of the Thumb," and will show cases. Dr. F. S. Watson will present a paper on "A Comparison between the Different Methods of Treatment of Stricture of the Male Urethra." In connection with the above, Dr. G. W. Allen will relate his experience in the use of electrolysis in the treatment of stricture.

G. H. MONKS, M.D., *Secretary*.

SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a stated meeting on Saturday, October 29, 1887, at 8 P.M., at 19 Boylston Place. Dr. J. Leslie Foley will read a paper upon "The Hair: its Diseases and Treatment." Dr. O K. Newell will show Leiter's Panelectroscope and his own improved Endoscopic Tubes, and demonstrate their use. Dr. G. W. Allen will show a set of Klotz's Endoscopes, and report illustrative cases. Report of Committee on Stenographer. Choice of a Committee of five to prepare a list of Candidates for Officers of the Society. Supper after the meeting. Members are requested to notify the Secretary of any change of address.

HERBERT L. BURRELL, M.D., *Secretary*.

A CASE OF PAPILLOMA OF THE MALE BLADDER SUCCESSFULLY REMOVED BY THE SUPRA-PUBIC OPERATION.[1]

BY F. S. WATSON, M.D.,

Surgeon to Out-Patients, Boston City Hospital, Surgeon of the Genito-Urinary Department, Boston Dispensary.

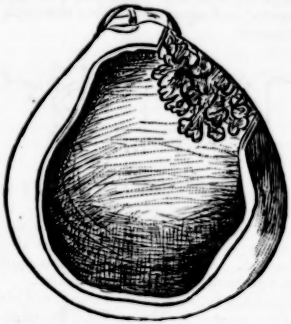
The patient whom I show here to-night, is a man of thirty-one years of age, who was referred to me by Dr. Forster, of Charlestown, early in July last. He had had several attacks of clap, from all of which he had made a complete recovery; with this exception had been entirely well up to seven months previously.

At that time, without provocation, he passed a good deal of blood with the urine, and pain attended the act; two months later he began to notice an increased frequency of micturition, and also observed some fleshy-looking bodies in the urine.

These symptoms, namely, hæmaturia, frequent urination, pain on passing water, and the passage of small fleshy bits, continued, with occasional remissions, up to the time I first saw him. The presence of blood and pain was not dependent upon exertion.

The patient steadily lost flesh and strength, and was going down hill fast. Examination showed the following condition: meatus, 21 (French). A No. 21 steel sound passed smoothly into the bladder. Search for stone was negative, nor did the sound meet with any abnormal obstruction.

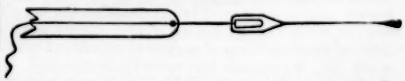
Rectal examination gave a prostate of normal size and consistency. The bladder wall was pliant and of normal character, except that just above the base of the right lobe of the prostate, there was a small area of increased resistance. There was no tenderness upon pressure above the pubes, and bi-manual palpation with one finger in the rectum and the other hand above the symphysis pubis, revealed nothing abnormal. The urine was drawn, and the bladder washed out with a large-eyed silver catheter. In the washings were several small fleshy-looking masses.



Examination by Dr. W. W. Gannett showed them to be very characteristic pieces of a papilloma.

The urine contained much blood and pus, a large number of epithelial cells, some of which had very large nuclei. The examination increased the hæmorrhage, but not seriously. The diagnosis was made of a sessile papilloma, situated on the floor of the bladder, immediately above the right lobe of the prostate, which was subsequently found to be the case.

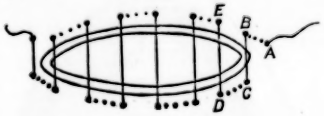
July 19th. The patient was etherized, Drs. Forster, Cabot, Tilden, Elliot, Cushing and Lovett being present. The supra-pubic operation was performed, after the manner recommended by Peterson, thus:



The bladder was emptied, and washed out with warm four per cent. boracic-acid solution, ten ounces of the same were left in the bladder. The pear-shaped balloon was then inserted into the rectum, and ten ounces of warm water were injected into it, dulness on percussion then became evident for about four finger's breadths above the symphysis pubis, but the bladder did not protrude forward.

The anterior surface of the viscus was then exposed by an incision through the linea alba. The peritoneal covering was *not* seen, a tenaculum was inserted into the bladder at the upper angle of the wound to steady it, and it was then freely incised in its long axis. The growth was found exactly where it was expected, a sessile papilloma, for the most part not much raised above the surface, having two longer branches however, and covering a surface of the mucous membrane about one and a half inches by half an inch. (Its situation and character, are approximately shown in the accompanying diagram.) It was removed by the finger-nail and a curette, and bled very freely.

An attempt was made to get a good view of the bladder by means of the electric light. But it was of no use for this purpose, the growth being at the bottom of a deep pocket which was constantly filled with blood.



Before removing all the growth, perineal section was performed for the sake of ultimate drainage, and in order to keep a constant current of hot boric solution passing through the bladder and out over the pubes to wash away clots and keep the wounds clean. This step greatly aided us in the rest of the operation. The perineal opening was made by passing a large steel sound through the vesical neck, *from within*, lodging its point in the membraneous urethra, and then cutting down upon this from the perineum. The wound thus made was small, only just large enough to admit a No. 29 (French) large-eyed catheter, which was passed through the wound into the bladder in the manner recently recommended by Dr. Keyes, of New York; namely, by threading the catheter upon a knotted string which passes through the closed end of the instrument, against the inner surface of which the knot catches. This end of the thread is then tied to a probe which is passed through the wound into the bladder, and the catheter is drawn after it. The thread being then cut between the probe and the catheter end, is withdrawn by the end which hangs from the mouth of the instrument.

The wound in the bladder was then sutured, Dr. H. W. Cushing's continuous intestinal stitch being employed, and fine black sewing silk used. The ellipse represents the bladder wound: the suture begins at the right hand angle and ends at the left. The

[1] Reported to the Society for Medical Improvement, Oct. 10, 1887.

dotted lines represent the course of the stitch parallel to the long axis of the wound, running between the outer and inner wall of the bladder just above the mucous membrane, taken a short distance from the border of the cut surface, entering for example at *A*, going beneath the surface to *B*, crossing the wound to *C* again, penetrating the muscular layer at *C* to pass to *D*, across the wound again to *E*, and so on. When drawn tight the edges of the wound are slightly inverted and the suture buried out of sight. This suture is the neatest and most satisfactory one with which I am acquainted.

After its application, the bladder was filled to test its efficacy and found perfectly tight. The outer wound was then united by deep sutures, except at the lower angle into which two rubber drainage-tubes were inserted. Antiseptic dressing was applied and antiseptic precautions pursued throughout.

Hæmorrhage into the bladder continued during the day of the operation. The perineal drainage-catheter did not drain a drop of blood or urine through it. Vesical tenesmus was exceedingly severe during several hours succeeding the recovery from ether, the bladder straining to force out the clots which were too large and dense to issue through the catheter and urethra. Morphia failed to relieve this symptom, and in the evening the perineal drainage-tube was removed. The tenesmus was relieved, but did not cease for two days. As a consequence, a portion of the bladder suture gave way, allowing the escape of urine by the pubis. Tenesmus ceased entirely after this, and the patient was much more comfortable. Six days after the operation blood ceased to appear in the urine, and there has been none since.

In the hope of hastening the closure of the bladder-wound a catheter, *à demeure*, was placed in the bladder through the urethra. No urine passed after this by the wound so long as the catheter, which was changed daily, was in the bladder, and the wound closed rapidly. A severe cystitis, however, came on, due, I think, to the presence of the catheter, and it was removed at the end of ten days. A fistulous tract persisted in the upper wound after this until September 12th, when it closed entirely, at the end of seven weeks and a half from the date of operation. Its healing was, I think, hastened by the use of iodoform pencils. The bladder was irrigated twice daily during the larger part of the patient's convalescence with warm boric four per cent. solution, which though not so strong an antiseptic as some others in use has become, owing to its unirritating qualities, the favorite bladder wash. Under the use of this remedy and the internal administration of acetate of potash and sandal-wood oil, the cystitis has entirely disappeared, and the function of the patient's bladder is now perfectly normal; he can hold ten ounces of urine without the least discomfort, and urinates only once in four or five hours, and entirely without pain or annoyance. The perineal wound healed in a few days. The patient is now absolutely well, in every respect; he has gained fifteen pounds of flesh, and says he never felt better in his life.

This case is one of a class which, but a few years ago our best authorities would have pronounced hopeless, and allowed to die without interference. The fact that instead of such an outlook, we can from time to time, not only save the life of such patients, but as in the case here shown restore them to entire health and comfort, marks one of the most notable advances of modern surgery.

I do not propose to go into the subject of tumors of the bladder here, at all exhaustively, but simply to use this case as a text in outlining some of the main points in connection with this interesting subject. There is reason to believe, in spite of the free discussions and frequent careful reports of such cases as this, that many are still overlooked; whenever one is dealing with a case in which hæmaturia is a prominent symptom, too much care cannot be taken to discriminate carefully as to its source in the genito-urinary tract (by no means an easy task in many instances.)

The main characteristics of hæmorrhage arising from a growth in the bladder, are, that it is independent of exertion, frequently being most marked when the patient is at rest. The blood is usually fresh. If a catheter be passed the first jet flowing through it is apt to be bloody. If co-existant renal disease be absent, shown by the absence of casts, (through bodies closely resembling blood-casts are sometimes seen in the urine when the disease is limited to the bladder), if stone be absent, and if there are found associated with the blood in the urine many polymorphous cells, with large nuclei, the presumption is that there is a new growth in the bladder. If, in addition, by washing the bladder, or by movements of the catheter, bits of the tumor can be found, the diagnosis is of course, certain.

If the patient be elderly, the chances are that the disease is cancerous; if young, a benign papilloma is the probability. In the former class the prognosis is necessarily bad as to life, in the latter fairly good, if properly treated.

The diagnosis once established, we enter upon a much more debatable ground in considering the operative measures for the relief of the disease.

All surgeons agree that the removal of benign growths should be attempted. The division of opinion comes in cases of cancerous growths. Sir Henry Thompson who has had a larger experience in this class of cases than any one else, refuses to operate upon cancerous cases at all. Guyon, and other French surgeons' experience, on the other hand, has been confined chiefly to cancerous growths, upon which they have operated as a measure of relief.

My first case of this kind which resulted fatally from an extension of the disease, about three months after operation, and which I reported to this Society about four years since, was one of primary cancer of the bladder; the patient had had great suffering from attacks of retention, vesical tenesmus, and frequent and painful urination. The operation I then performed was a perineal section, scraping away with a currette all the villous surface of the growth I could, giving a thorough stretching to the vesical orifice and perineal drainage.

The result was a cessation of the hæmorrhage and great comfort to the patient for several weeks preceding his death. And in studying the results of

similar cases in the hands of other practitioners, I find that relief has followed operative treatment in the majority of instances. This, it seems to me decides the question without further debate, and I cannot see any reason for refusing to operate, to drain the bladder at any rate, even in cancerous disease.

Having decided to interfere, what operation shall we choose? The choice lies between the perineal route to the bladder and the supra-pubic. Here again we meet with a division of opinion. Thompson, who originated and practised the digital exploration of the bladder, advocates always making such an exploration through the perineum at any rate as a previous step, to find out what is before the operator, and is then governed according to circumstances. If, for example, he finds a broad-based large tumor, he relinquishes the attempt to extract it by the perineal opening, and proceeds to its removal by the supra-pubic method, which, he thinks, can be equally well done after the preliminary operation.

If he finds a pedunculated or a friable sessile growth of a benign nature he proceeds to remove it by blunt biting forceps or a curette, or his finger-nail, at once through the perineal wound.

Guyon and the French and German surgeons for the most part reject entirely the perineal operation, and practice the supra-pubic method. The chief claim put forth by the advocates of this procedure is that it gives a clear field of view for the operation, and that you can see as well as feel what you are about, and that there is more room to work in.

The latter operation was practically recreated by Peterson, who, in 1881, showed that by filling the bladder with from 400 to 600 cubic centimeters of fluid, and injecting the same quantity into a pear-shaped colpeurynter placed in the rectum, the bladder is raised and carried forward against the abdominal wall, in such a way that it is much easier of access above the pubes, and more especially that its anterior surface, so apposed, is free from peritoneum to the extent of from two to four finger breadths, thus avoiding what had always been considered one of the great dangers of the operation; namely, the wounding of the peritoneum. Under these conditions the operation sprang again into great popularity, and has, it seems to me, been carried somewhat too far, especially in dealing with stone. The best record of mortality it can show in the hands of skilful operators is about 14 per cent.

Two further questions are to be considered in the performance of the supra-pubic operation. Should the bladder be sewed up, after the removal of the growth or should it not, and should perineal section for purposes of drainage of the bladder be done as a supplementary operation or should a catheter be left in the bladder and urethra without perineal section?

The former question is a very interesting one, but involves a longer discussion than can be entered upon here. I will only outline a few of the main points concerning it.

The Frenchmen, for the most part, leave the bladder and outer wound open, and either let the urine drain as it will through the wound until healed, or place long, double drainage-tubes in the bottom of the bladder, and carry them out over the pubes, in the hope of their acting as a syphon, frequently, also, placing a catheter, *à demeure*, in the bladder through the urethra. It may be said here that neither the double drains nor the catheter, no matter of what size or shape, or how placed, will effectually prevent the urine from running over the edges of the wound and surrounding tissues, and that, so far as avoiding contact of the urine with the wound, the tubes are practically useless.

Among the Germans, we find the strongest advocates of the bladder-suture. Into the various methods of applying, which I will not now enter, but merely mention that the number of cases in which the suture has been applied is about sixty, and that about thirty per cent. of these have been successful; namely, have healed by first intention, and, even in such cases as the suture has given way, the ultimate recovery has not been prejudiced.

The decision as to whether you shall apply the suture or not depends, I think, upon what you have left behind in the bladder. My own case would make me very unwilling to sew up again where I had left a bleeding surface. I made a mistake, it is true, I think, in using no larger a perineal drainage-tube, but even that which *was* employed helped to excite vesical tenesmus, for this symptom was greatly relieved upon removing it. Moreover, I should think that the end of the tube, resting against the raw surface of the wound made by removing the growth, as it would do in an empty bladder, would cause renewed bleeding, and so keep up the accumulation of clots, which were also responsible, I think, for the vesical tenesmus, which, after the operation, was so great that I am confident that no suture could have resisted the strain, but must have given way, and, until it broke, the pain was excessive. Another consideration is the presence or absence of cystitis. Here, one is placed between two fires. The foul urine, making its escape through the wound, increases the chance of sepsis. On the other hand, a bladder which is the seat of cystitis is less likely to unite when sutured, and, moreover, the thorough drainage which the open wound gives is about the best treatment for the cystitis. Furthermore, the bladder can be kept fairly clean by irrigating it thoroughly, two or three times a day, with hot boracic solution.

The conclusions I should reach in regard to applying the suture would be these:

(1) Where hæmorrhage is going on, or likely to occur to any great degree after the operation, it is better not to sew up the bladder.

(2) Where neither cystitis nor hæmorrhage are present at the conclusion of the operation, always sew up.

(3) Where severe cystitis is present, the decision is doubtful. Further experience is needed to decide this point.

The great argument in favor of applying the suture is that, if successful, it greatly shortens the convalescence, and decreases the risks of that condition.

If the suture is to be applied, silk should be employed and left in the wound, and the stitches should be taken through the submucosa as nearly as possible, but carefully avoid putting them through the mucous membrane itself. Having dealt with some of the important features of the supra-pubic section, let us return to the original question of the choice between this and the perineal operation.

It has always seemed to me that Sir Henry Thompson had the best of the argument in the discussion which took place between him and Professor Guyon

on this subject, in advocating perineal section and the exploration of the bladder as a preliminary step for enlightenment in regard to the exact nature and location of the disease.

In the majority of cases, one cannot determine beforehand the extent and situation of the tumor, and often, not its exact nature. Perineal section is, in itself, not a dangerous operation, and, in case the tumor is of such a character that it cannot be removed, it leaves the patient (certainly when he has been the subject of painful urination) better off, on the chances, than he was before; and, if the tumor be of such a nature that it can be removed by the perineal opening, the patient has not been subjected to the more serious high operation. I think, however, exception should be made in the case of persons with hypertrophied prostates, for the possibility of reaching the bladder and working effectually in it is very doubtful.

The claim that one gets an open view of the field in supra-pubic cystotomy may sometimes be true, but I cannot conceive that this should be the case where bleeding is going on from the tumor, for then the view must, as it was in my case, be entirely obscured. Moreover, if the growth be situated on the floor of the bladder, about the trigonum, the distance to it by the supra-pubic route is quite as great as by the perineal. I do not see how any general law can be laid down in regard to the best operation to be performed. The operator should be free from prejudice in regard to both, and ready to avail himself of either; but I can see no reason against his doing the perineal operation first, removing, by preference, from this point all such growths as are susceptible of being so treated; or, finding this impossible, to relinquish the effort, and proceed at once to the supra-pubic operation.

This brings us, naturally, to the consideration of the last point; namely, shall one do a perineal section as a supplementary operation to the supra-pubic for drainage? In my own case, the catheter failed wholly to drain the bladder, and was a source of pain as well. This, however, might have been different had I used a larger tube. But the question seems to turn more upon whether one intends to sew up the bladder wound or not. If yes, then a large perineal drainage-tube is the most efficacious means of keeping the viscus empty, and taking the strain off the stitches until healing is complete. It has seemed to me that this was a more certain means of accomplishing this end than by the ordinary catheter *à demeure*.

If the wound be left open, no further drainage is necessary, and the perineal opening is not called for.

CONGENITAL TALIPES EQUINO-VARUS.[1]

BY CHARLES L. SCUDDER.

A FACT REGARDING THE PATHOLOGY OF CONGENITAL TALIPES EQUINO-VARUS.

SCARPA and Little found no alteration in the form or position of the astragalus in congenital club-foot. Adams found a twist in the neck of the bone, but used no method to measure the twist. Parker and Shattock have found an inclination inward of the neck of the bone which is not constantly present.

I have examined five cases of congenital talipes equino-varus, and in every case have found a marked inclination inward of the neck of the astragalus.

To determine the obliquity of the neck of the astragalus, I used the method of Parker and Shattock, of London. The astragalus, with its trochlear surface upward, and resting upon a horizontal board, was placed beneath a fine, black-silk thread, fastened to stiff wire uprights by means of rubber elastics, the thread being half-way between the anterior and posterior extremities of the trochlear surface. A second thread was fixed to wire uprights at right angles to this first thread, and the astragalus moved until the second thread was mid-way between the lateral borders of the trochlear surface, and parallel with its inner border. A third thread, fastened at either end to wire uprights, was placed along the outer edge of the neck of the bone. The angle formed by the meeting of the second and third threads was taken, in each case, as the measure of the obliquity of the neck with the body of the bone. The angle was measured by a protractor of brass held firmly and horizontally over, and in close proximity to, the threads.

The bone presents three points of contact with the board, and, as each of these points is on the border of an articular surface, and, therefore, relatively constant, there can be little variation in the relative position of any two trochlear surfaces.

I have described thus at length the method used in determining the angle to be measured, for the slightest variation in position of the threads or bone alters the angle.

The mean angle of obliquity of twenty-three *adult* astralgi is 13.98°.
The maximum angle is 24.00°.
The minimum angle is 5.00° (measured).
Two bones, which evidently were from aged adults, showed the neck to be parallel with the body.
In three cases only was it found to be over 20°.
In two cases it was 19.66°; in one case 18.00°.
In two cases each it was 17°, 16°, 15°, 14°, 10°.
In three cases it was 13°. In one case each, it was 6° and 5°.
The mean angle of obliquity of eleven *fœtal* astralgi measures 33.52°.
The maximum angle measures 45.50°.
The minimum angle measures 17.50°.
The mean angle of obliquity of the necks of two *fœtal varus* astragali is 50.50°.

Taking the mean of these observations and those of Parker and Shattock, we find that:

The mean angle of obliquity in forty-three adult astralgi is 12.32°.
The mean angle of obliquity in twenty-two fœtal astragi is 35.76°.
The mean angle of obliquity in seven varus astragi is 56.05°.

Comparing the mean angles, it is at once seen that decided differences exist at the fœtal and adult extremes of life.

The angle of the obliquity of the neck of the astragalus with the body of the bone decreases with the advance in age from fœtal to adult life.

In two cases of evidently aged adult bones, the neck of the astragalus is parallel with the body of the bone.

It is interesting that this relationship between advancing age and different positions in parts of the astragalus suggests the variations in the angle which the neck and shaft of the femur undergo.

The obliquity of the neck of the astragalus is not constant for the same age within the main divisions, fœtal and adult; that is, astralgi from two different fœtuses, each seven months old, would not necessarily have necks of the same obliquity. In many of the fœtal specimens there was no varus, and yet a great degree of obliquity of the neck, almost as much, and, in some cases, more than is found in varus feet. The deformity, therefore, is not dependent alone upon the alteration of the neck of the astragalus.

[1] The Boylston Prize Paper of the Boylston Medical Society of Harvard University for the year 1887. Concluded from page 399.

Shattock and Parker mention a case in which there was marked deformity of the foot not easily corrected, in which case the angle of the neck with the body of the bone was less than the normal fœtal average.

I believe the change in the obliquity of the neck of the astragalus to be a part of the normal development of the bone.

Let *a b* of Figure 16 represent the body of a right astragalus, and *b c* the neck of the bone. Let the angle, *a b c*, be the mean fœtal angle of obliquity of the neck and body of the bone. If the bone develops *normally*, then we may suppose that the axis of the neck moves in the direction of the arrow, assuming positions varying with age.

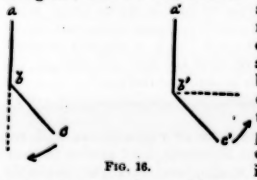


FIG. 16.

Let *a' b'* represent the body, and *b' c'* the neck of an astragalus of a right foot. Let the angle, *a' b' c'* be the mean fœtal angle of obliquity. If the bone develops to a *varus* deformity, then we may suppose the angle, *a' b' c'* to persist, or to change, according as the axis of the neck remains fixed, or moves in the direction of the arrow opposite to the direction of the arrow in the first figure.

The relation between the degree of obliquity and the age of the subject has not yet been established any more satisfactorily than the relation between the degree of rotation inward of the thighs and the varosity of the feet.

We know that in early fœtal life varus is physiological.

We know that, in very early fœtal life the thighs are often rotated outward.

We know that, in fœtal life, the varus foot presents a marked obliquity of the neck of the astragalus. In later life, all these conditions are different: the varus disappears, the thighs are usually not so much rotated out, the obliquity of the neck of the astragalus is greatly diminished.

The varus cases cited by Parker and Shattock, in which the angle of obliquity was nearly 31°, against the healthy mean, in their cases, of 38°, and the varus mean, in their cases, of 49.60°, is a barrier to definite conclusions as to constancy in changes in the astragalus.

My conclusions are:

(1) The obliquity of the neck of the astragalus is greatest in cases of varus, less in normal, and least in adult feet.

(2) A change in the obliquity of the neck of the astragalus is a part of the development of that bone, whether it be in a normal or varus foot.

(3) In all probability, this obliquity of the neck of the astragalus offers greater resistance to the reduction of the deformity in cases of congenital varus or equino-varus past the first few years of life than has hitherto been supposed.

RETARDED ROTATION OF THE THIGH INWARD NOT YET PROVED TO BE THE CAUSE OF CONGENITAL TALIPES EQUINO-VARUS.

H. W. Berg, of New York, in a theory advanced a few years since, makes the relative position of the foot and leg to depend upon the absolute position of the thigh and leg.

He says, in substance, that in early fœtal life the extensor surfaces of the upper and lower limbs look dorsally, and eventually, rotation takes place in such a direction as to bring the extensor surface of the lower extremity forward, and that of the upper extremity backward. The cause of this rotation is unknown, but is supposed by some to be due to the phenomena of growth.

The rotation begins about the second month, is to a great extent accomplished by the fourth month, and is completed by the end of the fifth, or beginning of the sixth month.

In a healthy fœtus, but little of the outward rotation of the leg or of the varus of the foot remains after the end of the sixth month. The foot is so placed by the outward rotation of the thigh and flexion of the thigh upon the abdomen, and partial flexion of the leg on the thigh, that the intra-uterine pressure causes an equino-varus position to be assumed by the foot. Later, by inward rotation of the thigh, the positions of the thigh, leg and foot are so altered that the soles of the feet lie against the uterine walls, and the intra-uterine pressure is exerted directly upon them. "Thus is antagonized," by intra-uterine pressure favorably exerted, "the varus or equino-varus which existed hitherto."

Upon the completeness of the inward rotation depends the rectification of the early varus of the foot.

During embryonic life a varus deformity is present as long as the leg has not completed its inward rotation. Should this rotation never take place or be incomplete, the child will be born club-footed.

The physiological and pathological varus is seen, according to this theory, to be dependent upon the primary outward rotation of the thigh in early fœtal life.

This theory seems to me to be the old mechanical idea modified by the factor, retarded rotation. In the mechanical theory there is an *accidental* position of the fœtal parts. According to this theory, the position of the fœtal extremities is *determined* by the amount of inward rotation of the thighs.

Berg calls especial attention to the fact that he considers that no extraordinary amount of intra-uterine pressure is necessary to produce the deformity, its cause being not pressure, but a retarded rotation inward of the thighs. In another place he says most emphatically, that the cause of the deformity *is* pressure. The reader is left in doubt as to his meaning. From the context, I judge him to believe that some pressure is necessary, else how could a mere movement of rotation occurring at the hip-joint cause a deformity in the foot. It is yet unsettled whether or no any pressure is exerted by the uterus upon the fœtal body or any part thereof sufficient to cause deformity.

According to the theory, rotation outward of the thigh is always associated with a degree of varus or equino-varus, and a completed rotation inward is never found with a case of varus or equino-varus. In other words, every case of congenital equino-varus should present at birth an extremity rotated out, this rotation being proportioned to the degree of deformity.

Berg has examined specimens in the New York Hospital and Wood's Museums in New York city, and places on record eight cases which are to illustrate his theory. He finds a progressive change in

the position of the extremities corresponding to different periods of fœtal life.

Through the kindness of Dr. C. S. Minot, of the Harvard Medical School, I have been permitted to examine over sixty-nine fœtuses of different ages, found in his collection, and I have also examined a few found in the Wyman collection of the Boston Society of Natural History, and I have been unable to discover that close association of non-rotation inward of the thighs with varus or equino-varus that Berg insists upon.

To determine whether or no there is rotation of the thigh outward is not easy. I have determined it by the position of the patella and by the position of a plane perpendicular to the extensor surface of the thigh.

To determine whether or no varus exists is not always easy, for it may be mistaken for an inward rotation of the foot dependent upon rotation out of the thigh and bending of the lower end of the tibia in, with a turning in of the foot dependent upon no structural changes whatever.

With all the precautions possible, I have tabulated the following observations and have arranged the several specimens in groups according to age and length. These observations are upon sixty-nine of the best preserved of one hundred and sixty-one fœtuses. The age and length have not a truly constant ratio.

GROUP I.

In twelve fœtuses of an average age of six weeks, and an average length of .013 meter, I find that the extensor surface of the thighs looks outward and dorsally, that the lower extremities are at right angles with the long body axis, and in several cases are somewhat conformed to the body curve. There is in all the specimens of the age of about six weeks, a uniformity and a constancy in the position of the lower limbs.

GROUP II.

In thirty fœtuses of an average age of from two to three months, and an average length of .058 meter, sixteen cases present no varus whatever, and in fourteen of these sixteen cases a slight outward rotation of the thighs exists. Here, then, are illustrations of rotation outward with absence of varus.

In fourteen of the thirty cases a varus or equino-varus exists of either one or both feet, with a slight rotation outward of the thighs. Here the relation presented by Berg is preserved to a certain degree. It is a noticeable and interesting fact that the fourteen cases presenting varus average younger than the sixteen cases with no varus. This difference in age is a slight one.

GROUP III.

In a group of twenty fœtuses of average age of from four to five months, and of average length of .131 meter, there is no varus or equino-varus in seventeen cases, and of these, four show no rotation outward of the thigh and thirteen do show rotation outward of the thigh. Of the remaining three cases, two show a slight varus of one foot, that is, one, of the right foot with no outward rotation of right thigh but with a slight outward rotation of the left thigh; the other, of the right foot with no rotation outward of either thigh. The third case presents slight varus of both feet, with outward rotation of both thighs. We find, therefore, in fœtuses of approximately the same age: (1) Rotation of the thighs outward, with and without varus or equino-varus. (2) Non-rotation of the thighs outward, with and without varus or equino-varus.

GROUP IV.

In a group of seven fœtuses of average age of six or seven months, and of an average length of .155 meter, rotation outward is present in four cases to a slight extent. It is absent in three cases. Varus is present in the right foot of one in which there is no rotation outward. Varus is present in the left foot of a second, in which the left thigh is slightly rotated out. In the other five cases the feet are straight, rotation outward is seen in three of the five.

My conclusions from the above observations are as follows:

(1) The position of varus or equino-varus with rotation out of the thigh, is present in all twelve fœtuses of average age of six weeks; and it is highly probable that up to six weeks the position of the fœtal lower extremity is constant and uniform.

(2) For the same age beyond six weeks the position of the feet is not constant.

(3) For the same age beyond six weeks the degree of rotation of the thighs inward is not constant.

(4) Rotation of the thighs outward is a quite constant phenomenon, occurring in fifty-one of sixty-nine cases in both legs, and of the remaining eighteen cases, eight rotated out one thigh, and not the other, and ten rotated out neither thigh.

(5) The cases showing no rotation were, as a rule, older than the cases presenting outward rotation.

(6) There is probably no necessary connection after the sixth week of fœtal life between the age of the fœtus, the rotation of the thighs, and the position of the feet.

(7) Most, although not all, of the varus feet, were found among fœtuses of from sixty to ninety days old.

(8) In group II, all the feet are varus; in group III, less than half of the feet are varus; in group IV, three of the twenty cases are varus; in group V, a single foot in two cases is varus.

As the age increases the varosity, if I may be allowed the expression, decreases.

In support of the theory of retarded rotation, Berg makes a summary of five points. Only two of these concern us now. He says first, "We have the fact that the leg is rotated outward in all cases born with this deformity and the tibia is bent inward at its lower part." I have carefully examined all the cases of varus or equino-varus occurring in the new-born that have been brought for some time to the surgical clinic of the Children's Hospital, Boston, Mass., and have been unable to find in all cases, outward rotation of the thighs. These observations, when any doubt existed, and at all times, have been corroborated by the attending surgeons in the out-patient department of the hospital.

He says second, "We have the fact that during embryonic life a similar deformity is present as long as the leg has not yet completed its inward rotation." A glance at the remarks upon Groups I, II, III, IV, will conclusively prove that this statement, upon which the theory so greatly depends, is not a fair one.

I might state here that I have observed that cases do occur in which children are born with the thighs rotated outward but with no other deformity.

THE CLIMATE AND HEALTH OF SAVANNAH.

BY D. F. LINCOLN, M.D.

SAVANNAH is on the west bank of the river of the same name, about ten miles from its mouth. It is situated in a flat, sandy plain, originally covered with a growth of pines. The trees have been cleared for a mile or two from the city in each direction, leaving open fields, dotted here and there with huts, where "truck" is raised for the early New York market. The bluff on which the city stands is some thirty feet above the tide of the river, but slopes directly on both sides to low, mucky grounds, formerly cultivated in rice, and pestilential, but now drained, tilled, and grazed. This improvement has been of great benefit to the health of the place.

The streets are mostly of sand, with paved sidewalks. Pedestrianism is not altogether attractive over such ground, or across the blank waste which immediately surrounds the city; nor is that form of exercise favored by the influences of the climate during the greater part of the year. A good horse is the best means for visiting the points of rural interest which lie among the woods, and on the banks of various tide-ways, at distances of two or more miles from town. Shooting is also very good sport, in the winter, among the low grounds all about. Savannah has a capacity for pleasing the Northern visitor greater than it is generally credited with. The obstacle to its enjoyment lies in the preoccupation of the traveller's mind with Florida. Unfortunately, it must also be added that the appliances for comfort necessary at Savannah, as well as in Boston, are not provided by the existing hotels, which may be briefly said to be rather less expensive than New York houses, but dear at the price. Florida has great advantages in that point, but Florida has been colonized from the North, and Savannah has not. It is all the more interesting to see a genuine, thoroughly Southern city, and Savannah offers one of the best specimens of its class.

A person flitting from the North, and spending a day or two on the way at Savannah, needs no special advice from me. For one contemplating several months' residence, it may not be out of place to be told that, on arrival at the end of October, one must not expect to be struck with the beauty of Nature in her mood of fatigue after the heats of six months, but must reserve a decided opinion until he has seen the real beauties of spring, opening towards the end of February, and growing steadily more remarkable for six or eight weeks, till the city is embowered in the foliage of trees and the blossoms of flowers. When it has grown most perfectly beautiful, you begin to think of going North, unless you are very fond of heat. Whatever else they may lack, the people of Savannah have a *real* spring, with many an hour of delicious, genial, soothing, sunshiny weather.

The entire season, for Northerners who wish to escape climatic dangers, is comprised between November 1st and June 1st. Summer weather, as understood at the North, is fully developed before May; it was splendid July weather, last April, in the third week.

For the purpose of giving distinctness to statements, I shall assume that the reader is chiefly interested, as regards climate, in a comparison between Savannah and New York or Boston. The mean temperature of the places may be compared in the following table:[1]

	Spring.	Summer.	Autumn.	Winter.
Boston	43.7°	69.3°	49.7°	28.3°
New York . . .	46.4	71.2	53.9	30.5
Savannah . . .	65.8	82.1	68.1	55.
Difference, B. and S.	22.1	12.8	18.4	26.7

The temperature of the year, as a whole (based on twelve years' observation, ending 1883), is, for Boston, 48.3°; for New York, 51.2°; and for Savannah, 66.9°, making Savannah 18.6° warmer than Boston on an average for the year.

It is well known that the measured temperature in Northern cities, in the hottest weather, is often nearly as high as in the South. The maxima observed (down to 1883) by the Signal Service were, in Boston: July, 101°; August, 96.8°; New York: July, 99; August, 96°; Savannah: July, 105°; August, 100°. But, in Savannah, the heat is much more equably maintained; it gives one no relief for several months. With us, on the contrary, the three summer months are those which present the greatest mean daily range.

Winter at Savannah causes a suspension of vegetation. The grass turns brown, the fields look bleak, the oaks, maples, cypresses, and other deciduous trees shed their foliage; even the evergreens are below their normal standard of color. Water rarely freezes. One may spend several winters without seeing a particle of snow. The severe cold of January, 1886, when ice formed several inches thick, and people skated on the canal, was very exceptional. The lowest temperature observed by the Signal Service is 16°.

The mere absence of severe cold is not so distinct a gain as it might seem, when considered by itself. But when we consider how large a part of our discomfort arises from sudden changes of weather, combined with wintry temperature, we may see wherein Savannah has the advantage. Both places suffer from changes of temperature in winter. The mean daily range is 17.6° for Boston, 16.8° for Savannah; but this change does not there involve our frightful alternations of snow and slush, ice and thaw. As soon, almost, as rain is over, the streets are dry enough for thick shoes. A transient guest *may* encounter a week or ten days of rainy weather; but, as a rule, the number of bad days is not great, and, when the rain does stop, the sun comes out bright at once. A stove in the hall is

[1] For the year 1882. Report of Chief Signal Officer, 1884.

as necessary there as here; but they have not found that out.

All our Atlantic climates are variable in winter and spring, and that of Savannah forms no exception, though the variations are less, and less frequent, than they are here. Most of the "cold waves" reach that part of the country, and affect the weather in a marked way. During the past winter, which was not an exceptional one, the temperature at Savannah rose and fell, with an approach to a weekly cycle; a day or two of warmish weather, calling for open windows or even doors, would be succeeded by a continued fall of the thermometer for two or three days, after which warmer weather would return. Many of the changes to cold come more suddenly than this. I have often seen it bright, warm, even sultry, all day, until in the middle of the afternoon the sky becomes threatening and squally, the wind changes rapidly to the west and north-west, clouds of dust arise, and the temperature falls 20° or 30° before nine o'clock. The signal officer told me he had observed one fall (on February 4, 1887) of 20° in *five minutes* under similar circumstances. These changes are predicted by the weather signals, and delicate persons ought not to go out while they are threatened.

Clothing should consist of thick autumn outer garments with medium or thick flannels. The inhabitants retain their winter clothing, in spite of its discomforts, until the first of May or even June, when the weather becomes free from these great fluctuations and takes the uniform heat characteristic of their summer. Strangers are warned that by making premature changes they run a risk of pneumonia.

The vicinity of the ocean and the river give a character of dampness to the air in winter. I have repeatedly sniffed the genuine flavor of a Massachusetts Bay northeaster.

There are rainy spells here, as elsewhere, and in winter there may be even a rainy week or ten days. One can often see the dampness in the form of a light fog, before breakfast; a heavy dew is another frequent occurrence. The general impression conveyed to the feeling is one of relaxation, rather than of bracing dryness. A man of great experience in the matter of horses informed me that these animals, when brought down from the upper country, were quite subject to "pneumonia," which may mean, however, bronchitis, until they get acclimated to the place.

It would be rash to extend a general invitation to bronchial patients to visit Savannah. That benefit may be gained, is true; it may be ascribed to the greater freedom of exercise in the open air (on horseback), to the frequency of open windows, and to the relief from the tax on vitality which low temperatures make. Savannah is not, however, a place where one can sit out of doors in the winter and enjoy it. One serious drawback must be mentioned; there are not a few days when the dust is a great annoyance. The streets are not generally paved or watered, and the result is equally discouraging to pedestrians and those in carriages; on horseback one is just enough lifted to be above the clouds.

One impression was strongly received during the six months of my residence. The "sunny south" is rightly so called. The sky is rather more brilliant than our clear skies; the lustre of the stars is more striking, and there is a great deal of sunshine. The sunny side of the house is the one recommended by experienced persons for residence, whether in winter or summer. In the latter season it is said that the prevalence of south winds makes that exposure the more agreeable in point of temperature.

The water-supply for the city is pumped from the river at a point two miles above, but owing to the rapid tide which sweeps past that point, it might nearly as well be below the city, for a part of the time at least. The water is brown, and after heavy rains deposits a sediment. It is said that seamen consider it a very desirable water, as it does not spoil in the casks. In a few cases it seems to cause diarrhœa, but that is not a characteristic effect. At the present time operations are going on to supply the pumps with artesian water of good quality.

Large use is still made of water from town pumps, which cannot be considered as fit to drink. The introduction of sewers has not put an end to the use of numerous privies, which continue to pollute the soil. Typhoid fever, by last year's report, was not excessively prevalent; 22 deaths, or about 1 in 2000 population, which closely approaches the rates in Massachusetts for 1883 and 1884. It is true that of the number of 95 deaths from "undefined" causation, a number may have occurred from typhoid.

The general rate of mortality at Savannah among whites is not such as to excite fear of special danger to health among visitors. Too much care cannot be given, however, to provision for comfort, if an invalid is in question. A delicate person, transferred from a well-warmed Northern home to the comparatively comfortless arrangements found in a Savannah hotel, or in many boarding-houses, incurs a certain risk to be considered and provided against.

PRINCIPAL DISEASES.

The table which is here given is selected and calculated from the "Tabulated Mortuary Record of the City of Savannah from January 1, 1854 to December 31, 1869," by Dr. W. Duncan; and from Table X, of the Massachusetts Forty-fourth Registration Report, giving data for forty-four years, eight months, ending December 31, 1885.

NUMBER OF DEATHS IN EVERY 1,000, FROM CERTAIN CAUSES.

	Mass. 44 years.	Savannah 16 years.	
		White.	Colored.
Yellow Fever	....	88	3
Malarial Fever	.9	123	62
Typhoid Fever	41.5	39	43
Small Pox	5.0	3	1.6
Dysentery	29 4	32	29
Diarrhœa	12.4	37	43
Cholera Infantum	48.1	11	9
Enteritis	11.6	18	17
Phthisis	181.6	79	75
Dropsy	16.4	21	49
Cancer	17.7	5	8
Paralysis and Apoplexy	35.2	12	15
Cephalitis	22.0	35	28
Convulsions	47.2	95	105
Other Nervous and Brain disorders	20.6	14	12
Trismus Nascentium	...	18	36
Teething	9.7	24	29
Pneumonia	63.5	52	83
Miasmatic Diseases	255.4	419	292
Diathetic Diseases	42.9	28	61
Tuberculous Diseases	215 1	102	97
Nervous Diseases	96.0	154	157
Diseases of Circulation	39.2	11	16
Diseases of Respiration	83.9	73	117
Diseases of Digestion	39.6	49	48

Dr. Duncan's figures include the period of the

Civil War, which has doubtless caused some loss of accuracy; for example, there are 408 cases of death from "cause undefined" for 1865. In estimating rates I have subtracted the 776 "undefined" from the total of 9,445, leaving 8,669 as a basis for percentages; the same was done in the Massachusetts report.

In drawing conclusions from this table, we may, it is hoped, omit yellow fever from our calculations for the future. With this exception, we find that the two leading causes of mortality among whites in Savannah have been *malarial fevers* (1,071 deaths), and *convulsions* (805 deaths). This result is so widely different from that in Massachusetts, that we may set these two diseases aside, before trying to compare the two districts in other respects. (It is proper here to notice the prevalence of the convulsive affection *trismus nascentium* at Savannah, whereas it is not separately named in the Massachusetts report).

After the above, follow two diseases which represent the two leading causes of death among whites in both sections; *consumption* and *pneumonia*. The comparatively small amount of consumptive disease in Savannah is one of the most prominent facts in the Table. The addition of the following eight, completes a list of the ten most fatal diseases at Savannah; namely, *typhoid fever, cephalitis, diarrhœa, dysentery, teething, dropsy, enteritis*, and *trismus nascentium*. With this list may be compared the following eight in Massachusetts: *cholera infantum, typhoid fever, heart diseases, scarlatina, dysentery, diphtheria, cephalitis*, and *paralysis*.

In reckoning mortality from typhoid, I have added in a few cases of typhus and continued fever, to bring the Savannah data parallel with those of Massachusetts. Similarly, I have added together meningitis, eucephalitis, and congestion, to procure data corresponding to the Massachusetts "cephalitis."

On the whole, the Southern city presents a very high mortality from nervous diseases and miasmatic fevers, and a rather high rate from digestive disorders: the Northern State suffers greatly from tuberculosis, has rather more local respiratory disease, and is distinctively marked by a relative excess of circulatory and diathetic diseases (except dropsy). The Northern type of disease perhaps tends to chronicity and slow degeneration: while the Southern is more marked by acuteness, and febrile action. Phthisis, cancer, paralysis, and apoplexy, exhibit certain common points of the former type. Bright's disease, however, is named as causing a good many (14) deaths in the year 1886, at Savannah.

Typhoid fever has already been mentioned. There exists in Savannah a very common fever, of mild type, rarely causing death, to which the name of "continued fever" is applied. It is apparently a typhoid, without the specific traits of the latter. No autopsies can be cited. Dr. Duncan makes the following statements to me: "From a long experience with this fever, I am satisfied that it is *not* a true typhoid, though it belongs to that class of fevers. In the continued fever there is no diarrhœa or dysentery, nor tympanites, but on the contrary the bowels are generally constipated; there are no rose-colored spots, and the tongue may be, and often is, perfectly clean; there is no subsultus; death, when it occurs, is generally from a relapse and *from exhaustion*, never hæmorrhage of any kind; and there is no delirium until near the end. . . . The continued fever generally runs its course in about twenty-one days, and does not leave the subject so prostrated as typhoid. . . . In my experience, any error of diet will bring on a return of the fever, and it is very important to impress on the attendant the utmost caution. I have seen quite a number of cases where the only symptom was the regular rise and fall of the fever for three weeks and sometimes even more, and not another bad symptom of any kind. In my judgment it is closely allied to typhoid, and may arise most probably from some defect in sewers, etc. I think it has been traced to that source in several cases this season. It is clearly not a malarial fever, and quinine will not influence it as it will a true malarial fever."

In the report of the City Physician, Dr. McDougall, for 1886, the total number of deaths among whites, is given at 452. All of the twelve causes first enumerated are prominent except dysentery, and of course yellow fever. Heart disease, marasmus, measles, and paralysis, are also prominent. There are thirteen "undefined." The most interesting fact in the Table is the diminished number of deaths from malarial fevers.

Under the heads of congestive (16), remittent (16), and typho-malarial (4), the total mortality from malarial fevers was thirty-six, making eight per cent. of the whole number of deaths. This is a reduction of over one-third from the former average, and doubtless indicates a permanent improvement.

It is important to know whether the climate of Savannah is unfavorable to the development of consumption. It does not possess the advantages of the best typical climates, height and dryness. But the statistics seem to show that the native inhabitants, (including under this term the whites born in Georgia, the Carolinas, and Florida), are by no means largely subject to this disease. This class, in fact, furnishes only 232 deaths out of 692 that occurred in 1854 to 1869. The following table is abridged from Duncan:

DEATHS AMONG WHITES FROM CONSUMPTION, 1854-69, BY NATIONALITIES.

Birthplace.	
Georgia	178
The Carolinas and Florida	54
Mississippi and Tennessee	2
Distant States (Me., N. H., Vt., Mass., Conn., N. Y., N. J., Penn., Mo., O., Ky., Md., Va.), and Provinces (Can., N. B., N. S.)	81
Ireland	264
England and Scotland	27
Germany	31
Other Countries	24
Unknown	31
Total	692

The large mortality among native Irish cannot be accounted for by unfavorable surroundings, for they are fairly prosperous in Savannah. They can hardly, at present, exceed one-fourth of the white population, while their rates from consumption are about thirty-eight per cent. of the whole number dying of that disease.

MORTALITY AMONG THE COLORED POPULATION.

The blacks and mixed population form a little more than two-fifths (⅔) of the inhabitants of Savannah — 19,111 out of 45,786, according to the census of 1885–86. The mortality among them was, in 1886, 49 per mille; among the whites, 17 per mille. A similar high rate is shown in the returns from elsewhere; for example, in 1884, among a combined population in Southern cities of 656,603, the rate of whites was

21.5, for the colored 36.6.[2] The rates fluctuate a good deal, but this may be corrected by comparing groups of years. For example, during the eight years, 1854–61, the yearly colored mortality in Savannah ranged from 24.8 to 34.3, which is better than that of the whites, which varied from 29 to 97.9. If we take the ten years, 1877–86, for comparison, we find a complete reversal of things, for, during these years, the colored rates ranged from 35.4 to 58.8, and those of the whites from 13.7 to 29.1.

The improved drainage and water-supply of the city have doubtless contributed to the present low rate among the whites. Why have they not benefited the colored people?

Among the facts which appear unfavorable to the blacks, we can point to the excessive number of deaths from lung diseases, the large mortality among children, and the evidence of great neglect or poverty, as characteristic of their lives.

Pneumonia, bronchitis, catarrh, pleurisy, hydrothorax, asthma, and consumption form a group which, in Dr. Duncan's statistics, are seen to have been very fatal to the colored race, even in the times before the war. At the present time, the case is much worse. The following are the data for 1886:

	Deaths, Actual.		Deaths which should have occurred among colored population, based on white rates.
	Whites.	Colored.	
Consumption	49	107	32
Pneumonia	16	74	10
Congestion of the Lungs	13	13	9
Bronchitis	4	22	2
	82	216	53

A comparison of the second with the third column of this table shows that the colored race suffers four times as much as the whites from the principal lung diseases.

During 1886, the colored people suffered much from malarial fevers and diarrhœa. Among the children, teething and trismus were very fatal. The deaths under the age of two years numbered 35 per cent. of all deaths; among the whites, 30 per cent. It should be added that there were 19 still-births among the whites, and 144 among the colored, not included in the number of deaths. This indicates a state of morals which one might expect to find associated with physical misery, as, in fact, it is.

Another significant fact is the number of colored people (244) that died in 1886 without having a physician in attendance, the corresponding number of whites being only 14. Whether this be due to poverty, ignorance, superstition, or carelessness, it certainly suggests a wretched and helpless condition of life. Special liability to lung diseases seems to exist among them, but this does not fully account for their enormous death-rate.

In preparing the statistics for this paper, I have used those of the white race for the purpose of comparison with those of Massachusetts. If I were comparing them with those of a great metropolitan city, the propriety of thus excluding the colored race would be doubtful, for New York possesses a large class of poor, whose manner of living places them on a parallel with the negroes, and who equally deserve to be excluded from statistics representing the self-helping classes of the population. In both cases, there exists what Dr. McDougall (of Savannah) calls "an incubus population," incapable of properly caring for themselves, and constituting a grave responsibility for their abler neighbors.

Something, in conclusion, may now be said in the way of general advice to those contemplating a journey. It is always well to bear in mind, while planning the trip, that there is a great change to be undergone. Leaving New York or Boston in October or early November, we give up a bracing, brilliant climate for a moist, relaxing one, and must expect rather a depression of energy. Going in mid-winter, we can but be thankful for an escape from many trials, and for a sight of even a moderate amount of verdure. Going in February, we may expect a new experience — the joys of existence in spring-time — but, in returning, it may be well to anticipate something of a shock. A passenger leaving Savannah near the end of April, and sailing direct for Boston, may find that he has leaped three months back towards winter — a change which, for delicate persons, must be broken by repeated rests at such intervening stations as Charleston, Norfolk, and Bethlehem. The old rule was "to follow the strawberries North."

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M.D.

THE LENGTH OF THE FINGERS AND THE MOVEMENTS OF THE WRIST.

PROFESSOR BRAUNE and Dr. Fischer have written an admirable paper on the mechanics of the human hand, which is shortly to appear in the Proceedings of the Royal Society of Sciences of Saxony. In the meantime, Professor Braune has given an abstract of the paper before the Anatomical Society of Germany,[1] and the part on the length of the fingers has appeared elsewhere.[2] The results of the measurements of the fingers are not in accord with those hitherto accepted, made, we believe, by measurements from the living or undissected hand. Thus Mantegazza found, in seven hundred and twelve cases, that the ring finger was longer than the index in five hundred and eighty-nine, and shorter in ninety-one.

Braune and Fischer point out some of the causes of fallacies in measurements of the fingers on the living. In the adult, the phalanges of the four fingers are not in line with their metacarpals, but are bent towards the ulnar side. The forefinger can be brought towards the thumb only enough to bring it into line. If we place it thus, and bring the other fingers against it, the apparent relative length of the fingers is strikingly changed. In these studies, the length of the metacarpal bone is measured from the middle of the base. The observations were made on forty ligamentous preparations. To avoid error from abduction or adduction of the fingers, the relative lengths of the index and ring fingers was taken by connecting by a straight line the middle points of the bases of the metacarpals, and measuring the fingers along straight

[1] Anatomischer Anzeiger, 1887, No. 12.
[2] Archiv. für Anatomie und Entwickelungsgeschichte, 1887.

lines drawn perpendicularly to this one. In twenty-six cases, the system of the index (all included) was longer than that of the ring finger; in ten cases the ring finger was longer, and in four they were equal. The order of the metacarpal bones, arranged according to length, is the second, third, fourth, fifth, first. Twice the third surpassed the second by trifling quantities, and three times they were equal. The systems of the phalanges of the several fingers are as follows, in the order of length: third, fourth, second, fifth, first, which shows that the greater length of the index, compared to the ring finger, is due to the metacarpal. The relative length of the proximal and middle phalanges respectively, is, with a few exceptions, the same as that of the entire phalangeal system. There are, moreover, measurements showing the part each bone contributes to the length of the finger, which is called 100.

	Metacarpus.	1st Phalanx.	2d Phalanx.	3d Phalanx
Thumb,	47	31	22	
Index,	44	27	17	12
Middle,	40	29	19	12
Ring,	38	29	20	13
Fifth,	42	27	16	15

This does not quite correspond to Langer's formula for the middle finger, in which the relative lengths of the bones are represented by eight, five, three, two, the metacarpal being equal to the first and second phalanges, and the first phalanx to the other two. Langer, however, measured the distance between the several axes of rotation of the joints.

In studying the movements of the wrist, the entire motion was first measured, and then an intermediate or neutral plane found to serve for a starting point. The motions of every point of bone firmly connected with the joints was found to be in concentric sections of a sphere, the centre of which is in the head of the *os magnum*.

It is well known that flexion and extension of the wrist occur in two joints, the first between the radius and the carpus, and the second between the two rows of carpal bones, but authorities differ as to the share of each joint. Braune and Fischer find that the radio-carpal joint is much more concerned in flexion than in extension, and somewhat more in bending the hand to the ulnar side than to the radial. In the intercarpal joint, extension was about three times as free as flexion and movement towards the radial side; rather greater than towards the ulna. They found, further, that if the three proximal carpal bones are fastened immovably together, so as to form but one, motion, especially extension, is much diminished in the intercarpal joint. Thus the motions of the hand take place around the head of the *os magnum*, which is embraced by two concentric sockets, each made of movable pieces, for not only is there motion between the separate bones of the first row, but the relations of the lower end of the radius, the triangular cartilage, and the end of the ulna change also. This is due to looseness at the elbow, allowing some change of relative position between the bones of the forearm.

THE MECHANICS OF CERTAIN MOVEMENTS OF THE FINGERS.

It is well known that if the middle phalanx of one finger be flexed on the first (it does not matter whether the latter be flexed on the metacarpal or not), the last phalanx is powerless. It may be bent or extended by the other hand, but cannot be moved in obedience to the will. Mr. Tuffier[3] has written a paper on this, which is interesting in several respects, though it does not contain much that is very new. A very important point is brought up incidentally; namely, the insertion of the common extensor of the fingers. In most works, it is described as inserted into the second and third phalanges. No notice is taken of its insertion into the first phalanx, though it is a very important point, and has been correctly described by Duchenne. Tuffier points out that, if the tendon be cut at the middle of the metacarpal bone, reflected and dissected from below, the insertion into the base of the first phalanx is evident. The writer of this report has been in the habit of demonstrating the point as follows: He divides the tendon at the middle of the first phalanx, cuts the lateral expansions, and reminds the class that, if the usual description be correct, the tendon should now be free, or held only by areolar tissue. He then shows that it can be torn loose from the first phalanx only by great violence. Tuffier points out that it is inserted, also, into the distal half of the capsule, so as to pull it out of the way of the joint. The continuation of the tendon is joined by fibres from the lumbricales and interossei, some of which arch over the dorsum of the first phalanx, while others join the lateral prolongations of the tendon which go to the last phalanx. When the second phalanx is flexed on the first, the expansion is drawn forward, the middle tendon to the base of the second phalanx is tense, while the lateral parts of the tendons just mentioned tend to slip off to the sides of the end of the first phalanx, and become relaxed. Tuffier ascribes to the tension of the middle tendon a subordinate share in the production of the flaccidity of the last phalanx, and we must own that we are unable to follow him.

He is undoubtedly right, however, in ascribing the chief share to the relaxation of the tendons that run to the last phalanx. He confirms this by a very neat experiment. The second phalanx being flexed on the first, a pin is passed under the tendons at the end of the former, so as to hinder the relaxation of the lateral parts, and it is then shown that the last joint is no longer loose. The reason why it cannot be actively flexed is much more simple. This depends on the interlacement of fibres in the different divisions of the deep flexor. If all the fingers of one hand be put in the described position, the want of power of extension of the last phalanges persists, but they can be actively flexed. This power is wanting only when one finger is so placed.

THE PALMAR FASCIA.[4]

Dr. Max Grapow has written a very detailed description of the palmar fascia, which is intended to determine with precision several smaller points. We shall allude merely to the deductions as to the uses of the fascia. First, it secures the arching of the skeleton of the hand, and resists its flattening under pressure. Second, it has an hydraulic action, and by its alternate stretching and relaxation drives the venous blood and lymph towards the heart. Third, it renders the grasp of the hand surer by its intimate adhesion to the skin. Otherwise the skin would fall away from the hand, as in the case with even the closest fitting glove.

THE SHEATHS OF THE TENDONS OF THE HAND AND WRIST.

This important subject has of late received much attention. Dr. Larger,[5] a few years ago described a new sheath connected with that of the tendons of the radial extensors. This new sheath is above the tendons at the place where they are crossed by the tendons of the extensor ossis metacarpi pollices and that of the extensor primi internodii; its describer calls it "la gaine antibrachiale."

Debièrre and Rochet[6] were induced by this paper to investigate the subject again. Their results by no means agree with those of Larger. Beneath the tendons of the extensors of the metacarpal bone and of the first phalanx of the thumb they found a serous bursa which Larger had mentioned as "accidental and professional," resulting, according to him, from twisting the hand on the arm. Debièrre and Rochet, however, found it in every one of forty extremities on the left as well as on the right, in women as well as in men, and in children as well as in adults. They accordingly considered it constant. This bursa having been opened, the radial extensors are seen beneath its deep wall, and the *gaine antibrachiale* should be found between them and it. These observers, however, never found it at all, and set it down as an artificial production. They find the synovial sheath of the two radial extensors, usually single but sometimes double. In the former case it always communicates with that of the extensor secundi internodii policis. When it is double, the sheath for the longer radial extensor is quite closed, but that of the shorter one communicates with the extensor of the second phalanx of the thumb. It would appear from this that there is a discrepancy between these authors and Gruber of St. Petersburg, who found that the sheath of the latter tendon communicated with that of the radials 149 times in 290 cases.

A very interesting and even more important paper is that by Dr. Alfons von Rosthorn[7] on the "Synovial Sheaths of the Flexor Tendons in the Palm of the Hand and in the Fingers." If he is right, and we must say that his paper is very convincing, the descriptions in our text-books are wrong in important respects. These, however, are by no means the same. For instance, in the tenth edition of "Gray," we find the following statement: "A synovial sheath invests the tendons as they pass beneath the annular ligaments; a prolongation from which surrounds each tendon as it passes along the phalanges." This, however, may be dismissed at once as behind the times. "Quain's Anatomy," ninth edition, is by no means up to its average in this matter. "The tendons of both the superficial and deep flexors, as well as the median nerve, are surrounded beneath the annular ligament by a large and loose synovial bursa, which extends upwards to the level of the radio-carpal articulation, and downwards to a little beyond the bases of the metacarpal bones, being prolonged further on the little finger than on the others. According to Max Schüller, this bursa is double, the sheath investing the two ulnar fingers being separated by a longitudinal partition from that of the index and middle finger tendons. The latter division communicates opposite the upper border of the annular ligament, by a small aperture, with the synovial sheath of the flexor longus pollicis tendon."

Tillaux's description is the one generally accepted. There are two sacs, one for the tendon of the flexor of the thumb which extends from the wrist to its insertion, the other encloses the flexors of all the other fingers extending to the end of the little finger, but stopping short of the other fingers, each of which has a separate sheath.

Von Rosthorn describes two chief sacs which are separated at the upper end by the median nerve. The radial one corresponds to Tillaux's description, but the ulnar one differs from it in essential points. It encloses only the tendons of the fourth and fifth fingers in the palm of the hand, and is usually continuous with the sheath of the tendons in the little finger, rarely with that of the ring finger. The second, third and usually the fourth fingers have separate sheaths opposite the phalanges, and the tendons of the index and middle finger have no synovial sheath in the palm. Another important fact which he has shown, is that in the young child, each of the five fingers has a separate synovial sheath of its own, and that the almost constant junction of that of the thumb with the radial sac and the usual junction of that of the little finger with the ulnar one are the results of secondary changes, not the primitive condition. Occasionally a third carpal sac is found between the other two. The more common arrangement of this additional sac is for it to be wedge-shaped with the base above and the point separating the other two for a short distance. It contains in this case no tendon. More rarely it completely separates the other two sacs and contains the tendon of the deep flexor of the index. The superficial tendons of the index and middle fingers may as an exception have independent sheaths of their own in the palm of the hand communicating neither with one another, nor with the carpal sacs, nor the phalangeal sheaths. That of the index is the more common, and von Rosthorn found it particularly well developed in the hands of robust workmen. The superficial tendons of the fourth and fifth fingers have frequently imperfect synovial sheaths in the palm of the hand inside the carpal synovial sac and communicating with it.

This writer gives much attention to the curious question of how these tendons, when inclosed in synovial sheaths, receive their vascular and nervous supplies. He finds an arrangement of synovial folds perfectly analogous to that of the mesentery. Some tendons, like that of the thumb, have a true fold, others project partly into the synovial cavity after the fashion of the descending colon. Sometimes, however, the long fold is interrupted and then the comparison no longer holds. The vessels, of course, reach the tendon on the reverse side of the synovial membrane. There are many points of detail for which we must refer the reader to the original.

A word on the methods employed may not be out of place. We can bear witness to the difficulty of making trustworthy injections of synovial sheaths; that is, such as shall exclude all suspicion of extravasations. Debièrre and Rochet often inflated the sheaths with a subcutaneous syringe which makes so small a hole that the air does not escape when the tube is withdrawn. This is a useful method for study, but one which will not give permanent results. They also used injections of mercury which seems to us one of the worst possible masses for the purpose.

[5] Revue de Chirurgie, 1882.
[6] Archives de Physiologie. Série III. Tome 3, 1887.
[7] Archiv. für Klinische Chirurgie. Band, xxxiv, 1887.

There are others that run as finely, are easier to manage and more durable when made. Von Rosthorn strongly recommends Teichmann's mass, which we believe is essentially sealing-wax dissolved in ether or other evaporating fluid. Some of his illustrations represent really beautiful injections. When the sheath is injected from the end of the finger there is often much difficulty in persuading the mass to run through the narrow passage, and it is useful to move the finger and rub it gently towards the palm. In the fingers whose sheaths do not join the carpal sacs, we gather that it is well to make a counter-opening for the escape of the synovia. Another method that gives less striking but valuable results is to distend the sheaths with tallow which is to be removed when they are hardened. Windows can then be cut where it is desired.

THE RELATION OF THE THYROID TO THE CEREBRAL CIRCULATION.

Professor Waldeyer[8] made some remarks on this point before the Berlin Medical Society, which though not wholly new, deserve mention. He gives Staël credit for having pointed out relations between the superior thyroid artery and the internal carotid. It is well known that the latter enters the skull through a canal that cannot be distended, however violent the heart's action may be, and also that the artery is very tortuous, thereby protecting the brain. The effect of both these arrangements is to make it probable that there is occasionally a certain "backing up" of the blood in the internal carotid, and this artery very frequently has a dilatation just at its origin, which, under such circumstances, would come into play. Staël has shown that when the superior thyroid (the first branch of the external carotid) is small, this bulb is large, and when it is large the bulb is wanting. It is therefore probable that the thyroid acts as a reservoir to receive an excess of blood passing through the carotids and subclavians. Waldeyer points out that precisely the same relations exist between the vertebral and the inferior thyroid arteries. This strikes us as rather a strong statement, but an analogy is evident. Comparative anatomy seems to support the theory of a relation between the circulation of the brain and that of the thyroid. Only in the apes do the vertebrals nearly equal the carotids. In lower mammals the vertebrals become less important and the carotids alone supply the brain. In the ox and the horse the occipital artery takes a part in the cerebral circulation. Now in the majority of mammals both the thyroid arteries come from the carotid; that is, from the artery supplying the brain. Waldeyer believes that he has found an arrangement in the thyroid, fitting it to receive sudden extra supplies of blood. The capillaries have numerous diverticula which allow them in case of need to expand into sponge-like structures.

THE PHARYNGEAL OPENING OF THE EUSTACHIAN TUBE.[9]

Casimir von Kostanecki has written an elaborate and very valuable paper on the eustachian tube and its relations, especially at the pharynx. Much of it is necessarily so technical that it seems unadvisable to attempt an abstract of it. One point to which we would call especial attention is the great individual variation of the arrangement of parts in the pharynx. The cartilage at the back of the opening presents many shapes and degrees of development, and on this, together with the thickness of the mucous membrane and the amount of adenoid tissue, depends the prominence of the fold between the orifice of the tube and the fossa of Rosenmüller. There are many admirable illustrations that show the various forms with a clearness that a description cannot have, and which will repay careful study. The author gives several measurements of the distance of the orifice of the tube from other points. First, the distance from the anterior nasal spine varies from 5.3 to 7.5 centimetres. Second, the distance from the level of the hard palate changes greatly during life. In the fœtus the opening is below the hard palate, at birth it is at about the same level, and in the adult on the average about one centimetre above it. Third, the average distance from the roof of the pharynx is about eleven or twelve millimetres. Naturally, the amount of adenoid tissue in the roof must affect this measurement considerably. Fourth, the distance from the posterior wall of the pharynx varies from the same cause. The mean is twelve millimetres. Fifth, the distance from the inferior turbinated bone is extremely variable, ranging in the adult from 4 to 14.5 millimetres. The cause of this is chiefly in the turbinate bone and in the thickness of its covering. Both the size and the shape of the opening are very uncertain.

THE STRUCTURE AND FUNCTION OF THE THYRO-ARYTENOID MUSCLE.

The relation of this muscle to the true vocal cord has not been determined beyond dispute. According to some, the muscle runs along the side of the fibrous tissue of the cord; according to others, the muscular fibres join the fibrous elements. Dr. Alexander Jacobson[10] has shown by series of horizontal and frontal microscopic sections that the latter view is the correct one, and that, accordingly, this muscle may separate the vocal cords, thus sharing with the posterior cricoarytenoid the honor of being an opener of the glottis.

THE MORPHOLOGY OF THE SACRAL PLEXUS IN MAN.

Dr. A. M. Paterson[11] has obtained some very interesting results by his dissections of this plexus. The generally received idea of its formation is that "the nerves unite without much interlacement into an upper large, and a lower small, cord or band." As a starting point, Dr. Paterson insists on the absence of connecting nerve-fibres between the two great branches of the great sciatic nerve, the external and internal popliteal nerves, which are entirely distinct. Sometimes, indeed, they arise independently from the plexus being separated by a part of the pyriformis muscle. Now the sacral plexus is formed by the anterior primary divisions of a part of the fourth and fifth lumbar nerves, the first three and a part of the fourth sacral nerves. The two popliteal nerves have a distinct and definite origin. The descending branch of the fourth lumbar nerve, and the following three nerves each and all divide into an anterior and a posterior branch. The anterior branches uniting form the internal popliteal, and the posterior branches the external popliteal. The former receives an additional branch from the third

[8] Deutsche Medizinal Zeitung, 1887, No. 22.
[9] Archiv. für Mikroskop. Anatomie. Bd. xxix.
[10] Archiv. für Mikroskop. Anatomie. Bd. xxix.
[11] Journal of Anatomy and Physiology, Vol. xxi, April, 1887.

lumbar. The small sciatic and the pudic nerve are associated at their origin. The two gluteal nerves each arise from posterior branches of the nerves that form the plexus and thus are associated with the external popliteal, while the nerves supplying the hamstrings are derived from the internal popliteal.

The two largest nerves of the lumbar plexus present striking analogies. The obturator and the anterior crural nerves are (as a rule) derived from the second, third, and fourth lumbar nerves, which divide into anterior and posterior parts. The anterior branches unite to form the obturator, and the posterior ones the anterior crural. A glance at the illustration in "Quain's Anatomy" will show this arrangement, though the fact that certain branches are anterior and others posterior is not mentioned in the text. Dr. Paterson goes on to show the areas of distribution of the nerves of the lower extremity. The front of the thigh, knee, leg and foot, together with the glutei and tensor vaginæ femoris are supplied by the anterior crural and the external popliteal nerves; that is to say, by those formed by the posterior branches, and these parts belong to the dorsal aspect of the bud, which in very early embryonic life is the precussor of the limb. The parts which come from its ventral surface, to wit, the back and inner side of the thigh, the back of the knee, leg, and the sole of the foot are supplied by the obturator and internal popliteal nerves which arise from the anterior or ventral branches.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

HERBERT L. BURRELL, M.D., SECRETARY, *pro tem.*

THE President, DR. O. F. WADSWORTH, in the Chair.

DR. J. C. WARREN reported a case of

GASTROSTOMY FOR THE RELIEF OF CANCER OF THE ŒSOPHAGUS.

A man, fifty-six years of age, presented himself at the Hospital, in the autumn of 1886. After attempts at keeping the stricture patent with probings had failed, the operation was performed January 1, 1887. The method of stitching the stomach to the abdominal wall was that known as House's method. The stomach was opened on the ninth day. The fistula, becoming enlarged, was kept closed by a valve-like apparatus, which effected the purpose tolerably well. The patient lived four months after the operation.

DR. M. H. RICHARDSON had seen Dr. Warren's case, and felt that operations of this description were only tentative, and were indicated where starvation is imminent. The indications are analogous to those for which we do colotomy for intestinal obstruction from malignant disease, or tracheotomy for malignant disease of the trachea or larynx. He believed that the double row of stitches took too long for their application, and considered that time was very important in all such operations. Dr Richardson considered the McCormick's method of the application of stitches all-sufficient. Regarding the immediate opening of the stomach, it had the advantage of at once relieving the urgency of the symptoms, and he did not consider that it was necessary to withdraw through a needle any of the contents of the stomach in order to verify that viscus.

DR. WARREN then showed a number of valve devices for gastric fistulæ. He then described an attempt that he had made to form, in animals, after the establishment of a gastric fistula, a valve composed of a fold of mucous membrane; this was simply a pleat in the mucous membrane that hung down valve-like, over the opening. This valve was in imitation of the one which existed in the celebrated case of Alexis St. Martin, and which added so much to St. Martin's comfort and welfare.

DR. F. S. WATSON then reported

A CASE OF PAPILLOMA OF THE BLADDER IN THE MALE, SUCCESSFULLY REMOVED BY THE SUPRA-PUBIC METHOD.[1]

and showed the patient.

DR. GANNETT showed, in a microscopic preparation, the bit of tissue, removed from the bladder at the first washing out, on which the diagnosis of papilloma was made.

It consisted of several papillæ, formed of delicate stems of connective-tissue supporting bloodvessels and covered by a many-layered epithelium. These papillæ were adherent to a common base made up of a vascular connective-tissue covered with epithelium. Finding such bits is absolutely diagnostic of papilloma of the bladder; and the surgeon may operate with the assurance of finding a new growth.

DR. CABOT said that he had examined Dr. Watson's patient some days before operation, and had distinctly felt an increased sense of resistance over the right portion of the fundus of the bladder, and was much surprised subsequently, at the operation, to see how small the tumor was, which had made itself thus manifest to the rectal touch.

In regard to the question of drainage or suture of the wound after operation, there are two important points to remember. First, that urine, even though foul, flowing freely over a wound, does little damage compared to that which comes about when urine perfectly fresh is forced into the tissues. So that although it is true that the supra-pubic drainage exposes the wound to contact with the urine, still this is by no means so dangerous a condition as we have when a bladder suture gives way and releases the urine into the previscal space more or less tightly closed by suture of the skin.

Much of the danger of this last accident is of course to be avoided by the introduction of drainage-tubes through the skin down to the proximity of the wound in the vesical wall.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, October 17, 1887.

DR. J. LEWIS SMITH, who was President of that Section, read a paper entitled,

A REVIEW OF SOME OF THE MORE IMPORTANT PAPERS PRESENTED TO THE SECTION OF CHILDREN'S DISEASES OF THE NINTH INTERNATIONAL MEDICAL CONGRESS.

The papers referred to were four in number, and

[1] See page 421 of this number of the Journal.

some of them, for lack of time, had been read only by title at the Congress. The first, on

PERTUSSIS AND ITS TREATMENT BY RESORCIN,

was by Prof. Moncorvo, of Brazil, who, Dr. Smith said, had made a special study of whooping-cough, and was now universally regarded as the highest living authority on that disease. The paper was written in French, and Dr. Smith proceeded to read a translation of its more important parts. In the year 1887, microscopic examination of the sputa of whooping-cough patients was made by a number of competent observers, and, believing in the bacterial origin of the disease, Moncorvo, himself, carried on an extended series of microscopical investigations; examining the sputa both of the catarrhal and the spasmodic stage, and of patients under treatment and not under treatment. Having given a *résumé* of these observations and their results, he stated that he was fully confirmed by them in the opinion that pertussis is due to the presence of specific micrococci. It was found that these were abundant during the spasmodic stage of the disease, and that they disappeared on the application of local disinfectants. Moreover, when the throats of guinea-pigs were swabbed with a solution containing these micrococci, a spasmodic cough was produced in the animals.

Moncorvo, therefore, concluded that pertussis was a disease having its seat in the entrance to the air passages, and the result of micrococci. In seeking for an appropriate remedy for local use he gave the preference to resorcin, among other antiseptics, on account of its solubility and lack of acidity; using it first in a 2 per cent. solution. In 1883 he published a first series of thirty cases treated with it, and in 1884 a second series of forty cases. In the meanwhile he had increased the strength of the solution used from 2 per cent. to 8 per cent. In 1885 he began to apply a 10 per cent. solution of hydrochlorate of cocaine before using the resorcin; and this he found lessened the intensity and frequency of the cough before the resorcin had had time to destroy the specific germs of the disease. This combined use of cocaine and resorcin was, in his opinion, the best treatment for whooping-cough now at our disposal, and if resorted to at the beginning, would sometimes reduce the length of the attack to four or five days. Of the efficacy of the treatment he had also had many assurances from medical men in various parts of the world. Any complications occurring in the course of an attack of pertussis were, of course, to be treated according to the nature of the trouble.

Having exhibited a number of plates showing the micrococci in the sputa which accompanied the paper, Dr. Smith went on to give an abstract of a paper written by Jules Simon, Physician to the Hospital for Sick Children, Paris, on

CEREBRAL IRRITATION OF YOUNG CHILDREN, AND PARTICULARLY OF INFANTS AT THE BREAST.

While many of the cases were doubtless due to alcoholism, insanity or syphilis in the parents, these would not explain them all. Having described the symptoms characterizing the condition, he stated that it might appear in the first month of life and usually terminated towards the age of five years in recovery, or in sclerosis or meningitis. Though, as had been said, some of the cases are due to hereditary influences, it was a fact that a large proportion of them resulted from the deplorable mismanagement of children at the breast that was unfortunately too common. It was not infrequent for nursing infants to be subjected to too much excitement, to noise, to bright lights, and other similar causes of nervous derangement, as well as to be given drinks such as tea, coffee or spirits, which had a similar effect.

The treatment for this form of cerebral irritation which Simon recommended was both hygienic and medicinal. It was necessary that a special and strict hygiene should be enforced, and all sources of excitement were to be suppressed. The child should be kept in the open air, and it was better, if possible, to remove it to the country, and preferably to the seashore. The remedy found most useful was bromide of potassium, which might be given in doses of from one and one-half to six grains to a child under one year, of nine grains to a child over one year, and of fifteen grains to a child over two years of age. Occasional intervals of three days' cessation of the drug were recommended. Laxatives were also often of service. In this way the predisposition to permanent neuroses could sometimes be checked, as there was always a condition of nervous irritability which preceded definite lesions.

In remarking upon this paper of Jules Simon, Dr. Smith said that it related to a matter of great importance, and one which he thought had not received sufficient attention from practitioners in general. Infants such as were described in the paper were often met with in American households, and the symptoms were apt to be attributed by their mothers and friends to dentition or intestinal worms. The causes of the cerebral irritation, however, were now always looked for elsewhere by the most intelligent physicians, and it was fully recognized by them that the vermifuge and the gum lancet, formerly so readily resorted to, were apt to do harm. There could be no doubt that in addition to hereditary influences the treatment the infant received had much to do with this nervous excitability, and that the habits of modern society interfered to no small extent with a well-regulated management of the nursery. While there were no structural lesions at first in this condition, it was important to remember that it might end in grave disease, such as sclerosis or meningitis; and this was a fact which ought to be known in every household.

In such cases he said he had, like Simon, been accustomed to use both hygienic measures and the bromide of potassium. It was beyond a question that the bromides were capable of relieving cerebral irritation when this was not due to any structural lesion. It was his practice to give two or three grains of the bromide of potassium to an infant of six months. In conclusion he said that he thought that Simon's paper was a very timely one, and would no doubt prove of much service in enabling practitioners to arrest the onset of irremediable cerebral disease.

The last two papers taken up by Dr. Smith were both by St. Germain, of Paris, on surgical subjects. The first related to

PRÆPUTIAL DILATATION.

Since circumcision was sometimes followed by serious accidents, among which profuse hæmorrhage and diphtheria were prominent, it was desirable that dilatation should be substituted for it in all cases, except

those in which the latter procedure was found to be impracticable. An examination of the statistics of the subject showed that this was the case in about one in every three hundred patients. The dilator that he employed was essentially the same as Nélaton's, except that there were two blades, instead of three, as in Nélaton's. Gradual and slow dilatation of the præputial orifice was practised, and afterwards, daily movement of the prepuce, alternately uncovering and covering the glans.

The other paper was on

IGNI-PUNCTURE OF THE TONSILS.

This, he believed, was an operation that was destined to replace tonsillotomy, when its merits were fully recognized by the profession. It was a perfectly safe procedure, and, therefore, free from the objections incident to tonsillotomy, on account of its danger. By the aid of a Smith's gag, a thermo-cautery was introduced into the mouth, and inserted into the tonsil to the depth of one centimeter. The operation was repeated every eight days, and from two to four sittings were required, at the end of which the tonsil would be found to be completely shrivelled up. It had proved very successful in the hands of St. Germain, and although he had now resorted to it in a large number of cases, no bad results had ever been noted.

Dr. Smith said he had applied to Dr. A. D. Rockwell for an expression of his opinion in regard to the procedure, as he knew of no one more competent to judge of its merits; and Dr. Rockwell had written that while St. Germain's reputation was such that a measure so highly recommended by him was worthy of the closest attention, his description of the method was too brief and vague to render a satisfactory discussion of the matter possible. He had used the thermo-cautery only in small external tumors, but, from our general knowledge of the action of this agent, he thought the claims of St. Germain very plausible. The galvano-cautery had the advantage over the knife of giving rise to much less danger of hæmorrhage or pyæmia; but, as its application was painful, and required from six to eight minutes at a time, he thought it very doubtful whether it could be successfully used in the case of young children. Igni-puncture, on the contrary, he believed, could be employed with facility, for the reason that it acted instantaneously, while it gave rise to much less danger of hæmorrhage, and would be followed by far better healing than tonsillotomy.

In regard to circumcision, Dr. Smith said that a number of cases of diphtheria had been reported as following the operation. The essential point about it was the removal of the smegma, and breaking up of any adhesions that may exist, and this, he thought, could be accomplished more successfully with dilatation. For dilating the prepuce, he was in the habit of using the long, slender forceps made for removing foreign bodies from the ear. The retraction of the prepuce could be best accomplished by the fingers, not oiled, and sometimes with the assistance of a simple probe. In the out-door department of Bellevue Hospital, Dr. Holbrook had informed him, this had been the plan of treatment resorted to for the last sixteen years.

DISCUSSION.

DR. C. A. LEALE said that he thought Dr. Smith was mistaken in supposing that the great mass of intelligent American practitioners did not recognize or appreciate the importance of the existence of cerebral irritation in infants and young children. It was a subject with which most good physicians were perfectly familiar, although there were no appreciable pathological changes at first. The only suggestion that he would make as regards treatment was that the bromide of sodium should be substituted for bromide of potassium, as he had found that, as a rule, it was much better borne by the stomach than the latter.

Dilatation of the prepuce had long been successfully practised in America, and St. Germain's paper in regard to it was nothing new here. There was one source of irritation which he had not seen alluded to by authors; namely, the existence of minute ulcerations under the prepuce. He was in the habit of touching these with nitrate of silver, after which they usually gave rise to no further trouble.

DR. J. R. MACGREGOR said, in regard to whooping-cough, that, in addition to the primary cause, he believed there was an intense neurosis, which it was necessary to control in order to deal satisfactorily with the disease. Almost every physician had some favorite remedy, and, personally, he had found that he could get the best results with oxalate of cerium. It was his practice to give five grains of this remedy once a day, early in the morning, in exceptional cases repeating the dose again at night. As to the prevention or removal of cerebral irritation in young children, he thought a great deal could be accomplished by simple education. This condition was, no doubt, often due to mistaken treatment on the part of parents, the children being played with too much, or otherwise subjected to over-excitement and stimulation of the nervous system. He could see no great objection to circumcision, and believed that many of the cases of diphtheria reported as following it were due to carelessness, on the part of the operator, with instruments, etc. He had tried dilatation, but had to confess that he had found it somewhat difficult and unsatisfactory.

DR. C. S. WOOD said that there was one point to which he desired to call attention in connection with the subject of cerebral irritation, and that was the condition of the mother when nursing her infant. The importance of quiet and tranquility at this time, on account of its influence on the child, was fully recognized by many mothers, as they had themselves observed the injurious effect produced by excitement, strong emotion, or over-fatigue. A useful hint, he thought, was afforded to physicians.

DR. J. W. S. GOULEY said that, in ordinary cases, the retraction of the prepuce, and washing away the smegma was sufficient; but when the præputial orifice was very narrow, it was not safe to attempt this, on account of the danger of producing paraphimosis, which was always a serious matter with children. In such cases, there was no question in his mind that excision of the prepuce was generally the best treatment. No sutures were required, and the wound readily healed, if left to itself. Dilatation, or, more properly, divulsion, was not an easy operation, and the younger the child, the more difficult it was to perform. It could be most satisfactorily accomplished by means of Trousseau's tracheotomy dilator, but the procedure was always to be condemned when the prepuce was narrow and indurated.

Dr. Alfred L. Carroll read a paper on

MINERAL-WATER MIRACLES,

after which Dr. Gouley presented a specimen of

DERMIC CYST OF THE SCROTUM,

in which fatty degeneration had been followed by calcareous infiltration, with the development of a small amount of osseous tissue, true bone-walls being found under the microscope.

Recent Literature.

Evacuant Medication (Cathartics and Emetics). By Henry M. Field, M.D., Professor of Therapeutics, Dartmouth Medical College. Philadelphia: P. Blakiston, Son & Co. 1887. 228 pages.

To the two groups of remedies, cathartics and emetics, considered in this work, it is well to have the attention of the practitioner directed, and if he reads this book, he will learn some things of interest not easily found in the text-books on therapeutics.

The author has written a work which includes more than would be found in a single text-book, but a large part of what is most useful would be found in any good one. The chapters on emetics are less valuable than those treating of cathartics. A diagram of the gastro salivary circulation, page 152, may also be found on page 316 of Dr. Brunton's work, and a diagram of the mechanism of reflex nausea, according to the author, "adapted from one first proposed by Lauder Brunton," is identical with one to be found on page 324 of Dr. Brunton's work, edition 1885.

Leçons sur les Maladies du Système Nerveux, faites à la Salpêtrière. Par J. M. Charcot. Tome troisième, (deuxième fascicule). pp. 129–518. Paris: 1887.

The publication of a volume by Charcot may well be regarded as a noteworthy event in the literature of diseases of the nervous system, even at a time when so many works of value as have been published in the past year have rendered the reviewer's task no small one. The present work which completes the third volume of Charcot's lectures on diseases of the nervous system, is, of course, made up of the reports of his lectures that have appeared from time to time in *Le Progrès Médical*, but all who have read them there will welcome them in their more accessible form. These lectures treat of double sciatica, word-blindness, soul-blindness, the amyotrophies, chorea, spiritualism and hysteria, isolation in the treatment of hysteria, hysteria in the male, hysterical monoplegia, hysterical coxalgia, hysterical contracture, and hysterical mutism. As it will be seen, the main part of the work is devoted to the functional neuroses, especially to hysteria and hypnotism. It is needless to speak of the value of these observations; the work of Charcot at la Salpêtrière on hysteria is known by reputation throughout the world, and the great clinical teacher's acumen was never more brilliantly displayed than on this subject. We cannot speak in detail of the observations here collected, but we must cite briefly his conclusions as to the etiology of traumatic hysteria. In his hypnotized patients, he finds that he can, by suggestion, produce symptoms that simulate precisely those presented in traumatic hysterical monoplegia, coxalgia, contracture, etc. He therefore concludes that the trauma which precedes and is supposed to cause these paralyses or other symptoms, really brings on a state of "nervous shock," which is allied to the hypnotic state. Of course, this state of "shock" is produced most easily in subjects predisposed to nervous troubles. In this state of "shock," or "obnubilation of the ego," as in the hypnotic state, any slight injury will act as a suggestion and produce the idea of motor impotence, which ultimately developes into a complete paralysis, hysterical paralysis, the paralysis dependent on idea, or the Schreckl\u00e4hmung of the Germans. In his analysis of the cases reported, he demonstrates most convincingly their hysterical character and their relations with the phenomena of the hypnotic state. We have space to call attention to but one more point, and that is the proofs that he gives of the necessity for isolation in the treatment of hysteria — not isolation from other patients necessarily, for his cases recovered in the wards of la Salpêtrière surrounded by all the hysterical patients there, but absolute separation from the patient's family and home surroundings — a *sine qua non* in the treatment of the disease.

Massage as a Mode of Treatment. By William Murrell, M.D., F.R.C.P. Third edition. Philadelphia: P. Blakiston, Son & Co.

The appearance of the third edition of Dr. Murrell's interesting little book at the end of nine months from the first, is proof of the favor with which it has been received. Having undergone the full period of utero-gestation, we predict for it a long life; for its digestion and assimilation of the most recent developments in the use of massage in medicine and surgery, evince a keener appetite and a sturdier growth than we expect to find at such an early age. Like its predecessors it makes a vigorous plea for the proper administration of massage in suitable cases, and it has many choice selections from various sources well connected with the author's own experience. Our readers will find it worth while to see what it says about the use of massage in heart disease, intermittent fever, fractures, chloral poisoning and the morphia-habit.

Reference to the case of "played out" should have been omitted, for massage is not mentioned in connection with it. We await with interest the result of the announcement that many surgeons are now employing massage in joint affections in England.

The plates at the end of the book are worse than useless, and we wish that the author had given the source from which he obtained them, so as to relieve himself of the responsibility of having reproduced them. The style of the American reprint has improved, and there are but few typographical errors.

D. G.

— The Crown Prince of Germany has recently had while at Toblach, a sharp attack of inflammation of the trachea and larynx. This fact, together with the cessation of bulletins in the English papers, after the Prince left that country, and a general undefined apprehension on the subject, has led the public press to express alarm as to his condition. Sir Morell Mackenzie authorizes the statement that up to October 22, the Prince's condition was highly satisfactory, there being nothing in the throat that need cause present alarm or well-grounded apprehension for the future.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 3, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

QUARANTINE ARRANGEMENTS AT THE ATLANTIC SEAPORTS.

WE referred last week to the danger of an importation of cholera inseparable from the arrival at our seaports, and especially at the port of New York, of vessels direct from the infected ports in lower Italy and Sicily, bringing large numbers of Italian immigrants of the lower classes and of filthy habits. We then knew a growing uneasiness existed, and was justified, in regard to what had already occurred at New York in the case of the *Alesia*, the *Britannia* and the *Independente*, and the possibility of the future occurrence of similar incidents could not be denied. This uneasiness has since found expression in the report [1] of a committee of the College of Physicians of Philadelphia rendered October 28th, and in a report of the chairman of the committee on Hygiene of the Medical Society of the county of New York, at a recent meeting of the society.

The Committee of the College of Physicians of Philadelphia was appointed October 5th "to consider the present danger of the importation of cholera into this country, and to secure concerted action among the Medical Societies in urging upon the State and National authorities the adoption of a uniform and efficient system of quarantine for all exposed ports," and consisted of Drs. J. C. Wilson, Shakspeare and Cleeman. This report considers first, the question of what are the requirements of an efficient maritime quarantine against cholera; secondly, to what extent do the existing arrangements at the ports of New York, Philadelphia and Baltimore fulfil these requirements. The committee only had time to visit these three ports, and therefore draw their conclusions from them. Dr. J. C. Peters in the report to the New York Society confined his statements to the quarantine arrangements at the port of New York alone. Both reports are substantially agreed as to matters of fact in regard to arrangements at Hoffman and Swinburne islands in the lower bay at New York harbor, and in the unfavorable conclusions which the reporters draw from their observations. The truth seems to be simply this: that whilst the buildings themselves are sufficient, they are not fitted with the necessary furniture or appurtenances, the water-supply is improperly located, the water-closet and washing arrangements are insufficient or out of order, and there is no resident physician, there are not suitable nurses. There is a fatal lack of surveillance on these islands.

The quarantine establishments at Philadelphia and Baltimore, the Committee of the College of Physicians points out, fail in the most essential requisites of the necessary number of properly equipped buildings for the isolation and observation of a large number of immigrants, but they have some bedsteads and bedding which are lacking at New York; moreover these stations, though without sick, are provided with resident physicians.

Dr. Peters thinks $5,000 would be sufficient to put Hoffman's Island — where immigrants are detained under observation — in complete and efficient order. If so, the discredit of the present state of things is the greater, especially at a port like New York, where the sum total of the fees is enormous, although we believe they are not responsible for such expenses. Dr. Peters suggests that the State Legislature order that a fixed sum should be appropriated annually out of the quarantine receipts to keep the buildings and apparatus in full efficiency, and the medical staff complete.

There is, of course, the other side to this question, which cannot be overlooked, which is, that we have to do with a very dirty people, of almost barbarous habits, in dealing with the southern Italian immigrants, and it is easier to provide knives and forks, washbasins and water-closets, than to make them use them. It would be better for our country if this immigration could be stopped entirely while cholera is prevailing as at present in Southern Italy and Sicily. As things are at present, or were until very recently, the *Alesia's* passengers might be detained under observation all winter, unless the cold ultimately did the work which the quarantine should have done at once.

We are glad to feel assured that the provisions for observation of the apparently well, and for the care and isolation of the sick at the quarantine station of the port of Boston are sufficient, and could be made in a few hours entirely satisfactory for any demand at all likely to be made upon them. Fortunately, for Boston, there are no steamship lines trading with southern Italy, and the only immediate duty liable to fall upon her health officials is the hunting up of the families or individuals, who, having slipped through New York, come here as they may go elsewhere through the country. The thorough disinfection of the effects of such arrivals, especially of their *old soiled clothing or bedding*, is of the first importance, and we understand that proper precautions have already been taken in the few instances where such unwelcome travellers have arrived and have been discovered.

[1] Medical News, (extra issue) October 29th.

PROFESSOR SARGENT ON THE ATHLETE.

The November number of *Scribner's Magazine* has a paper by Dr. Sargent, Director of Gymnastics at Harvard University, which deserves attention. He discusses the physical characteristics of a few students (if the word is allowable) at Harvard and Yale, who have distinguished themselves in certain branches of athletics, and compares the types of the rower, the sprint-runner, the pitcher, etc., one with another, besides alluding to the proportions of one or two celebrated professional athletes. The article is illustrated by admirable reproductions of photographs of which we hesitate to say all we think, lest we should appear partisan by our praise. The various measurements are represented by plottings on charts showing the departure of each from the mean. Dr. Sargent has described this method in an earlier paper, to which and to the present one we must refer those who would follow this investigation in its details. We offer only a general view.

The proportions of a certain short-distance runner are very interesting. Tall and spare, with clean-cut but not large muscles, long legs, and a good chest, this young man looks fitted to be a marvel of fleetness. That his looks do not belie him is proved by his record of one hundred yards covered in ten seconds, and better still, two hundred and twenty yards in twenty-two. Dr. Sargent holds that the characteristics of a sprint runner are relatively long legs, short body, full chest and small bones. The advantage of lightness of skeleton for the execution of rapid movements through long curves by the ends of long bones is quite evident. The height of short-distance runners is, we believe, generally above the mean (it is so in every case of which Dr. Sargent publishes the record) but there are exceptions, and in these especially it appears that a relatively long lower leg is of value. Myers is quoted as an instance. This celebrated professional runner is but five feet seven and one-half inches tall, but the length of his lower leg corresponds to that of a man of more than five feet ten, and his thigh to that of a man of five feet nine, while his sitting height is that belonging to a man of but five feet four inches. The characteristics of long-distance runners stand out less sharply, which is perhaps to be accounted for by short races being more fancied at college than long ones, so that there are fewer men who become really good in the latter. To our mind the most important characteristic that Dr. Sargent has observed in this class is the great girth of the lower part of the thorax.

The photograph of a Yale student, distinguished as a pole-vaulter, shows a striking but somewhat one-sided development. The muscles of the chest and shoulder are remarkable, but seem out of proportion to the rest of the figure. The lower part of the chest is small but the legs are finely modelled. In fact, this gentleman holds the inter-collegiate record for broad-jumping. In contrast to the sprint-runners are three members of the University crews and of the foot-ball teams of their respective colleges. They are marked by heavy frames, great muscular development, long backs and short powerful legs. Dr. Sargent attributes this great and well-distributed strength to foot-ball and to the gymnasium rather than to rowing. Foot-ball in spite of its dangers must, as he points out, be a great strength producer by its demands on all parts of the frame in running, pushing, pulling and resisting. Rowing as practised in these days of sliding seats makes great demands on the back and legs and tells less on the muscles of the chest and arms than of old. Dr. Sargent maintains, however, that it is a great exercise for enlarging the chest. The photographs of two base-ball players show much more symmetrical proportions than any we have as yet alluded to, but, unfortunately for any generalizations therefrom, we find that one is also a foot-ball player.

It is clear that some of the elements of success in certain sports are inborn and not acquired. If a short trunk and long legs are of great advantage to a sprint-runner and a long trunk and short legs to an oarsman, a young man who has the characteristics of either of these classes well marked can hardly hope to attain eminence in the other. Professor Sargent's theory of what should be done in such cases is a very sound one. "Add," he says, "to this inheritance the prolonged training that tends to cultivate these special powers to the extreme and we get sometimes a prodigy, but more often a failure." Now the aim of Universities in regard to physical culture is, we take it, to send out finely developed young men good for "all round" work and not prodigies in particular departments of athletics. Hence the man with naturally strong legs should take such exercise as will develop his weaker arms, and *vice versâ*. Dr. Sargent protests against the error into which a careless reader of his papers might easily fall, that the normal man is one whose every proportion shows the mean development. This is as much as to say that the normal man is one of symmetrical mediocrity. What is to be aimed at is to have all parts exceed the mean as nearly in equal proportion as may be. Needless to say that such acquired perfection is to be desired rather than attained. A man of precisely the mean height and the mean girth of chest cannot hope to increase the former in equal proportion to the latter. The principle, however, is an excellent one that the young man should labor to strengthen his weaker points rather than to develop indefinitely his stronger ones. We do not know that it is desirable that young men should aspire to be "record-breakers" in particular sports. It seems to us better that they should be moderately good in all, but we recognize that while human nature is what it is many will aspire to special excellence. It would be a curious problem for some expert in animal mechanics to decide just how a man should be built to use his strength to the greatest advantage in certain contests. Dr. Sargent raises the question but leaves the answer to time and statistics. "It would,"

he writes, "be of interest to know if an inch added to Myers' legs would have made him a greater runner than an inch added to his sitting height; or an inch added to Hanlan's long body would have made him a greater oarsman than an inch added to his relatively short legs."

There is one very important aspect of this subject that we are glad is not overlooked; it is, whether the athlete has the strength of constitution necessary to stand the strain of severe muscular exercise. We notice that, in the cases of two of the three foot-ball players and rowing men, the lung capacity is said to be insufficient to support the fine muscular development. Indeed, other factors have to be reckoned in this inquiry, and some of them do not lend themselves to tabulation. There are men whose organs show no defect, but who cannot bear the strain of prolonged exertion, especially if severe. Some cannot sleep, some cannot eat, some have nervous disturbances, all of which suggests that mental qualities are involved, as well as bodily ones, in the production of the athlete. We have heard the statement made, by one who well knew what he spoke of, that college men who aspire to success in both studies and athletics suffer in their constitutions. To restrain such from exertions that they cannot safely make should be, and, we believe, is, one of the duties of the professor of physical culture.

This topic suggests a number of interesting and vital questions. Space allows us merely to mention some of them. For instance, what exercise is to be recommended to the hard student? He has, perhaps, no knack for games; the weights or the bars are to him as cheerful as a treadmill; he cannot afford a horse, even if he knew how to ride. To him, a walk is about all there is left. It is cruelty to compel him to do work which he loathes, and he is likely to get little encouragement to learn games that he does not know. On the other hand, there are those to whom proficiency in games is an instinct, and the *gaudium certaminis* a stimulant — almost an intoxicating one. To advise these men to take sober walks, that they may avoid over-exertion and broken bones, is an absurdity, but they may accept and profit by advice as to how to best develop their powers. Still, to these the monotony of a gymnasium will, in the long run, be irksome. The tennis-player will admit that his right arm exceeds his left, without caring to correct it. In point of fact, he cannot correct it without taking time from his favorite game, and thereby injuring his proficiency. Is it likely that he will make this sacrifice from an abstract love of the symmetrical? and, after all, is it reasonable to ask that he should?

When we consider the numberless varieties of temperament and disposition, of health and courage, of inherited and acquired tastes, we see that the physical education of young University men is a task as difficult as it is important, a task likely to tax the best judgment of university authorities, as the Committee on Athletics at Cambridge could probably testify.

MEDICAL NOTES.

— The United States Consul-General at Rome, in his dispatch to the Treasury Department, under date of October 10, 1887, states that the vice-consul-general has just succeeded in obtaining from an official source the following facts in regard to the cholera in that city:

"From August 16, 1887, to October 7th, included, there were buried in the cemeteries of this city 204 bodies of persons certified in a special official register to have died of Asiatic cholera.

"As the ordinary portion of deaths in cases of cholera in Italy during the last four years have been a little less than 50 per cent., it may be safely assumed that there have been in Rome, between August 16th and October 7th, more than four hundred cases of cholera. There has been at no time more than ten burials in consequence of deaths by cholera during any one day since August 16th, and during the week ending October 7th, the average number of such burials was less than two per day. On October 6th and 7th, there was one such burial on each day. There were, on October 7th, ten cholera patients in the lazaretto, and thirty persons detained under surveillance in the house of observation. At one time in August or September, there were nearly three hundred persons so detained."

Dr. J. Y. Porter, United States quarantine inspector at Tampa, Fla., reports, under date of October 26, 1887, "a total of 225 cases of yellow fever, and 34 deaths to date. Fourteen new cases yesterday. About 80 sick now."

The Health Officer of the Port of New York, Dr. Wm. M. Smith, reports, under date of October 26, 1887, as follows: "The steamship *Britannia* was detained in first instance because diagnosis of surgeon of cases died at sea was unsatisfactory. On the 16th, a case developed that was very suspicious. Autopsy and biological examination confirmed suspicion of cholera — day after conclusion of investigation, 23d; another the 24th. The infection among the *Alesia's* passengers destroyed, there need be no apprehension concerning the *Britannia*."

— It is pleasant to see ourselves as foreigners see us. In the report of the Ninth International Congress by Dr. E. P. Hurd in the last number of the *Bulletin Général de Thérapeutique*, the venerable Dr. Leidy is transformed by the malicious types into Lerdy, and Drs. Warren and Parvin are merged into one personality — Warren-Parvin.

— We learn from an English contemporary that a well-known ex-executioner, Binns, is at the present time travelling in that country with an exhibition illustrating his method of dispatching the victims of the law. The performance is prefaced by a lecture account of Binns' own life and history, which is delivered by an assistant, and at its conclusion the ex-hangman steps forth, while a curtain ascends revealing a gallows and drop of the regulation pattern, and

dummy figure pinioned and standing ready for the adjustment of the noose. This last operation is next methodically gone through, and the final act of the drama completed by the withdrawal of the bolt and disappearance of the wax figure beneath the drop. The public attendance is large, the profits of the exhibitor are greater than the exercise of his practice on the living subject, and the effect on the public morals is about as bad as can be.

— Dr. Achilles Nordmann, of Basle, has, says the *Lancet*, published a description of twenty-five bowel lesions due to the operation of administering enemata. They include three complete perforations and ulcers, and wounds of various depths and sizes. The causes of these lesions seem to have been the use of defective instruments, ignorance of the direction of the rectum, catching of the transverse fold on the tube, extreme irritation of the mucous membrane of the bowel, and obstructions caused by certain conditions of the uterus, the fœtal head, or an enlarged prostate. As a rule, these lesions are to be found on the anterior wall of the rectum, from one to seven centimeters from the anus. They are not always easy to diagnosticate, as other foreign bodies or caustics may produce similar appearances. Tubercular and hæmorrhoidal ulcers may be mistaken for them; these are, however, generally higher up. A perforating wound gives rise to paraproctitis, but this is not necessarily fatal, though a stricture generally results.

BOSTON AND NEW ENGLAND.

— The annual meeting of the board of corporation and lady visitors of the Free Hospital for Women was held in Boston, October 27th. The whole number of patients admitted during the year was 129; of these, there were discharged cured or relieved, 98; discharged unrelieved, 3; left against advice, 6; entered for diagnosis only, 18; died, 4. The longest time of any one patient in the hospital was 216 days, the shortest stay one day, and the average 41, 12–31 days. In the out-patient department, there were 2,375 patients treated, being nearly double the number last year. During the year, Dr. C. P. Strong has been elected by the trustees to fill the vacancy occasioned by the resignation of Dr. J. W. Elliott, and Dr. Arthur W. Clark has been elected surgeon to out-patients, in place of Dr. F. W. Johnson. The Treasurer's Report showed the expenses for the year to be $7,562.86, of which about $1,000 was for legal expenses in defending a suit against the Hospital. The receipts, including a legacy of $5,000, were $14,539.

A committee of five was appointed to take into consideration the matter of erecting a new hospital building, and to select plans for the same. The election of officers for the ensuing year resulted as follows: Board of Trustees: George Dexter, President; Alfred Rodman, Treasurer; Nathaniel U. Walker, Secretary; Henry W. Daniel, William H. Baker, M.D., Grant Walker, Edwin H. Sampson, Henry C. Haven, M.D., Joseph W. Woods. Medical Staff: William H. Baker, M.D., Visiting Surgeon; F. H. Davenport, M.D., Assistant Surgeon; Charles P. Strong, M.D., Assistant Surgeon; Surgeons to Out-patients, Drs. C. P. Strong, J. B. Swift, Arthur W. Clark; Pathologist, W. F. Whitney, M.D.; Consulting Board, Drs. D. H. Storer, A. D. Sinclair, J. P. Reynolds, F. Minot. Financial Committee, Alfred Rodman, Henry L. Higginson, William H. Baker, M.D. The meeting then dissolved.

— At the meeting of the Norfolk District Medical Society, last week, Dr. B. E. Cotting read extracts from an interesting paper prepared by him, containing reminiscences, personal and professional, of the fifty years of medical practice which he has just completed. At the close of the meeting, Dr. Cotting entertained the members most hospitably at luncheon.

— The one hundredth anniversary of the founding of the Berkshire Medical Association for the improvement of the Art of Physick was agreeably and suitably celebrated last Thursday, October 27th, at Pittsfield by a dinner given by the Berkshire District Medical Society, at which Dr. Abner M. Smith, of Pittsfield, presided, Dr. Andrew M. Smith, of Williamstown, read an interesting historical retrospect, and Dr. J. F. A. Adams, of Pittsfield, read a poem. There was some after-dinner speaking in which U. S. Senator Dawes, Dr. Whittlesey, president of the Society, Dr. Thaddeus K. De Wolf the oldest living member, and others took part. The JOURNAL was represented by Dr. George B. Shattuck.

NEW YORK.

— At a meeting of the Medical Society of the County of New York, held October 24th, Dr. John C. Peters, Chairman of the Committee on Hygiene, made a report on quarantine and cholera, which gave an unfavorable account of the condition of affairs in the lower bay. "I found," he said, "great deficiencies on Hoffman's Island, and was told that far greater ones prevailed four weeks ago, when the *Alesia* landed her six hundred steerage passengers there, although all had had four years' continuous warning of cholera in Egypt, France, Italy, or South America. I heard that only $5,000 was wanted to put Hoffman's Island in complete and efficient order, and that, for the want of this paltry sum, not only this great city, but the whole country, had been, and still was, running great risks from various contagious or pestilential diseases, including cholera. . . . In default of table knives and forks, the emigrants are obliged to use their pocket-knives and fingers. This fact led me to my first clue to the persistence of cholera on Hoffman's Island. In order to be operative in the human body, I believe the poison has to be swallowed in food or drink. Cholera water contamination causes sudden and extended outbreaks of the disease, and the water-supply is inadequate at Quarantine. If dirty, cholera-soiled hands are put into the food, those who partake of it from the same dishes

will be liable to an attack. I learned that twenty-eight out of twenty-nine cases occurred in one room. In the infected room, families and groups of associates and messmates have been particularly unfortunate, because they ate out of the same dish. This seemed to me to be the clue to the whole mystery."

The best remedy for the existing evils, Dr. Peters thought, would be for the Legislature to order that a fixed sum should be appropriated each year out of the quarantine receipts, sufficient to keep the buildings and apparatus in full efficiency, and the medical staff complete.

— Considerable dissatisfaction has been found with Health Officer Smith for having permitted the passengers of the steamship *Independente*, many of whom were from cholera-infected ports in Italy, to land without being subjected to any detention at Quarantine, and for having allowed the *Britannia*, among whose passengers, at least, two cases of cholera, with one death, have since occurred, to come up to, and remain for several days, at Upper Quarantine, in free intercourse with persons from the mainland.

— At a meeting of the Quarantine Commissioners held October 27th, a dispatch was received from Dr. Smith, stating that there had been no sickness on the *Britannia* since October 24th. Some time was spent by the Commissioners in discussing what measures could be taken to prevent immigration from infected districts, and a resolution was passed requesting the President of the Board to communicate with the Secretary of the Treasury, as to whether ships with immigrants on board, from ports where cholera is prevailing, cannot be sent back again, and request that, if power to return such immigrants to the ports of embarkation lies with the Department, it should now be exercised.

— Dr. James Knight, surgeon-in-chief of the Hospital for the Relief of the Ruptured and Crippled, died October 24th. He was born at Tarrytown, Maryland, in 1810, and was graduated from the Washington Medical College, Baltimore, in 1832. He was the founder of the hospital referred to, which was built in 1870. In 1868 he published a work on the "Improvement of the Health of Children and Adults by Natural Means," and in 1874 one on "Orthopædics," a second edition of which appeared ten years later.

— By the will of the late Frederick H. Cossitt, a large number of charitable institutions, among them St. Luke's, the Presbyterian, and the Womans' Hospitals, the House of Rest for Consumptives and the Home for Incurables, have received legacies; the amount in most instances being $5,000.

— Dr. John M. Carnochan, the well-known surgeon, who was Health Officer of the Port for two years, under Governor Hoffman, died of apoplexy, October 29th. Dr. Carnochan was a native of Savannah, Ga., and was born July 4, 1817.

Correspondence.

GLEDITSCHINE-STENOCARPINE.

BOSTON, October 29, 1887.

MR. EDITOR,—In view of the commendation by Dr. Mattison of the so-called "newly-discovered alkaloid, gleditschine-stenocarpine," given upon page 419 of this week's issue of your JOURNAL, a paper on "What is Stenocarpine (Gleditschine)," by Prof. F. G. Novy, in Ann Arbor, contained in the November, 1887, number of the *Pharmaceutical Rundschau*, may be of interest. The article concludes as follows: "The so-called gleditschine or stenocarpine consists, therefore, essentially of 6 per cent. of cocaine hydrochloride; 0.50 per cent. of atropine sulphate, and about 0.33 per cent. of salicylic acid. The latter is used as a preservative." The article ends with the final word "*Humbugs*."

Yours respectfully,

BENNETT F. DAVENPORT, M.D.

THE MANY-TAILED BANDAGE IN FRACTURES ABOUT THE SHOULDER.

ROXBURY, October 26, 1887.

MR. EDITOR,— My attention has just been called to some remarks on the above head in the JOURNAL, of September 29, 1887, page 299, in an article by Dr. H. L. Burrell, Surgeon to Out-patients at the Boston City Hospital, comprising a record of "Four Months' Experience in Minor Surgery" at that institution. After mentioning several other appliances for the purpose of fixing the shoulder, namely, Velpeau's, Sayre's, Kelly's and Whitney's, (all by the names of their inventors), he goes on to say that the "'many-tail' bandage" (which is named first, and seems to have been oftener used than the others), "is open to the objection that it frequently cramps the arm and hand, so that the patient has not infrequently complained more of the bandage for the first forty-eight hours than of the injury for which the bandage is applied. This, of course, is true of all retention bandages in which the arm is flexed upon the chest, but has been especially marked in the 'many-tail' bandage."

Now I believe I had the honor of first suggesting the use of a many-tailed bandage for the purposes above described at a meeting of the Norfolk District Medical Society, held November 25, 1885. I there showed the form of bandage which I had devised, and also a model with the apparatus applied. I remember that one, at least, of the City Hospital surgeons was present at this meeting. The same appliance was afterwards exhibited before the Surgical Section of the Suffolk District Medical Society on June 6, 1886. At this meeting, two, at least, of the City Hospital surgical staff were present, both of whom, I recollect, did me the courtesy to commend personally my little contrivance.

Finally, a description of the same was published in the BOSTON MEDICAL AND SURGICAL JOURNAL, January 6, 1887, pp. 10 and 11, in an official report of the Surgical Section of the Suffolk District Medical Society, under the heading "An Apparatus for the Treatment of Fractured Clavicle." The only error in that report is in the date of the meeting at which the apparatus was shown, being January 6, 1886, instead of May 5, 1886, as stated in the report.

The apparatus (*vide. loc. cit.*), consists of a broad belt of sticking plaster to go round the chest, and a many-tailed bandage of stout cloth sewed across the back of the plaster by two parallel seams, three inches apart. The plaster belt is then adjusted round the chest so that the space between the seams will fall exactly in the mid-axillary line, the axilla padded if necessary, and the cloth "tails" brought round the arm and pinned. This bandage does not, and cannot produce pain, unless drawn too tight.

What kind of a "many-tail" bandage Dr. Burrell made use of in his experiments is not stated, but I have reason to know that an exceedingly ill-conceived imitation of my bandage was introduced into the City Hospital very shortly after the exhibition of my apparatus before the two learned

societies above named. On July 19, 1886, (six months after the showing of said apparatus, and six months before the published description of it in the JOURNAL), I was told by a personal friend, then a student of the Harvard Medical School, that he had seen a bandage similar to mine used at the City Hospital the previous spring, and heard it described to the students as a new device (though without mention of my name), and that the hospital surgeons (or their assistants) had made the "tails" which go round the arm of *sticking-plaster* instead of *cloth*, as used and recommended by me.

Now, it is perfectly self-evident that these plaster strips must exert most painful traction on the skin, obstruct the free circulation of the limb, and increase the danger of compression, swelling and gangrene; whereas cloth yields a little, and can be loosened or tightened according to the patient's feelings. Then, if the space between the two seams on the inside of the arm, especially intended to prevent pressure on the brachial vessels and nerves, happened to be left out also, and the ends drawn smoothly and tightly as possible, after the manner of the artistic hospital dresser, it is easy to see how the hospital bandage *might* have produced all the ill consequences which Dr. Burrell charges against it. I am sure I have never experienced any such results, nor do I understand how any surgeon, possessed of that reasonable amount of skill and science which the public has a right to expect, could be capable of applying a bandage which, during the first forty-eight hours, produced more pain to the patient than the injury for which it was applied. (!)

The question remains to be answered, as it seems to me:

First. Whether the condemned bandage was properly made?

Second. Whether it was properly put on?

Yours respectfully,

EDWARD T. WILLIAMS, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 22, 1887.

Deaths reported 1.828: under five years of age 667; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 389, consumption 258, lung diseases 179, diphtheria and croup 100, diarrhœal diseases 85, typhoid fever 61, malarial fever 24, scarlet fever 24, cerebro-spinal meningitis 10, whooping-cough 10, measles seven, puerperal fever four, erysipelas three, small-pox (New York) one. From malarial fever, New York 11, New Orleans five, Baltimore and District of Columbia three each, Philadelphia and Nashville one each. From scarlet fever, New York 10, Philadelphia and Boston four each, Chelsea three, Baltimore, Pittsburgh and Lowell one each. From cerebro-spinal meningitis, New York, Fall River, and Springfield two each, Boston, Baltimore, Milwaukee and Chelsea one each. From whooping-cough, New York and Philadelphia three each, Baltimore, New Orleans, Pittsburgh, and Milwaukee one each. From measles, New York four, Boston, Baltimore and Milwaukee one each. From puerperal fever, District of Columbia two, Boston and New Orleans one each. From erysipelas, New York two, Baltimore one.

In 24 cities and towns of Massachusetts with an estimated population of 1,109,534, the total death-rate for the week was 19.28 against 18.92 and 20.71 for the previous two week.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending October 8th, the death-rate was 17.5. Deaths reported 3,099: infants under one year of age 815; acute diseases of the respiratory organs (London) 986, scarlet fever 96, diarrhœa 92, whooping-cough 66, fever 58, diphtheria 38, measles 46, small-pox (Sheffield) 13.

The death-rates ranged from 13.9 in Bradford to 30.1 in Preston; Birmingham 15.5; Blackburn 24.1; Hull 15.6; Leeds 19.1; Leicester 17.5; Liverpool 19.3; London 15.7; Manchester 25.6; Newcastle-on-Tyne 19.9; Nottingham 18.4; Sheffield 19.1.

In Edinburgh 18.4; Glasgow 18.7; Dublin 24.2.

The meteorological record for the week ending October 22, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Oct. 22, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 22, 1887, TO OCTOBER 28, 1887.

GREENLEAF, CHARLES R., major and surgeon. Will proceed from this city to the places hereinafter named, in the order in which they are named, for the purpose of investigating the methods of examining recruits at the depots and rendezvous located thereat, and of instructing recruiting officers in matters pertaining to such examinations: Baltimore, Md., Philadelphia, Pa., Camden, N. J., New York City and David's Island, N. Y., Boston, Mass., Portland, Me., Albany and Buffalo, N. Y., Cleveland, Ohio, Detroit, Mich., Chicago, Ill., Milwaukee, Wis., St. Paul, Minn., Jefferson Barracks, and St. Louis, Mo., Cincinnati and Columbus, Ohio, and Pittsburgh, Pa. S. O. 248, A. G. O., October 25, 1887.

CLEARY, P. J. A., major and surgeon. Ordered to proceed from Fort Huachuca to Fort McDowell, and report to the commanding officer for duty as post-surgeon. S. O. 111, Department of Arizona, October 18, 1887.

RICHARD, CHARLES, captain and assistant surgeon. Granted leave of absence for one month to take effect when his services can be spared by his post commander. S. O. 247, A. G. O., October 22, 1887.

BURTON, H. G., captain and assistant surgeon. Ordered from Plattsburgh Barracks, N. Y., to Watervliet Arsenal, N.Y.

MERRILL, J. C., captain and assistant surgeon. Ordered from Watervliet Arsenal to Frankford Arsenal, Pa. S. O. 249, A. G. O., October 26, 1887.

JARVIS, NATHAN S., first lieutenant and assistant surgeon. Ordered for field duty in Department of the Platte. S. O. 246, A. G. O., October 21, 1887.

JARVIS, NATHAN S., first lieutenant and assistant surgeon. Ordered from Department Platte to Department Missouri, for duty in the field. S. O. 249, A. G. O., October 26, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 29, 1887.

BATES, N. L., medical inspector. Ordered to hold himself in readiness for orders to the "Trenton."

HESLER, F. A., assistant surgeon. Ordered to examination for promotion.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — The regular meeting will be held at the Medical Library, 19 Boylston Place, Monday evening, November 7, 1887. Dr. Vickery will present a paper upon "Appendicitis, with Report of Cases."

CHARLES P. STRONG, M.D., *Secretary*.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. — THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, November 9th, at 7.45 o'clock. Business: the Election of a Chairman for the ensuing year. Papers: Dr. E. O. Otis, "Hints to Physicians sending their Patients to Colorado." Dr. E. L. Cail, "A Case of Chronic Pancreatitis, with Symptoms resembling Malignant Disease." Dr. Douglas Graham, "Local Massage for Local Neurasthenia."

ALBERT N. BLODGETT, M.D., *Secretary*.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting of the Society will be held at the Medical Library Rooms, No. 19 Boylston Place, on Thursday, November 10th, at 4 o'clock, P.M. Paper: "A Year's Experience in Hospital Practice," by Dr. H. O. Marcy.

H. J. HARRIMAN, M.D., *Secretary*.

AMERICAN ASSOCIATION FOR THE CURE OF INEBRIETY. — This Association will hold its semi-annual meeting at the Turkish Bath Hotel, Columbia Heights, Brooklyn, November 9th, at 12 M. The following is a list of the papers and addresses to be read: The President's Address, "On the Responsibility of the Inebriate," will be delivered by Joseph Parrish, M.D., Burlington, N. J. "Report on the Colonial Congress on Inebriety, in London," by Dr. T. D. Crothers, Hartford, Ct. "The Pathology of Inebriety," by Dr. Norman Kerr, London, England. "The Physiology of the Drink Impulse," by Dr. J. T. Searcy, of Tuscaloosa, Ala. "Cocaine Toxæmia," by Dr J. B. Mattison, Brooklyn, N. Y. "The Power of Alcoholic Influence," by Dr. T. L. Wright, Bellefontaine, Ohio. "Turkish Baths in Inebriety," by Dr. C. H. Shepard, Brooklyn, N. Y. "Hygiene in the Treatment of Inebriety," by Dr. Albert Day, Boston, Mass. "Report on Asylum for Inebriates in New Zealand and Australia," by Dr. D. McGregger, Gov't Inspector, New Zealand. "Sexual Insanity in Inebriety," by Dr. L. D. Crothers, Hartford, Ct.

OBITUARY.

PROFESSOR VON LANGENBECK.

Bernhard Rudolph Konrad von Langenbeck, one of the most illustrious surgeons of the world, died September 30th, in the seventy-seventh year of his age, at Wiesbaden, where he had resided of late years. He was born in 1810 at Horneburg. He studied at Göttingen, and graduated in 1835 with the dissertation, "De Retinæ Structuræ Penitiore." Soon after he published his essay on the "Origin of Venous Cancer and the Possibility of Transferring Cancer from Man to Animals." He then became Extraordinary Professor in Göttingen, and wrote an essay on "Persistent Spasm of the Fingers and the Application of Division of Muscle and Tendon in its Treatment." Subsequently he busied himself with the questions of "Stammering and the Employment of Myotomy in Defects of Speech arising from Spasm," and the "Immediate Union of Wounds by Exclusion of Air." In 1842 he became Professor of Surgery and Director of the Friedrichs Hospital. In 1848 he was Director-General of the army of the Duchies against Denmark; and in 1847, after Dieffenbach's death, he was appointed Director of the Clinical Institute for Surgery and Ophthalmic Surgery. Amongst other essays of minor importance are the following: "Subcutaneous Osteotomy"; "The Permanent Warm Water Bath in the Treatment of Large Wounds, especially of the Stumps after Amputation"; "On the Extirpation of Interstitial Uterine Fibroids"; "The Osteoplastic Resection of the Upper Jaw"; "Essays on the Surgical Pathology of Veins"; "On Cleft Palate"; "On Resection of the Ankle in Gunshot Wounds"; "On Gunshot Wounds of the Joints"; "On the Terminations of Resection Operations in War"; "On Extirpation of the Pharynx"; "On Gummatous Tumors."

Clinical Lecture.

SYMPTOMS INDICATING INJURY OF THE ABDOMINAL ORGANS. RECOVERY UNDER MEDICAL TREATMENT.[1]

BY JOHN H. PACKARD, M.D., *Surgeon to the Pennsylvania Hospital.*

GENTLEMEN: The first case that I shall show you this morning is a man who was admitted to the hospital twelve days ago. He was injured by the fall of an archway, burying him under a large quantity of bricks and timbers. On examination, it was found that he had fracture of the femur, fracture of several ribs, and very severe contusions about the abdomen. I wish to call your attention particularly to this latter injury. This class of cases often present considerable difficulty.

When this man was admitted, there was a good deal of shock, the temperature being 98°. As I have said, there was marked contusion of the abdominal walls. There was distinct tympany, the abdomen being greatly distended. There was a great deal of pain and distress, and occasionally, a large quantity of wind would be expelled, with relief. There was difficulty in urination, and a catheter had to be employed for several days. During the first few days, the urine contained blood. The bowels were constipated, and it was difficult to secure a movement. The tongue was dry and brown. The pulse was rapid, and the temperature, which had been 98°, went up to 100°, and, on one occasion, to 101°. It was a serious question with me whether or not there had been some damage to the abdominal viscera, and whether it would not be right to make an exploratory laparotomy, and treat the injury so far as might be possible. Several times, I was about calling a consultation to consider the question, but, on each occasion, on going into the ward, the patient was found in such good condition that the matter was postponed, and he finally improved to such an extent that the idea of any operation becoming needful was abandoned.

The treatment has been expectant, consisting in the use of small doses of spirits of turpentine internally, with turpentine stupes and poultices externally. Under this course, the patient has progressed in an entirely satisfactory manner. Another symptom which I omitted to mention was that, while the tympany was present, there was marked distension of the superficial abdominal veins. This distension always indicates some obstruction to the circulation within the abdomen. If the internal circulation is free, the superficial veins are not apparent. In Cruveilhier's "Atlas of Pathological Anatomy," you will find illustrations of some marked instances, where, as a result of abdominal disease, causing pressure on the internal veins, the superficial veins have become greatly distended.

The points of special interest in this case were the gravity of the abdominal symptoms, the question that arose with reference to the propriety of operative interference, and the subsidence of the symptoms under strictly medical treatment.

A METHOD OF PREVENTING STIFFENING OF THE HIP JOINT IN FRACTURE OF THE THIGH.

This little boy, nine years of age, has a fracture of the thigh, which was received four weeks ago. The limb is in very good line, and there is no shortening whatever. As you see, the child is sitting up in bed. When I was a resident in this hospital, something over thirty years ago, such a thing would not have been allowed. The child would have been kept flat on his back for six weeks, at least. It is to this point that I shall ask your attention in the consideration of this case. This fracture is, I think, now in such a condition that the boy may be allowed to sit up without fear of any disturbance of the union. If he were going to sit up for any length of time, I should have extension applied.

Under this method of treatment, the period of confinement is materially shortened, and, while this may not be a matter of moment in this instance, it is sometimes very important. In some cases of fracture of the neck of the thigh-bone in old persons, the stiffening of the hip-joint is among the most serious of the after-consequences, and it is one of the most difficult to obviate. After recovery from the fracture, the patient finds it necessary to use crutches, and can only go about with the utmost care for some time, on account of the stiffening of the hip-joint. To obviate this, I make the patient begin to sit up about the tenth day, while the extension is allowed to remain. I gradually set him up more and more, keeping the hip-joint limber, and when he is able to get out of bed, there is a considerable degree of motion in the hip, and he is often able to walk without a crutch, or even a cane.

Some time ago, I was called to see a man seventy-two years of age, a workman in a carriage-factory who had fractured the neck of his femur by tripping over some obstruction and falling backwards. He was a man of perfectly sober and temperate habits. I stated, thought, and told him that he would not be able to walk again without the use of a cane or a crutch. Extension was applied, and, at the end of the tenth day, I made him sit up in bed, still keeping up the extension. Fourteen weeks after the fracture, there was no appreciable shortening. Calling at the factory, I learned that the man was at work. For a short time he used a cane, but he soon discarded this, and was able to go up and down stairs without either a crutch or cane, and, while walking on a level, there was no apparent limp. I exhibited this man at the Philadelphia Academy of Surgery, and, from an examination of the man's movements, none of the members were able to state which was the injured limb. Both thighs could be raised with equal facility. When, however, the limbs were examined with care, there was a slight amount of callus, which showed the seat of the original injury.

STAB-WOUND IN THE BACK.

This man was admitted to the hospital ten days ago, with a stab-wound at the lower portion of the posterior aspect of the left chest. The wound was apparently made with a sharp knife. Over and around this region there is now dulness on percussion, and, on auscultation, I am able to hear nothing, although, a little higher, the respiratory sounds are quite distinct. I think that there is no pleuritic effusion, but that the reason that I hear nothing on auscultation is the presence of the large amount of thickening of the tissues external to the pleural cavity. The resident surgeon informs me that friction-sounds were present a few days ago. It is not at all improbable that, as a re-

[1] Delivered at the Pennsylvania Hospital, April 20, 1887.

sult of the inflammation, there has been a localized pleurisy, giving rise to a few adhesions. There is evident thickening of the external tissues. The point of principal interest in connection with this case is that it has been treated in an entirely expectant manner. If we had enlarged the wound under the impression that we must do something, we might have done serious damage. The man could scarcely have done better under any circumstances.

RELAXATION-SUTURE.

The next case is the man from whose buttock I removed the tumor four days ago. On the day following the operation, the temperature went up to 100°, but since then it has been normal. Such a rise of temperature often occurs just after an operation; it does not mean anything, and is not an indication of serious trouble. The relaxation-sutures have been removed, and, as you see, there is a slight mark left where the thread was carried across the wound. You will remember that, in this case, I passed the relaxation-sutures across the deep portion of the wound, and, after securing the thread on each side to pieces of catheter, to prevent cutting of the skin, carried the free ends across the wound, and tied them together. This is not as satisfactory as the plan which I usually employed, but which I omitted on this occasion, on account of want of time. This I do as follows: I have three or four needles threaded with fine silk, the ends of the sutures being formed into loops. Through the loop is passed the relaxation-suture, and carried across the deep portion of the wound, and the fine thread removed, leaving a double ligature across the wound, with a loop on one side, and free ends on the other. The remaining relaxation-sutures are applied in the same way. A piece of catheter is then slipped through the loops on one side, and, on the other side, the free ends are tied over a similar piece of catheter. This, which is simply the old-fashioned quill-suture, has the advantage that there is no cross-tension. Instead of having a tendency to pull across the wound, the tension is downwards, and the external wound is left free. While this groove in the skin does no harm, the application of the suture in the latter way would have been better. The wound is doing very well, and, in a short time, will heal, leaving scarcely any scar.

PROLAPSE OF THE RECTUM. TREATMENT BY THE ACTUAL CAUTERY.

The last case which I shall bring before you is a case of prolapse of the rectum, which is well worth your seeing, as it occurs under somewhat peculiar circumstances. You often find in weakly children, or in old persons enfeebled and broken down by disease, such relaxation of the sphincter that prolapse takes place. In this case, however, the prolapse has been produced in a manner similar to that which obtains in cases of stone in the bladder. It frequently happens in cases of vesical calculus that, in the straining efforts during urination, the bowel comes down, and, in weak children, the bowel often comes down without straining. This man is forty-eight years of age, although he looks older. Until ten years ago, he enjoyed good health, with the exception of an attack of malaria in 1878. Ten years ago, he was treated for stricture of the urethra, which was dilated three times a week for two months. Six years ago, he had a sudden attack of retention of urine. He then went to a hospital, and was treated with bougies. He left the hospital, and, three months later, went to another institution, where he says he was operated on for hæmorrhoids. A few months later, he again had retention, and bougies were again employed. Two and one-half years ago, he first noticed that the rectum came down. This has been gradually getting worse, until, on admission, every time he passed water there was a great prolapse, and an involuntary discharge of fæces. Trying to pass an instrument through the urethra, I found that it was stopped at the prostate. I then used a gum instrument, with a stilette, and passed it into the bladder without difficulty.

Ten days ago I applied the actual cautery, making eschars radiating from the centre, applied carbolized oil, and returned the bowel. This has been attended with good results. There is now much less straining, and much less of the rectum comes down. There is, however, still some displacement. I shall, to-day, give ether to the first insensibility, and shall make a few more applications of the cautery. In this case, there is no enlargement of the prostate gland, and, in fact, the prostate is unusually small for a man of this age. There has probably been abscess of this gland, and loss of its substance. Hence, there is no point of support either for the bladder or for the bowel, and, as a result, the relaxed rectum comes down with great ease.

Original Articles.

A DISSECTING MESENTERIC ANEURISM.[1]

BY E. N. WHITTIER, M.D.,
Assistant Professor, Clinical Medicine, Harvard Medical School; Visiting Physician, Massachusetts General Hospital.

IT is my privilege to present a case, exceptionally complete, in demonstration of the subject of this paper: A. B., male, twenty-one years of age, entered the Massachusetts General Hospital early in October, 1886, remained in the Hospital six-and-a-half months, and died there, and the report of the autopsy by Professor Fitz establishes the diagnosis, as given above.

What might well be called the pathological career of this patient began four years before he came under my care, was somewhat marked between the years 1882 and 1886, but became continuous and progressive from the date of his admission to the Hospital until his death.

The family history was good. There was neither specific taint nor alcoholic habit. In 1882, he had two attacks of rheumatic fever of marked severity. From their immediate effects, he enjoyed singular immunity; but, in July, 1886, while on his vacation, and among the mountains, making prolonged and violent over-exertion, there were well-defined indications of circulatory disturbances — vertigo, palpitation, dyspnœa, occasional orthopnœa, cough, with bloody expectoration, and functional disorders of digestion, with loss of weight, strength, and color.

The earlier Hospital examinations proved the existence of great cardiac enlargement, with well-marked cervical pulsations, extreme distinctness of arterial movements in all the superficial arteries, and the "tone" in radials, crurals, and tibials associated with

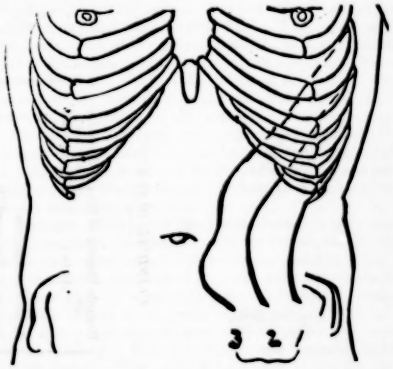
[1] Read before the Boston Society for Medical Observation, October 3, 1887.

incompetence of the aortic valves; there was, also, to be felt the hammer-pulse, less than is usually accepted as diagnostic, rendered less by the weakness of the heart's action, and strengthening the opinion formed by those observing the patient, that the limit of cardiac compensation had been nearly reached. The hands and feet were cold, the face was dusky, the lips were cyanotic, there was much dyspnœa, and great weakness. The temperature was irregular and somewhat elevated, and, for the first two weeks, resembled that seen in mild typhoid, tuberculosis, the lower grades of septic infection, as well as in pernicious anæmia and pseudo-leukæmia. In the third week, occurred the first of a series of phenomena which made this case noteworthy. The records describe joint-pains, with redness and swelling of the elbows, wrists and hands, knees and ankles, controlled by salicin. At first, no change was observed in the character or quality of the heart-murmurs noticed on entrance, but, with increasing cardiac disturbance and præcordial distress, an endocardial murmur developed. This was heard best over the dilated ventricle, was loud and harsh over the aortic area, and was propagated upwards. Between the middle of October and the 10th of November, there were three separate attacks of joint inflammation, and a constant increase in the evidences of concurrent endocarditis.

November 10th. The record states that, during the night, the patient was seized with severe pain in præcordial region and left hypochondrium, quickly collapsed, and was with great difficulty revived. The next morning, temperature was 96.5° (102° previous evening), the pulse was 130, and respiration 40.

Thirty-six hours later, a similar outbreak of pain was recorded, with like effects.

November 12th. The urine was bloody, albuminous, and contained casts. There was vomiting. The condition of the patient was extreme. Hands and feet were cold, pulse varying from 120 to 140, and there was great pallor.

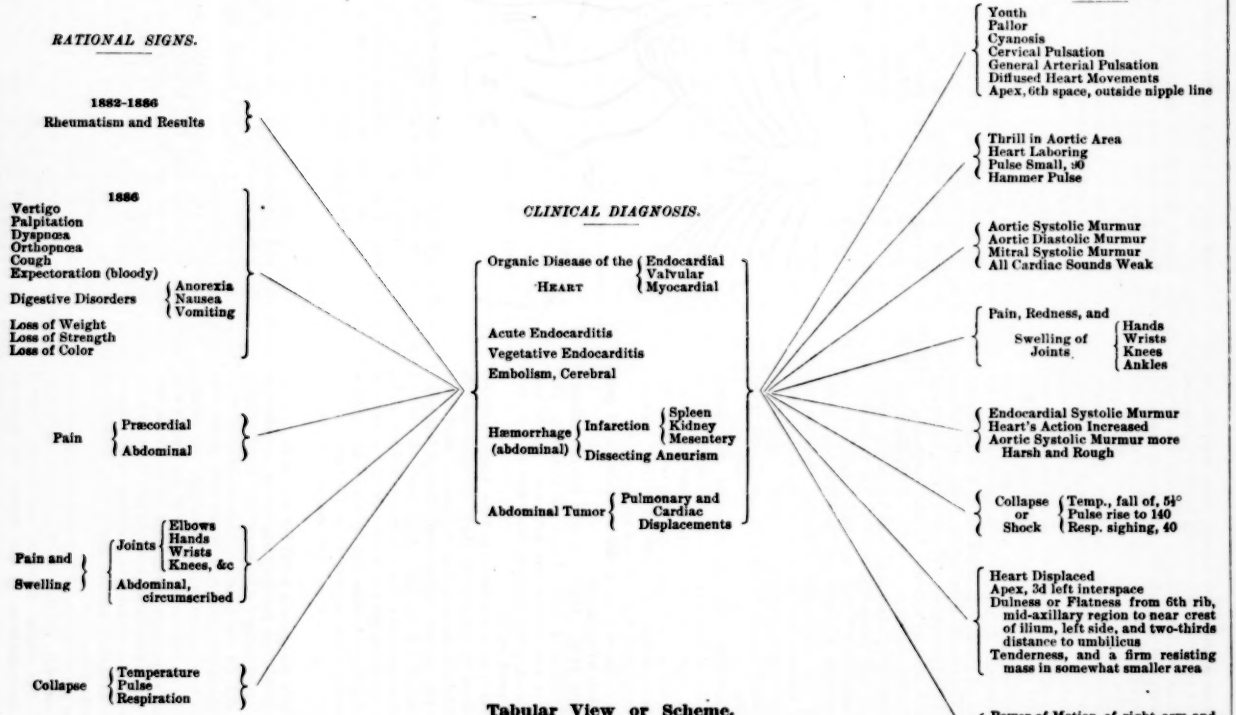


The heart's apex was found to have been displaced upwards from the sixth to the third interspace, on left side, and dulness merging into flatness extended from the sixth rib, axillary region, down through left hypochondrium and left lumbar region, nearly to crest of ilium, and transversely almost to the umbilicus, while, from the lower margin of rib, on left side to crest of ilium, and quite to median line in umbilical region, a firm, resisting body, regular in outline and surface, and tender on pressure, could be mapped out by palpation.

But slight change was noted for several days, when it was recorded that the skin was sallow or yellowish in hue, suggesting absorption of blood-coloring matter; and, on the same day, mention is made of return of severe pain, this time in left side, midway between ribs and crest of ilium. This pain was quickly followed by an increase in the size of the tumor, with diminished respiratory movements of left chest, dulness, on percussion, through whole left front, and deficient respiration-sounds; the position of the heart's apex was as before, on the upper margin of fourth rib, mammary line.

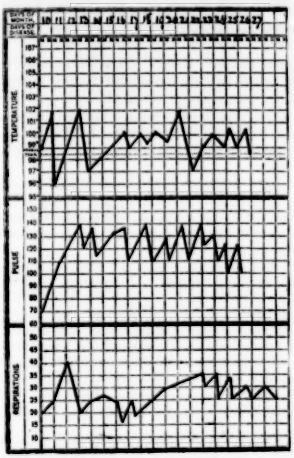
The length of this paper forbids detailed description of each outbreak, for they were numerous, each characterized by similar features, and every interval marked by subsidence of the tumor, its contents slowly ebbing, as if by absorption, or rapidly increasing, as by blood escaping into a cavity limited by retaining walls.

Mention should, however, be made in the report that, from November 10th to February 27th, there were six painful paroxysms, characterized, as already described, by severe constitutional symptoms and the development of an abdominal tumor, or the increase in size of one previously developed, but subsequently diminishing, until, in the latter part of February, the attacks of pain were nearly every day, and the sign and position of the tumor quite constant.



On March 8th, at the time of the morning visit, the patient was found to be articulating with difficulty, tongue protruded to right side, and motion of right arm and leg greatly impaired. Partial recovery from this took place quite quickly. During the rest of March and the early part of April, there was gradual failure of all powers, and the patient died on the 15th of April, after a few hours of semi-coma, in which there were strongly-marked evidences of great circulatory embarrassment.

I avail myself of the opportunity presented by this case, to ask your consideration of a plan or scheme of study with reference to greater accuracy in diagnosis.



The plan which I have pleasure in placing before you readily explains itself, in the tabular view of symptoms arranged as rational and physical signs, and grouped in the order of diagnostic values. It is analogous to the methods of analysis adopted by the most accomplished clinicians, and although susceptible of modification and improvement (for the art of discriminating disease is progressive), I believe it can be confidently appealed to as a safe and reliable guide to reach desired conclusions.

"The study of any complicated subject tends of necessity to its arrangement into branches; closely connected as these are and forming always part of a whole, they are not only capable of distinct treatment, but frequently become more intelligible as they are so treated." I know of nothing to which this axiom is more applicable than to the analysis of the complex phenomena of disease, and it is with full confidence that it will receive your commendation that I lay before you the accompanying diagram as a study of the subjective and objective signs or symptoms found in the case reported this evening.

Tabular View or Scheme.

Subjective and Objective Symptoms.

Dr. Fitz kindly consents to the use of the report of the autopsy in connection with the clinical history of the case.

AUTOPSY SEVENTEEN HOURS AFTER DEATH, BY PROFESSOR R. H. FITZ, M.D.

Body much emaciated; skin and lips unusually pale, right elbow and hand swollen, feet strongly flexed, slight rigor mortis.

Head. Not opened.

Pericardium. Contains half-pint clear yellowish fluid.

Heart. Nearly twice the usual size; apex broad and round, formed by the left ventricle. Sub-pericardial tissue gelatinous. Aortic valves did not hold water, pulmonary valve sufficient, the mitral admitted two fingers, the tricuspid four, the right side of the heart widely distended with a differentiated clot, the left ventricle also contained considerable dark clotted blood. The aortic crescents, thickened, moderately retracted, covered with numerous opaque, white, moderately firm adherent excrescences. The anterior crescent torn through. The aorta just above the valve showed similar excrescences, others were found attached to the parietal endocardium, below the crescents also near the free edge of the aortic curtain of the and mitral valve, projecting from each surface. The anterior sinus of Varsalva was dilated into a pouch as large as a cherry-stone, a smaller pouch was found in an adjoining sinus, its intima opaque and corrugated; no other abnormal appearance observed in other valves. Both ventricles, especially the left, dilated, the wall of the latter moderately thickened. The posterior wall showed numerous patches of fibrous thickening, and occasional spots of ischæmic necrosis. The branches of the coronary artery leading to these parts contained emboli, the largest of which were of the size of a grape-seed and resembled in color and consistency the vegetations attached to the aortic valves.

Left Pleural Cavity wholly obliterated by old adhesions. Pleura not remarkably thickened. Occasional dense and firm pleural adhesions on the right side.

Lungs. Both lungs extensively œdematous, and moderately infiltrated with solid material producing a reddish-gray color, with smooth surface. In the right pleural cavity was a pint of clear yellow fluid.

Spleen. The spleen was nearly doubled in size, somewhat softer than normal and pale in color. A more or less wedge-shaped nodule of reddish color, as large as a walnut, extended from the surface of the spleen towards the centre near the upper third of the organ; another smaller and similar nodule was found near the lower border; on section the structure of the spleen was readily made out.

In the region of the left kidney was a renal-shaped sub-peritoneal tumor 9 x 6 x 4 inches. It was soft, some fluctuating and was composed of clotted blood in part discolored and laminated, in part of a dirty red color and of homogeneous consistency. The mass lay upon the kidney and was crossed by the descending colon. Further examination shows by dissection the mesentery two aneurisms near the intestinal attachment. The upper was of the size of a small cherry and had a thick wall. The lower was the hæmatoma previously described, and was filled with a thrombus: The walls of the aneurism were relatively thin. Further dissection of the wall of the peri-nephritic hæmatoma showed that the former were wholly outside of the kidney, which was very much flattened, the wall was quite dense towards the kidney, the absence of any evidence of the supra-renal capsule, and the discovery of the mesenteric aneurism suggests that the peri-nephritic hæmatoma may have been a dissecting aneurism.

Kidneys. The left kidney was flattened, pale and gray, the outer two-thirds lost in the tumor, the pelvis and calices were considerably dilated, and the ureter was shrunken, diminished in size, perhaps one-half, and imbedded in somewhat indurated fibrous tissue, from the kidney to the brim of the pelvis. The left renal artery and vein showed nothing abnormal outside the kidney. The left supra-renal capsule could not be found. The right kidney was somewhat enlarged, of a pale gray color, the capsule readily detached. On section, nothing abnormal noticed with the exception of a cheesy patch of necrosis at the bottom of a scar seen upon the surface.

Bladder. Showed nothing abnormal.

Liver. Not particularly altered in size, was of a purple color; on section the lobules were distinct, the central portions unusually voluminous and of a reddish-brown color.

Stomach. Contracted, its mucous membrane thickened and opaque, besmeared with a moderate quantity of thick gray mucus.

Intestines. The small intestine showed nothing abnormal. In the lower part of the large intestine were numerous, slightly elevated opaque linear adherent patches surrounded by an injected margin.

Mesentery. In the mesentery were found a dark reddish-gray homogeneous nodule as large as a cherry.

PATHOLOGICAL DIAGNOSIS.

Chronic Aortic Endocarditis.
Valvular Disease.
Chronic Myocarditis.
Hypertrophy and Dilatation.
Acute Vegetative Endocarditis.

Embolism of { Coronary Artery. / Spleen. / Kidney.
Ischæmic Necrosis of { Spleen. / Kidney.
Aneurism of Mesenteric Artery.
Perinephritic Hæmatoma, — aneurismal (?).
Chronic Adhesive Pleurisy.
Desquamative Pneumonia.
Diphtheritic Colitis.

SYMPTOMS FOLLOWING INJURY TO THE HEAD AND BACK.[1]

BY E. S. BOLAND, M.D.

FEBRUARY 3, 1886, I was asked by an acquaintance to see his sister, who had been hurt seventeen months before by being thrown from the platform of a car, and falling some distance down an embankment. I was told that she had brought suit against the railroad company, and had won her suit, but the defendants had talked of appealing, so there was every prospect of delay and uncertainty as to compensation, with the added worry of attendance on court, medical examinations, and expense which they could ill afford.

The bearing of these facts on the case is evident. On calling, I found a large, fleshy woman, who seemed quite weak, not over communicative, evidently suffering, and possibly apathetic. She lay on a sofa in her room in a boarding-house, her right shoe was unbuttoned on account of the swelling of her foot, and her clothing exhaled a urinous smell — not ammoniacal. On being aroused and told who I was, by dint of questioning, the following history was obtained:

Age, forty-five. Born in Maine; married. Has one daughter, now sixteen years of age, and in vigorous health. The patient is one of a family consisting of three or four sisters and two brothers. With the exception of one sister, who was hurt at the same time with the patient, and another who has cancer, the family are healthy. Patient's father died about the age of fifty, of some acute disorder. Her mother is living and active, though eighty. One of her grandparents lived to be more than one hundred. Says she has always been strong and healthy. Menses began at seventeen, and were regular and painless. Says she left home, when quite young, to earn her own living, as her family were in reduced circumstances. Did housework in private families and hotels, worked as a factory-girl some, and later, since her marriage, as a seamstress at home at times. Tells me that she was never nervous, and never fainted but once, and gave an adequate reason for that. Has weighed one hundred and ninety pounds, and now cannot be far from one hundred and sixty pounds. Does not look like a nervous woman. After a year's acquaintance, I regard her as an honest, even-tempered, unambitious woman, strictly temperate, industrious, and willing to enjoy life as it comes. Education limited.

She tells me that in October, 1884, she was about to step from a railroad car, having reached her destination, when the train started up, and she fell, or was thrown, down an embankment, the car having already passed the outer end of the station-platform. Believes she struck on the right side of her head, and also on her back, and was stunned, but was able, with assistance, to walk to the omnibus, which took her to the house of her sister. She says she remembers nothing from the moment she found herself falling until three hours after, when she came to herself, and found herself in bed. Says the fall was about fifteen feet. Here she was seen by Dr. ——, who, in answer to some inquiries, favors me with this letter:

——, February 9, 1887.

DEAR DOCTOR,— Yours at hand. I saw Mrs. X. about 9.30 P. M., after the accident. She was not unconscious, but complained bitterly of pain in the side of her head, and in the lumbar region of back.

There was no scalp wound or contusion, but the back was quite severely bruised. Complained of headache and dizziness all of the time I cared for her. The back was better at times, but never wholly easy and painless during the six weeks. There was no rise of temperature.

She was confined to bed most of the time for six weeks, because of weakness of the back and inability to stand or sit erect, as it made her nauseated. Her stomach was rebellious, and very intractable to treatment. The bowels were irregular, and the stools were bloody and painful at times.

The urine was scanty, and loaded with phosphates and bile pigment, but contained no albumen or sugar. Menstruation was irregular and painful. Said she was always free from pain and regular before injury. Had some leucorrhœa; none before. There were no bed-sores. She complained a great deal of loss of vision and hearing; at times, stated that all objects were yellow, and at other times, black. At that time, she was very much jaundiced. Sometimes lower extremities were cold. I never felt for a moment that she was assuming any aches or pains for the benefits that she might derive from the railroad company. Her case, I think, was at the time, and since has been obscure in many respects, as far as I have been able to learn. I wish I were able to give you more facts, instead of the few that I have to offer.

I remain yours sincerely, —— ——.

P. S. Am sorry to say that I did not examine her uterus.

She says she remained here almost two months, most of which time was spent in bed, amid much suffering and generally deranged health. Wet and soiled herself at times, ate little, and, when she was able to sit up, she could not stand or walk without assistance. Going down to her home in Maine, she remained there about a year. In January, 1886, she came to Boston to attend to her suit against the railroad. While in Maine, she was under the care of a local practitioner. He treated her for her back pains locally, and gave more or less general treatment, but, she says, with little apparent benefit. Whether he recognized the general anæsthesia and impairment of the special senses is uncertain. During this year, she left her room but twice.

On returning to Boston, she was examined by experts, both for herself and the defendants. The two medical men under whose care she had been since the injury were also summoned. Just what was claimed or what was proven I have never learned, other than that she won her case. I was told the railroad company talked of carrying the case to another court, and rather than endure another trial, a compromise was finally affected at a smaller sum than the court awarded. She complained much of the circumstances of the examination by the experts, the excitement and efforts incident to the trial, and was, I believe, temporarily

[1] Read at a meeting of the Boston Medico-Psychological Society, March 17, 1887.

made worse by them. It was a few days later when I first saw her.

When, in February, 1886, she came under my care, she made the following statements to me:

That she has never been well since the injury, having changed from an active, healthy woman, who made her own living and enjoyed life well, to a comparatively helpless invalid. That her menses are irregular and painful. That she cannot see nor hear well, and cannot taste nor smell at all. Cannot feel heat, cold, nor touch. That her appetite has been very poor till lately, and that she has lost flesh. That she has and does suffer from irregular periodical pains in her back and head. That she occasionally has "bleeding from up in her head," which, when it occurs, as it usually does, at night, runs down her throat, to nauseate her when she awakes. That she sees double with her right eye, but not with her left. She further states, in answer to leading questions, that she has not sneezed, had hiccough, or a "natural headache" for months. That she cannot hold her urine well — must go at once, and wets her clothing when she coughs. Says she sleeps poorly, and thinks her memory is impaired. (Subsequent observation, in so far as memory for events since the injury goes, confirms this statement.) Says her hair has been turning since the injury, though it is still strong and abundant. Says she does not know where her hands or feet are. Has to *look* for her pocket, and cannot, with her eyes shut, tell when her hand touches her nose.

Together with one of our members, who saw her in consultation, I made the following observations:

Cutaneous Surface. Does not feel pricking or pinching her skin anywhere, except on the neck, upper eyelids, and lips. Does not feel pulling the hair on the scalp, legs, or eyebrows. Does not know that her feet are quite cold. Does not feel the direct current from a Gaiffe faradic battery at all, and can feel the induced current only on the neck, distribution of the left ulnar nerve, on the end of the nose, and on the right cheek, when the electrode is over a tooth with metallic filling.

Muscular System. Grasp quite weak in both hands. Muscular efforts all slow and feeble. Gets on her feet with apparent effort, and walks on the level floor in a very unsteady way, and then only by the help of a chair or somebody's help. Extension and flexion of the feet very slow and feeble. Cannot stand with eyes either open or shut, unless supported. No ankle clonus. Knee-jerk short and delayed. No muscular reaction to the faradic current, either direct or induced. (The galvanic current was not tried till later.)

Eyes. No ptosis, squint, or disorder of the muscular apparatus. Conjunctival injection to a slight amount after the tests, or much use of the eyes. Pupils equal, normal in size; react to accommodation, but not very energetically to light, as ophthalmoscopic examination is easily made without a mydriatic. Media clear; no gross change in papillæ or vessels. Field of vision somewhat diminished in left eye, and very much contracted in the right eye. Can read Snellen XX at two feet with left eye, and cannot name the letters at all at any distance with right eye. Sees two fingers at six inches as four, and one finger as two, in the right eye. Sees floating specks in right eye, but not in the left. Has never used glasses. Was conscious of no failure of sight, or unequal power of eyes, before her injury.

Taste. Cannot taste the fresh juice of a lemon on either side of her tongue, nor did she taste the solution of strychnia sulphate, though given $\frac{1}{15}$ gr. dose to the tablespoonful, until she had been under treatment for thirty-seven days. Says she does not relish her food, because she does not taste it.

Digestive Tract. Tongue slightly coated. Occasionally, vomiting after the pharangeal hæmorrhages. Bowels obstinately constipated.

Ears. Both ears normal as to meatus and drumhead. The left alone inflates (is felt to inflate) by Valsalva's method. Can hear the watch only while in contact with the right ear. Hears the watch at four inches in the left. Hears ordinary conversation without difficulty.

Olfactories. Cannot, in either nostril, smell orange or lemon peel, cologne, or chloroform liniment.

Bladder and Kidneys. Control over bladder imperfect. Urgent and intolerant when partly filled. Never retention. Urine increased in amount; acid, pale, clear; specific gravity, 1010. No bile, sugar, or albumen. No deviation from the normal constituents. Negative microscopically. Pulse 80 to 90, temperature normal. Heart and lungs sound. Fortunately, we were not urged for a diagnosis. A very uncertain prognosis was given, and only rational, energetic treatment promised.

Treatment. At the suggestion of the consultant, general faradization, blistering the upper dorsal spine, and compound syr. hypophosphites, with solution of sulphate of strychnia, was given, and persisted in, with some variations or additions, for about three months. One week after beginning treatment, massage was added to the other treatment. This was given once a day thoroughly, and usually repeated to some extent by her daughter in the evening. Occasionally, $\frac{1}{4}$ gr. morphine had to be given for the pains. Cathartics were used as needed. After six weeks' treatment, when, with returning feeling, pains began to be felt in the limbs, the constant current, from eighteen to twenty-four cells of a McIntosh galvanic battery, were used, on alternate days, with the faradic current.

Progress. I shall quote from the notes taken almost daily while under treatment:

February 13th. She began to feel the induced current over the anterior tibial nerves.

February 16th. Double vision disappeared from the right eye; otherwise, but little change in the special senses. Left hand the stronger and more sensitive. In fact, the entire left side was less severely affected, and began to improve sooner than the right.

March 10th. Much more muscular response to the induced current, and she feels it more. Sleeps poorly. Menses more prompt since the electrical treatment was begun. Neither massage nor electricity, however, seemed to help her constipation, and cathartics had to be given continuously.

March 14th. Combed her hair for the first time.

March 16th. Began to use a modified, combined chest-weight and rowing apparatus, which admitted of a stirrup movement. The first attempts were feeble and awkward. Up to this time, some active movements on her part had been comprised in the massage.

March 17th. Tasted the solution of strychnine for the first time to-day, the dose being about $\frac{1}{15}$ gr. in a tablespoonful of water.

March 22d. Was given special deep manipulations

over the great nerve-trunks. Can hear the watch one inch from her right ear. Grows more hopeful, as she begins to see improvement.

March 23d. The constant current used for the first time. Fair response on the left side, and some response on the right, on making and breaking the circuit. Feels deep manipulations over the median, sciatic, and perineal nerve-trunks. As the strychnine had now reached about $\frac{1}{4}$ gr. in all daily, some stiffness of the jaw was felt, and the amount reduced to $\frac{1}{10}$ gr. daily. Has got rid of the urinous smell, and does not now lose control of her bladder, except when she coughs.

March 25th. Can walk a little without support, and has attempted some light household work.

April 1st. Is doing well. Gains in strength and sensation.

April 5th. Felt that her left foot was cold to-day for the first time. Notices the smell of tobacco smoke and tastes and relishes her food. Felt her "head itch" to-day and can feel the compass points on the scalp, except for a space corresponding with the parietal bones, though not quite so wide from before backward.

April 11th. Complained of the blister over her dorsal spine — heretofore she has not felt the blistering. Abdomen still anæsthetic to touch, but feels the faradic current. Can hear the watch at four inches in the right ear. Reads Snellen XX at ten inches with right eye. Can go up and down stairs by the hand-rail and the use of her cane. Rides out, but is easily tired.

May 1st. Pharyngeal hæmorrhages recur every week or two. Sneezed to-day, the first time for many months, she says. Left side so much better, both as to motion and sensation, that from this time on most attention as to massage, electricity and exercise shall be given to the right side.

May 6th. Walked six squares to-day, by taking hold of her daughter's arm. Tired out, but none the less elated in consequence.

May 8th. Right ankle weak, and she begins to complain of pain in the region of the os calcis and up the tendo-Achilles. The space between the tendo-Achilles and ankle-joint is tender on pressure and pains when dorsal flexion of the foot is attempted. Prefers to walk on her right toes. Reads Snellen XX at twenty inches with right eye, and hears the watch at ten inches in right ear.

May 13th. Felt me tickle the sole of her left foot to-day for the first time. Has severe pains in her back, and being unwell suffered more than usual.

May 16th. Rode eighteen miles in a carriage to-day. Tired out.

May 18th. Can read Snellen XX at *six feet*, with right eye, and hears the watch in right ear at twelve inches.

May 21st. Walked six squares again yesterday. The right side of face, right hand and arm, right leg below the knee, and foot still below par as to strength and sensation. Cannot distinguish the compass points on right hand nearer than one and three-fourth inches except on ring and little finger. Can feel a single point quite distinctly. Right cheek and brow cannot feel the points nearer than one and one-half inches. Left side almost normal as to strength and sensation. Left sole ticklish but the ribs not ticklish. Does not feel distinctly on ribs near spine. Sight and hearing on left side normal.

At this date she left Boston for Maine, and the treatment which for the previous hundred days had been daily and as thorough as I could give, became imperfect or irregular. Shortly after she returned and settled near Boston. Since this time I saw her only at irregular intervals, going two or three times into the country, and treating her for three or four days at a time when she would come to Boston. Have not seen her since November 30, 1886. Ever since last summer the right ankle has been weak and painful and has not fully regained sensation. It has been treated by friction, electricity, elastic compression, bandaging, position, and more lately with a fixed dressing of silicate of potash; the latter being still in use and gives more relief than any other measure. There are still some back and head pains and an occasional pharyngeal hæmorrhage. Hydrastis, fluid extract ergot, iodide of potash and Fellow's syrup hypophosphites compound, have all been tried — the latter seeming to give the best results — probably from the contained quinine and strychnine. She has used a Hall's faradic battery at home, but probably not very efficiently. Sometimes after an interval an examination would not give as good a result as at a former period.

It is hardly necessary to refer to the diverse views held as to these cases of functional trouble following railroad injury. Though the literature is abundant, the pathology, so far as ascertained, is scanty and unsatisfactory.

To Erichsen probably, more than to any one else must we ascribe the credit — if credit it is — of having popularized the idea that grave and lasting injury may be sustained by the spinal cord from slight railroad and other accidents, which are not accompanied by visible injury. He says: "Not only do most serious, progressive, and persistent symptoms of concussion of the spinal cord often develop themselves after apparently slight injuries, but frequently when there is no sign whatever of external injury."

Ross takes practically the same ground and admits further that "violent mental excitement appears to be able to produce the symptoms of spinal concussion occasionally." Herbert W. Page, in his late book on "Injuries of the Spine and Spinal Cord," questions these positions, and argues for the existence of mechanical lesion somewhere in the cerebro-spinal axes, or surrounding structures, except in the cases where there is intentional fraud, or merely functional disturbance.

Dr. R. M. Hodges, in this country, has done much to bring about a vigorous skepticism of the views of Erichsen.

Was this a case of "railroad spine"? Remember it was not the result of a collision. It might have been due to a fall from a carriage, stairway or landing. As the car was just starting and the motion at most being at right angles to her fall it could not have given her much impetus. As the fall was less than sixteen feet, it would occupy a little less than a second. This would be about equal to ten miles an hour.

The case had this in common with ordinary collision accidents; namely, the liability of the railroad for damages. There was, therefore, the possibility of assumed or exaggerated injuries. This, I kept in mind and

tried to be impartial and discriminating. In favor of entire veracity were the facts that the suit had gone in her favor and there was less occasion for maintaining an assumed condition of invalidism. Besides, the examinations were distasteful and the treatment exacting and expensive. Still a clever and practised imposter could give the same results as to sight, hearing, muscular strength, smell, taste, pains, and to some extent to the electrical tests. The suppression of the normal response to the faradic current could not well be assumed, nor is it probable that the induced current could be taken on face and arms without the patient evincing suffering.

That she was severely injured, suffered much, improved under treatment and is still far from well, I believe as firmly as I do the Apostles' creed, but must confess I could as little prove one as the other by incontestable evidence. The fact that she made more improvement in three months following the settlement of her claim than in a year previous does not impugn her honesty. Who does not admit the therapeutic value of satisfaction and certainty? No doubt the electricity and massage were factors in her improvement.

Page says: "Even in perfectly genuine cases — and it is these to which we now refer — compensation acts as a potent element in retarding convalescence, as evidenced in numberless instances by the speed with which recovery sets in as soon as the settlement of pecuniary claim has been accomplished."

Dr. R. M. Hodges is more guarded: "Recovery or improvement of a fixed and permanent character, never takes place until after the adjustment of any existing claim for compensation; and so long as this is final it makes little difference whether the settlement is a favorable or unfavorable one for the claimant."

In this case is it probable that the seat of the injury was cerebral rather than spinal? In such cases, Gowers admits that such a condition is probable.

There was functional disorder of the spinal nerves as to motion and sensation, there was spontaneous pain and tenderness to deep pressure; but there was no complete paralysis, contracture or trophic change (unless the swelling of the right foot and ankle be so regarded), at most there was suspended action.

That the spinal column, with its seventy-two joints — not to mention the rib articulations — its complicated and various structures should endure such a fall without receiving some wrench, strain or fibrillary rupture does not seem probable; but that such wrench, strain or rupture induced trauma of the *cord* or led to hæmorrhagic pressure, or subsequent inflammatory changes is not shown by the clinical history. If any one will recall the situation of the spinal cord surrounded by the pia and suspended in the fluid-filled dural sheath and this loosely attached to the walls of the firm but flexible spinal canal it seems hard to believe that so small a mass of matter, so perfectly situated, could suffer from "vibratory jar," sufficient to induce molecular change. How different it is from the brain when there is great mass and little packing. As to the immediate visceral disturbances mentioned in the doctor's letter — vomiting, jaundice, intestinal hæmorrhages, etc. — we are not now concerned, though the vomiting might indicate head trouble. Injury to the cord in the cerebro-spinal region might explain the amblyopia, but how would any merely spinal lesion account for the auditory, olfactory, gustatory or trygeminal symptoms? The unilocular diplopia, which had every appearance of being genuine, must in the absence of apparent defect in the media be regarded as central.

If the trouble was cerebral, what and where was the lesion?

REPORT ON MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M.D.

ANILINE POISONING.

F. Muller[1] found free aniline in the urine of a person poisoned with aniline; the urine reduced Fehling's solution, but had no action on polarized light. Each 100 cc. of urine contained 4.75 mgrms. of free sulphuric acid, and 76.1 mgrms. of combined sulphuric acid. When a portion of the urine was boiled with concentrated hydrochloric acid, neutralized with sodium hydrate and shaken with ether, an ethereal extract was obtained, which gave, when tested, the blue indophenol reaction. The ether extract of the unboiled urine did not give this reaction; consequently the aniline must have been secreted as paramidophenyl sulphate. The striking resemblance which patients treated with acetanilide show to persons poisoned with aniline, led the author to compare the urine in the two cases. In both cases methæmoglobin was found in the blood. Aniline was not found in the urine after the ingestion of acetanilide, but the indophenol reaction was obtained. There was also a noticeable increase in the amount of combined sulphuric acid. From this the author concludes that acetanilide is separated from the system in the same form as aniline; namely, as paramidophenyl sulphate. The latter may be detected by boiling the urine a few moments with one-fourth its volume of concentrated hydrochloric acid, adding a few cubic centimetres of a three per cent. phenol solution, and then a few drops of a chromic acid solution. If paramidophenol is present, the liquid becomes red, and then changes to blue upon addition of ammonia.

COLCHICINE.

Experiments made by Mairet and Combemale[2] on dogs and cats, show that colchicine is an irritant poison which may act upon all the organs, but acts especially on the intestinal canal and kidneys. The minimum toxic dose is variable, according as it is administered hypodermically or introduced into the stomach. In the former case it is 0.571 milligram, in the latter 1.25 milligram for each kilogram weight of the animal experimented upon. Its effects are produced more rapidly when it is administered hypodermically. It is eliminated through different channels, but especially with the urine; but elimination is slow, and colchicine may therefore behave as a cumulative poison if administered in non-poisonous and relatively small doses at short intervals. Colchicine produces congestion at the articulations and in the marrow of the bones.

Experiments on men, dogs, and cats,[3] show that colchicine in therapeutic doses acts either as a diuretic or a purgative, according to the dose, and this action

[1] Chemisches Centralblatt, 1887, 8, page 193.
[2] Journal de Pharmacie et de Chimie, April, 1887, page 355.
[3] Ibid. p. 357.

is a result of irritation of the kidneys or alimentary canal. The therapeutic effects are the same, whether the drug is administered hypodermically or by the mouth; but the action is more rapid in the former case, and the dose necessary to produce the effect is less. Man is three times more sensitive to its action than are cats and dogs. A dose of two or three milligrams is sufficient to produce the diuretic action, and five milligrams the purgative action. Colchicine causes an increase in the amount of uric acid excreted.

ANTIDOTES TO STRYCHNINE, RESORCINE AND PICROTOXINE.

Professor Anrep [4] has proven experimentally that urethane possesses properties antagonistic to the convulsive drugs, such as strychnine, etc., and believes that urethane may be employed in cases of poisoning by these substances. It is superior for this purpose to hydrate of chloral; it is less dangerous, and may be administered in large doses with perfect safety. The author concludes that, in the case of man, it is necessary to administer it in doses of four to six grams as an antidote to the poisons above mentioned.

E. Koch [5] states that butylchloral hydrate is useless as an antidote in cases of strychnine-poisoning: in picrotoxine-poisoning, it fails to overcome three times the minimum fatal dose, behaving in this respect like chloral-hydrate. Picrotoxine may be successfully used as an antidote to the narcotic effects of butylchloral hydrate and chloral hydrate. According to A. Bockal [6] paraldehyde is a powerful antidote to strychnine. Ten times the fatal dose of strychnine may be safely administered to dogs that have previously received paraldehyde. Strychnine is not, however, an antidote to paraldehyde.

ESTIMATION OF STRYCHNINE AND BRUCINE.

Holst and Beckurts [7] have based a volumetric method on Dunstan and Short's observation that strychnine is completely precipitated from aqueous solution of its sulphate, whilst brucine is not. If a 0.5 to 1 per cent. solution of the two alkaloids, strongly acidified with hydrochloric acid, is treated with potassium ferrocyanide until a filtered portion of the solution gives a blue stain with ferric chloride paper, the whole of the strychnine is precipitated as acid strychnine ferrocyanide, whilst the brucine remains in solution.

The amount of strychnine can thus be determined by using a standard solution of ferrocyanide, 244 parts potassium ferrocyanide corresponding to 334 parts of strychnine. If the solution contain less than 0.5 per cent. the separation is too slow; also the ferric chloride paper should not be allowed to get perfectly dry before use. A mixture containing 0.145 gram strychnine and 0.036 gram brucine gave 0.148 gram of strychnine. To estimate the alkaloids when occurring together, the total weight of the two is ascertained, then, according to Schweissinger, an excess of centinormal hydrochloric acid is added and the excess determined by centinormal soda solution. The neutral solution thus obtained is concentrated sufficiently and titrated with standard potassium ferrocyanide. A mixture containing 0.1 gram strychnine, and 0.05 gram brucine gave 0.1017 of the former and 0.04915 of the latter.

THE ACTION OF TOBACCO.

Observations by Grammatschicow [8] and Ossendowski have led to the following conclusions: The assimilation of nitrogenous matter is lessened. Digestion is prolonged. The consumption of tobacco hastens the assimilation and elimination of potassium iodide. The influence of tobacco on the processes of nutrition and assimilation is especially noticeable in those just commencing its use.

Walitzkaja [9] has made an examination of more than one thousand workers (men, women and children) in tobacco, and has in addition undertaken a series of experiments on animals in the laboratory of Prof. Anrep. The workmen who are constantly exposed to an atmosphere filled with the powder of tobacco, suffered chiefly from nervous symptoms; such as dilatation of the pupils; cardiac neuroses; exaggerated tendon and vasomotor reflexes; trembling of the hands; dyspnœa. They are subject to headache, attacks of fainting, gastralgia, and cramps. Next to the nervous system the respiratory organs suffer most frequently. Bronchial and laryngeal catarrh and empysema of the lungs are common. Phthisis does not appear to be frequent.

Experiments upon dogs and rabbits clearly established the fact, that the nervous troubles observed in the workmen are really due to tobacco. The symptoms of poisoning are the same after injection of nicotine, as after exposure to an atmosphere impregnated with tobacco; and these symptoms are identical with those observed in workmen.

PHOSPHORUS.

Poleck [10] reports a case of phosphorus-poisoning, in which phosphorous acid was detected in the contents of the stomach and intestines, and in the heart, liver, kidneys, and brain, three months after death. No free phosphorus could be detected.

INFLUENCE OF POTASSIUM IODIDE UPON THE ELIMINATION OF MERCURY.

According to Dr. Souchow,[11] the elimination of mercury commences later, and the quantity eliminated is relatively less in those cases in which the patient takes potassium iodide in conjunction with the mercurial preparation. If the iodide is administered during or after the mercurial course, the quantity of mercury eliminated daily is lessened. The iodide, therefore, appears to prevent the elimination of mercury, instead of hastening it, as has been believed by some, and would seem to be useless in cases of mercurial poisoning.

TIN.

Ungar and Bodländer [12] have already proven by experiments on dogs and rabbits that tin may be absorbed and detected in the organs and urine of these animals. They have also detected it in the urine of man in two cases. They have now made experiments to determine whether any injury to health can result from the introduction of tin into the system. The experiments were made upon frogs, rabbits, and dogs, and the compounds employed were stannous chloride, the tartrate of tin and sodium, and the acetate of tintriethyl, administered in part by way of the stomach,

[11] Journal de Pharmacie et de Chimie, April, 1887, p. 367.
[12] Chemisches Centralblatt, 1887, p. 644.

in part by subcutaneous injection. The results show that the introduction into the system, even of non-corrosive tin-salts, will produce morbid symptoms, and finally, death; also, that very minute amounts repeatedly introduced into the system gradually undermine the health, and frequently result in death. Small doses of the acetate of tin-triethyl are far more poisonous than the tartrate of tin and sodium. This conclusion agrees with that reached by White, and suggests the fact that the action of the former compound is not due to the metal alone, but to the compound as a whole. The introduction of this compound into the system is followed, first, by a series of primary symptoms, quickly disappearing, due to the action of the compound as a whole, followed, after some days, by a train of symptoms due to the action of the metal. The results of the authors' experiments lead them to the conclusion that the question of the poisonous action of the tin compounds, aside from any local effect, must be answered in the affirmative.

SILVER-ABSORPTION IN PLATE-WORKERS.[13]

Observations made on eight hundred silver-workers in Berlin have shown that all of them had the characteristic patches of coloration. These patches are round or oval in shape, varying in size from a millet-seed to a broad bean. As a rule, they are not raised; they are anæsthetic, and occur principally on the dorsum of the left hand. Only workers in silver are thus affected, and not those who manipulate gold or copper. The absorption of the metal seems to have no effect on the general health. Microscopical examination shows that the patches are caused by the deposit of metallic silver in the tissues, and they are soluble in nitric acid and potassium cyanide. It was noticed that the men affected were invariably those who had some ulceration or abrasion of the hands, through which the metal was absorbed. The nature and shape of the metallic deposit warrants the supposition that the metal enters in a soluble form, and is then precipitated. Three workmen who were being treated for syphilis with mercury developed a number of fresh stains in a comparatively short space of time.

THE FATE OF CERTAIN CHLORINE COMPOUNDS IN THE ORGANISM.

A. Kast[14] first gives some hitherto unpublished results of Mylius, showing the influence of the administration of chloroform on the amount of chlorine in the urine of the dog, from which it appears that the administration of chloroform is followed by a great increase of sodium chloride in the next day's urine. Kast has now pursued this research further. The effect of the inhalation of chloroform was first tried on a dog, and the increase of chlorides was found to be very marked after chloroform narcosis, whilst ether produces no effect. A similar result was obtained in experiments on man. Chloral was next investigated, and it was found to have no such effect in producing an increase in the chlorides of the urine; this substance leaves the body as urochloralic acid, and does not part with its chlorine. Similar investigations with carbon tetrachloride, methyl chloride, and ethyl dichloracetate also gave negative results; but ethyl trichloracetate, on the other hand, produced a very decided increase in the output of chlorides.

SUGAR-REACTIONS.

With reference to the new reactions for sugar described by Molisch, D. Lindo[15] has found that a one per cent. starch or gum solution gives the reaction with thymol, as does also one part of cane-sugar in 200,000 of distilled water, and that all samples of normal human urine do so also, even when diluted with fifty volumes of water. He considers, however, that this fails to prove the presence of sugar in normal urine, which, as a complex fluid, must be acted on by the sulphuric acid. He finds that nitrates give the same characteristic color reactions and precipitates on dilution, and that similar results are obtained when menthol is substituted for thymol; menthol has also the advantage of not giving with nitrates or nitrites any reaction that could be mistaken for that of sugar. Chlorides or hydrochloric acid do not impair the delicacy of either test, but sugar cannot be detected by either, in the presence of notable quantities of nitrates or nitrites.

PECULIAR MODIFICATION OF UROBILIN.

Salkowski[16] has met with a urine which was extraordinarily rich in urobilin, but from which the urobilin completely disappeared after standing in a flask for some months, the urine, however, undergoing no perceptible change in color. The change did not depend upon alkaline fermentation of the urine, and micro-organisms apparently had nothing to do with it.

Urobilin is a body very easily decomposed, and it passes over, gradually upon standing, quickly upon heating, into a modification which is still colored, but which shows no absorption bands, which does not fluoresce in alkaline solution with zinc chloride, and which is not removed from acid alcoholic solution on shaking with chloroform.

It appears probable that those dark-yellow or brownish-yellow urines, which apparently contain urobilin, but in which neither urobilin (except, perhaps, in traces), hæmoglobin, methæmoglobin, nor biliary coloring matters can be detected, contain this decomposition product of urobilin. The author thinks it possible that most normal urines contain, together with urobilin, this modification of urobilin.

NEW PATHOLOGICAL URINARY COLORING MATTER.

Leube[17] reports the case of a patient suffering from osteo-malacia, cystitis, and nephritis, whose urine assumed a dark violet to black color on being exposed to the air. The coloring matter is amorphous, and soluble in ether, and can be extracted from the ethereal solution by dilute alkalies, but not by acids. The alkaline solution is, at first, brownish-red, later, yellow. The coloring matter is soluble in hot water, chloroform, benzol, and alcohol; the alkaline solution is decolorized by zinc-dust, and regains its color upon subsequent exposure to the air. Its solutions are not fluorescent, and do not show any characteristic absorption bands.

NEW NORMAL URINARY COLORING MATTER.

According to Giacosa,[18] the chromogen of a new urinary coloring matter occurs normally in the urine of man, dogs, and rabbits, from which it can be ex-

[17] Archiv der Pharmacie, 1887, p. 784.
[18] Archiv der Pharmacie, 1887, p. 785.

tracted by amyl alcohol, and precipitated in great part by basic lead acetate. Its solutions show no absorption bands, thus differing from solutions of the uroroscin of Neucki and Sieber. Solutions in ether and in chloroform show a beautiful green fluorescence; a solution in amyl alcohol is weakly fluorescent, one in ethyl alcohol not at all. A process is given for the extraction of this coloring matter from the urine.

CHANGES EFFECTED IN THE URINE BY A MILK DIET.

According to Chibret,[19] the amount of urea excreted daily is very largely increased under the influence of a milk diet. When the milk diet replaced wholly the ordinary mixed diet, the increase amounted to sixty per cent.; when the milk formed only a part of the diet, the increase amounted to thirty-five per cent. These statements are based upon the daily estimation of the urea excreted by two patients before, during, and after a milk diet of two months' duration, and a comparison of these results with those obtained from the urine of a person in health. As one of the patients, who was somewhat obese, lost flesh, while the other, who was thin, increased in weight, and the same results were obtained in the two cases, it is evident that the increase in the excretion of urea was not caused by denutrition.

C. Méhu [20] has frequently detected sugar in the urine of patients with albuminuria, who had been kept on a milk diet for a longer or shorter period. The quantity of sugar was ordinarily so small as to be easily overlooked in applying the ordinary Fehling's test. The amount present did not, as a rule, exceed 0.2 per cent., and only rarely amounted to 0.4 per cent. When the milk diet was suspended, the sugar gradually disappeared.

Similar results were obtained in scarlet-fever patients with or without albumin in the urine. In those cases in which the largest amount of sugar was detected, the urine was passed in small quantity, and was rich in urea and mineral salts, although, ordinarily, a milk diet tends to increase the amount of urine. The author has not determined whether the variety of sugar present was glucose or lactose. He has estimated it as glucose.

The author considers that the presence of a notable quantity of sugar in the urine of scarlet-fever patients is possibly an indication that the kidneys have not as yet regained their normal physiological power.

Clinical Memorandum.

A CASE OF ACUTE LOBAR PNEUMONIA WITH PROTRACTED FIRST STAGE.

BY J. D. JONES, M.D., UTICA, N. Y.

Benjamin J., aged twenty-two, of good constitution, but a hard drinker, was in his usual health up to September 28, 1887, when he had a severe chill. He was so ill that he kept his bed, but did not call a doctor till October 2d. He was then complaining of headache, a slight cough and vomiting. His pulse was 120; temperature, 104.5°; Respiration normal. Pneumonia was suspected, but physical examination of the lungs revealed nothing abnormal. His bowels were loose, owing to some "opening medicine" he had taken. Gurgling was obtained in the right ileo-cæcal region — a sign found in looseness of the bowels from any cause. He was given some antipyrine to reduce his temperature.

October 3d. A. M. Pulse, 102; Temperature, 102.5°; Respiration normal. Headache, cough and persistent vomiting. P. M. Temperature, 103.5°; other symptoms the same as in the morning. As six days had now elapsed since the chill, and physical examination of the chest revealed nothing abnormal, and owing to the prevalence of typhoid fever in the city, the case was reported to the board of health as one of that disease.

October 4th. He was delirious last night and to-day he complained of severe stitch in his right side. Severe epistaxis. A. M. Pulse, 102; Temperature, 102°; Respiration, 32. P. M. Pulse, 104; Temperature 103.75°; Respiration 32. A crepitant râle was heard over the lower lobe of the right lung posteriorly.

October 5th. A. M. Pulse, 108; Temperature, 103.5°; Respiration, 48. The physical signs of consolidation were heard over the posterior aspect of the right lung.

October 6th. The whole of the right lung is now consolidated. It will not be necessary to give the details of pulse, temperature, respiration, etc., the case pursuing the usual course of a severe pneumonia with active delirium throughout, and ending fatally October 14th, ten days after the crepitant râle was heard, and seventeen days after the chill.

Dr. Wilson Fox, in his article on "Pneumonia" in "Reynolds System of Medicine." says, "Rigors may precede by a period of from twelve to twenty-four hours, or even in some cases, of from three to four days, all other symptoms and local signs of pneumonia with the exception of pyrexia." Other authorities give three to four days as the extreme duration of the stage of engorgement.

I report this case lest others may be misled by their text-books on this point — and, possibly, to spare them the humiliation of having reported as typhoid fever, what subsequent events proved to be a case of acute primary pneumonia.

[19] Journal de Pharmacie et de Chimie, September 15, 1887, p. 275.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

C. P. STRONG, M.D., SECRETARY.

Meeting October 3, 1887, Dr. J. W. Swift in the chair.

Dr. Blodgett showed the organs from an autopsy which had been made on the day of the meeting.

The case was one of carcinoma, which was peculiar in the seat of its primary development, it having arisen from the cicatrix in the centre of the umbilicus.

The umbilicus presented the appearance of being much enlarged, and protruded about one centimeter beyond the level of the surrounding skin. Its centre was the seat of a loss of substance by ulceration, by which a cavity had been formed, about one centimeter in depth, and the same in diameter.

The panniculus adiposus was remarkably developed, the layer of abdominal fat being more than an inch in

thickness. The peritoneum was thickened and brawny, so that it resembled a fascia much more than a serous membrane. On opening the cavity of the abdomen, the omentum was found to be thickened to a most surprising degree, and to be of very hard and resisting character, so that it formed an unyielding capsule over the organs concealed beneath. The peritoneum was adherent to the omentum, and this to the viscera, so that the entire contents of the abdominal cavity formed a single agglomerated mass, in which little could be distinguished, and still less could be separated. The parietal surface of the peritoneum was much thickened, its texture changed to a mass of elevated, hard nodules, some of which were in a state of softening, and others were firmly attached to neighboring parts, which lay in apposition to them. The adhesions were most numerous and strong in the right hypogastrium, where the intestine, both in its ilium and colon divisions, was entirely obscured by the mass of firmly adherent and enormously developed new tissue. At other parts of the intestinal canal, there were isolated nodules of disease, from extension of the cancerous disease into these structures.

The cancerous disease had ascended towards the right hypochondrium, and had enveloped the pyloric end of the stomach by a dense and undistinguishable mass of firm tissue, in which the duodenum could not be traced, and which was attached to the neighboring portion of the liver. There were several large nodules in the substance of the liver, and some of these were already in a commencing stage of softening; they were situated mostly in the extreme right portion of the organ, although one isolated nodule was located in the apex of the elongated left lobe of the liver, which was lying in close proximity to the spleen. The stomach was the seat of invasion of the malignant process, and, in one place, it was so softened that the tissues were torn, even by the most careful manipulation, while being removed from the body. At the pylorus was a firm and dense infiltration of the gastric tissues, by which the lumen of that orifice was much reduced, and, at one point, the disease had perforated the mucous membrane, and appeared as a rounded prominence in the interior of the canal. The spleen presented a distinct nodule of cancerous nature upon its upper border, where it was much softened, and easily broke down. The entire organ was smaller than usual, and seemed to be in a state of moderate cirrhosis. There was no noticeable infiltration of the mesenteric glands, nor did the disease anywhere pass through the diaphragm. The kidneys were not invaded, nor were the organs of generation noticeably diseased. The cancerous infection of the organs within the abdomen seems to have proceeded by contiguity from one point to another, rather than by general infection through the lymph or the vascular channels, unless the invasion of the liver may be thought to have resulted from the emigration of portions of the diseased tissues from some part of the domain of the portal circulation in the mesentery, where there were numerous centres of disease, which had in some places undergone softening. There was no enlargement of the axillary, inguinal, or other superficial glands, or any appearance of further metastasis of the disease. The head was not examined.

Dr. Porter inquired as to any possible cause of irritation, or the existence of any previous ulceration.

Dr. Blodgett replied that there was nothing ever noticed previous to the uncertain existence of a "lump." The daughter is said to be subject to transient attacks of an erysipelatous character, and the mother the same, but the speaker knew nothing as to the nature of them.

Dr. Porter asked if the peritonitis was general cancerous peritonitis.

Dr. Blodgett said it was, and that its development could be well traced through the influence of gravitation. There was one symptom which the speaker had not infrequently noticed in cases of malignant disease; namely, increased susceptibility to high temperature, although, by the thermometer, the patient's temperature showed no elevation.

Dr. Kingman read a paper upon

ANÆSTHESIA IN NORMAL LABOR.—SECOND PAPER.

Dr. Blodgett condemned the use of the saturated ether sponge, because he had seen several cases of ether habit arising in this way. He had, personally, had very satisfactory results from the use of cocaine, which diminished the pain, and made the patient comfortable, simply by introducing a solution from time to time into the vagina during labor.

Dr. Dunn said that he had an antipathy to ether, and had but once employed it in a normal case. In every case in which he had had a post-partum hæmorrhage, ether had been used.

Dr. Strong said that the arguments advanced in the paper were not such as to induce him to abandon the use of chloral in the first stage of labor for ether. He thought the unsatisfactory results which were sometimes reached with chloral were attributable, not to the drug itself, but to its improper administration. To secure the best results, the medical attendant should not direct the nurse to give small doses of ten grains or so at intervals of thirty or forty minutes, as is quite customary, but, beginning with a full dose of fifteen to twenty grains, should remain with the patient, and administer one, two, or more doses of the same amount, at intervals of twenty minutes, thus securing a full physiological action of the drug. In the speaker's experience, there are no strictly normal cases where the treatment has not proven perfectly satisfactory. Of course, in cases where there is an extremely rigid os, neither chloral nor small doses of ether will prove sufficient, but complete surgical anæsthesia is demanded. The speaker took decided grounds against those who claimed that ether induced post-partum hæmorrhage.

Dr. Kingman, in closing the discussion, asked concerning the method of applying cocaine, and then explained that he had omitted the drug from consideration in his paper because it did not seem to him of sufficient value, in labor, to come in competition with the anæsthetics mentioned. He had never used it, as he had seen no really favorable reports of its action, and doubted its ability to relieve the highly complex pains of parturition.

Referring to the remark of one of the members to the effect that, in a large obstetric practice, he had gotten along very comfortably without ether, the speaker questioned whether the patients had fared so comfortably, and urged with warmth the consideration in this matter of the question of humanity. "True our grandmothers bore children without ether, and so they did without antiseptics, or even true cleanliness, but they died by hundreds of septicæmia. We have

offered women immunity from that dread disease, and hold in our hands the means whereby we can relieve their pain. Shall we refuse to use it simply because, so far, some have gotten along without it?"

DR. E. N. WHITTIER then read a paper upon

MESENTERIC ANEURISM.[1]

BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

PHILIP COOMBS KNAPP, M.D., SECRETARY.

MARCH 17, 1887. DR. H. R. STEDMAN in the Chair.

DR. E. S. BOLAND read a paper,

SYMPTOMS FOLLOWING INJURIES TO THE HEAD AND BACK.[1]

DR. KNAPP said that he saw the case in consultation in February, 1886, and at that time he made a provisional diagnosis of hysteria, giving a rather favorable prognosis. Further consideration of the case had led him to reconsider his diagnosis and to give a bad prognosis. The pupillary symptoms, the loss of control over the sphincters of the bladder and rectum, and the loss of electrical excitability in the muscles were not symptoms that could be produced by hysteria, but they pointed unmistakably to some structural change. He had had an opportunity of late to study many cases of nervous disease produced by injury occurring in the ordinary occupations of life, where there was no disturbing element of damages to complicate matters, and, in his experience, hysteria was a very rare result of such injuries. Neurasthenia was commoner, but still rare. Moreover, he thought that the favorable prognosis sometimes given in hysteria or neurasthenia of traumatic origin was a mistake. He saw no reason why the prognosis should be better than it is in idiopathic cases; and, in fact, he had seen cases of hysteria and neurasthenia where the symptoms had persisted for twenty years after the injury.

DR. FISHER said that we get genuine nervous symptoms in "railway spine," from concussion of the brain and cord, but the lesion was still unknown. Of course there was room for fraud; yet one case that he saw eighteen years ago, remained an invalid for years. Another case, where there may have been exaggeration, but not entire deception, was awarded $35,000 damages, and soon after recovered so as to be able to walk about with a plaster jacket. The symptoms were not always proportionate to the injury. A patient simply sat down on the ice, and now, four years later, is helpless and somewhat demented. He had once saved a road from damages by proving a previous hysteria. Most cases were without doubt genuine, some being functional and others organic.

DR. COWLES said that we saw all degrees of disturbance from slight causes, even from minor injuries. It was hard to differentiate the cases, for, as there is room for fraud, even genuine cases may be doubted.

DR. BULLARD said that in a large number of the cases that he had seen there was very little reason for simulation. In many cases the trouble lasted a long time, and sometimes they never recovered. Many cases, which are apparently functional, last a long time after any reason for simulation had passed away. A case of brachial paralysis, with reaction of degeneration in the muscles of the shoulder, had also hemianæsthesia. The symptoms were present three months after the trial, since which time the patient had disappeared. Here there was no deception. Great caution was necessary, but many persons who are injured find it hard to prove it.

DR. C. F. FOLSOM said that there was a certain group of symptoms which justified the diagnosis of organic disease, but there was no group of symptoms which justified us in excluding it. Hysteria is often a symptom of organic disease. Simulation is often practised, and is hard to exclude. He cited a case where four men of great experience in such cases testified in a patient's favor, the patient in consequence getting a verdict of $1,500. In a fortnight after, the man was well. A shaking up may cause a pure insanity, — a mild, affective functional trouble which may go on for years. Some patients get well in a few years, but they don't realize the fact until they get a sudden stimulus, such as the mind-cure. The commonest class of cases is called "hysteria," — a doubtful diagnosis. Very few of them recover completely, and in some of the worst cases there is no question of damages. One man had all the symptoms of "railway spine," after a highway robbery. He could not work for four years, and he is not well yet. In such cases, as Westphal thinks, there are probably minute patches of sclerosis. Hysteria is very rare. There is probably a slight injury, with degeneration of isolated cells, causing no exact symptoms, yet interfering with the general physical and mental health. A confident diagnosis of hysteria is unjustifiable.

DR. J. B. AYER said that the therapeutic value of settlement was marked. A man was struck by a horse-car, receiving various injuries which gave him a good claim upon the company. He stayed in bed, and it was hard work to get him out of bed. The claim was settled, and he improved so as to walk about, but some weeks later he was seen again on crutches, because he thought he had another claim against the city! On being convinced that he had no further claim he abandoned his crutches.

THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, October 20, 1887.

DR. CLINTON WAGNER read a paper on

COLORADO SPRINGS AND DAVOS-PLATZ COMPARED AS WINTER HEALTH RESORTS.

Dr. Herman Weber, he believed, was the first to recommend high, dry altitudes for patients suffering from phthisis. Not long since, warmth and equability were considered the essentials for a climate adapted to this class of cases, and many physicians were still of the same opinion; but the change that had taken place in the minds of a considerable proportion of the profession was forcibly shown in the popularity of such resorts as Davos and Colorado Springs, at one of which there was snow on the ground fully half the year, and at the other of which there was sometimes a difference of 130 degrees Fahrenheit between the day and night temperature. There was, in fact, no section of country in the world which combined warmth and equability with dryness. Dr. Denison, of Colorado,

[1] See page 450 of the Journal

[1] See page 446 of the Journal.

in one of his valuable papers had said that variability was characteristic of dryness, and equability was found only associated with dampness.

Dr. Wagner said that he could speak of both Colorado Springs and Davos from his own personal observations while residing at these resorts. Colorado Springs was at an elevation of more than 6,000 feet above the level of the sea, and five miles to the west of it was Pike's Peak, over 14,000 feet in height. It had the dryness of an inland desert, the climate was exhilarating, the atmosphere more clear than that of Italy, and its scenery compared with that of Switzerland. From September to the latter part of April or first of May there was no rain. There were no fogs or mists, and while snow occasionally fell, it rapidly disappeared. The sun shone for 330 days in the year, and in the sun the temperature was warm — 90 to 130 degrees. There was always at least 50 degrees between the temperature of the sun and shade. If the atmosphere were not cold and dry, the heat of the sun would be unbearable. Sometimes at night the thermometer fell considerably below zero.

One great advantage of Colorado Springs was that the invalid could be so constantly out of doors. The wind was the most disagreeable feature of the place, and this was worst in the months of November and March. On the whole, however, there was less wind than in the resorts of the Riviera. In pulmonary diseases the results were excellent, and cases with tuberculous cavities had been reported as cured. Nervous and irritable patients, with a tendency to vascular excitation, should never be sent to Colorado Springs, as the climate was too stimulating for individuals of this class. From all that he could learn, this resort was not contra-indicated in laryngeal phthisis, provided the patient were improving in other respects. He had seen one case of this kind cured, and one other that was improved and on a fair way to recovery.

The hotels and boarding-houses were excellent, and good furnished houses, provided with all the modern conveniences, could be secured at reasonable rates. There are fine churches, schools, libraries, a theatre and a club. The society was excellent, and there were plenty of horses, which could be bought or hired cheap; so that riding and driving constituted a conspicuous feature of the life there. Moreover, the accessibility of the place was a great recommendation to Americans.

Davos was an Alpine valley in Switzerland, 5,300 feet above the level of the sea, and protected from the winds by high ranges. The climate in many respects resembled that of Colorado Springs, although the temperature in the shade averaged lower — from zero to 25 degrees. The north wind was thoroughly exhilarating and bracing, but the south wind was enervating, damp and disagreeable. When the snow melted the atmosphere was naturally full of humidity. The snow usually lasted from the latter part of October to the early part of April. The invalid's day was very short, lasting only from ten to three. So far as his observations went, any serious cases did not recover at Davos, and he thought it was a resort better suited to patients with incipient phthisis and those who retained a certain amount of robustness. The air was entirely too cold to sit out of doors when there was no sun.

There were certain points of difference between the two places, and there could be no doubt that the advantage was on the side of Colorado Springs. Thus, while at the latter there was an average of twenty-eight good days in the month, at Davos there was only twenty. At Colorado Springs there were eight hours of sunshine in the day; at Davos, four and one-half. At Colorado Springs the invalid could engage in riding, driving, tennis, picnics, etc.; while at Davos the out-door diversions were confined to skating and tobogganing, which involved too violent exercise for many patients. At Colorado Springs the invalid could enjoy the comforts and advantages of home-life; while at Davos he was compelled to stay in a hotel, and it was well known that hotels frequented by many phthisical patients always partook more or less of the character of hospitals and were depressing in their influence. At Colorado Springs the patient could remain throughout the year; but at Davos he was obliged to leave early in the Spring, on account of the dampness from the melting snow.

At Davos the hotels were excellent, and there was plenty of amusement. Formerly the drainage of the place had been very defective; but within the last few years a most efficient system of drainage (said to be the best in Europe), had been introduced. As much could not be said for Colorado Springs, where there was no public system of sewerage whatever, and cesspools and old-fashioned privies were still in use. He understood, however, that a complete system was now in contemplation, and with the natural facilities of the place for good drainage, he had no doubt that it could be made very perfect. On the whole, he would say that while Davos was unquestionably the best high altitude health resort in Europe, the advantages of Colorado Springs were greatly superior in many respects.

Moreover, there were at Manitou conditions very similar to those at Davos, although it was at an altitude of more than a thousand feet greater, and the shortest days for the invalid was six hours in length. It was well sheltered from the winds, and also possessed some excellent mineral springs. At present, however, it was comparatively deserted in the winter.

DISCUSSION.

Dr. Alfred L. Loomis said that the climatic treatment of phthisis was constantly being regarded with more and more favor, and deservedly so. Eighteen years ago he had read a paper before the American Medical Association, in which he took the ground that it was wrong to send patients to warm climates, because a stimulating air was required in order to enable the patient to take out-door exercise. From his studies in connection with this subject since that time he had arrived at certain definite conclusions. In the first place, he did not believe that there was any locality which was *par excellence* the place for phthisical patients; but he recognized that two things were absolutely essential for a curative effect to be produced.

The first was a pure atmosphere, an aseptic atmosphere, if one chose to call it so. Pure air could be taken into the lungs on the same principle that antiseptics were employed in external disease and in surgical cases. He did not think it was possible to treat tuberculous cavities with antiseptic solutions, and doubted whether inhalations or other forms of applying antiseptic agents had any real effect upon the lungs. But if we could keep these organs constantly bathed in an aseptic atmosphere, we were doing all

that was in our power to arrest the disease. Under the beneficial influences of such an air the temperature was reduced and distressing nervous symptoms were relieved. This element, therefore, must be sought for in whatever locality was selected for the patient. Purity of atmosphere was naturally to be expected in high altitudes; but the number of inhabitants and various other circumstances might cause its contamination to a greater or less extent. He had no doubt that the air of Colorado Springs and Davos was originally aseptic; but since they had become crowded with hotels and consumptives, he feared that this was no longer the case, and he believed that the benefit of residing at these places would grow less and less until they would finally be altogether abandoned as health resorts.

The second essential for a curative effect was the presence of conditions conducive to the pursuit of out-door life. It was simply folly, he thought, for a phthisical patient to go to any resort and spend twenty hours out of the twenty-four shut up in a hotel or boarding-house. It was much better to remain at home; and if the patient was not well enough to take out-door exercise, he was not well enough to be sent to these places. This was why those in the first stage of phthisis were so often relieved; and the reason that those with cavities lived was because they went to the health resort in a condition rendering them able to live out-of-doors. It was, however, not necessary to go to Colorado to find a pure air, and besides, he did not believe that high altitude of itself was of the slightest practical importance. The great desideratum was purity of atmosphere; but as it was desirable that the patient should spend as much time as possible in the sun, Colorado Springs was to be preferred to Davos. As regards recovery in these places, if the patient did not remain in them for two or three years after all trouble had disappeared, the disease was almost certain to re-develop within a few months. This was the great objection to high altitudes for consumptives, and he thought it possible to secure a perfectly pure air at a lower altitude, and that, too, much nearer home.

DR. RUFUS P. LINCOLN said that he agreed with Dr. Wagner in believing that Colorado Springs was superior to Davos, and chief among its advantages over the latter was the larger amount of sunshine met with there. With the sun there was dryness; so that we would naturally look for the best results there. On the first of January at Davos, there was sun for only four hours and fifty-seven minutes; while at Colorado Springs, at the same date, there was sun for over nine hours, or nearly twice as long. There was also much less moisture in the air at Colorado Springs than at Davos. As to the advisability of sending a patient with laryngeal phthisis to high altitudes, there had been of late a considerable change in professional opinion, and Dr. Solly, of Colorado Springs, had told him that he had known three cases to recover at that resort.

DR. BEVERLY ROBINSON, who had been announced to take part in the discussion, but was unable to be present, sent a letter expressing his views, in which he stated that he could not say as much of any health resort in this country or in Europe as of Colorado Springs. A residence there, he thought, was of special benefit in the first stage of phthisis, and patients could there breathe the aseptic air to be obtained only at high altitudes; while the remarkable prevalence of sunshine enabled them to pursue the out-door life which was so important a desideratum.

DR. KRETSCHMAR said that Dr. Wagner was mistaken in supposing that Dr. Herman Weber was the first to call attention to the efficacy of high altitudes in phthisis, as the first one to do this was Dr. Bremer, who did so in a work entitled, "The Curability of Phthisis Pulmonalis," which was published in 1852. He thought that Dr. Loomis was in error in supposing that the aseptic character of the atmosphere necessarily underwent a change in such health resorts as those referred to, as the statistics showed that before the year 1853, when Dr. Bremer established his famous hospital at Gerberstoff, there were actually a greater proportion of deaths from phthisis in the place than there had been since, although more than 13,000 patients had been treated in it. It was also a fact that none of the Sisters who acted as nurses or other attendants in the institution had contracted the disease.

As regards Davos, Dr. Wagner was mistaken in his statement that there were no accommodations to be had except in hotels. There was no dust, which was an objection to Colorado Springs, and the snow unquestionably was of service in helping to preserve the aseptic condition of the atmosphere. In the spring, when the snow melted, the patients very properly left. The most serious drawback that Davos had as a resort for consumptives was the admixture of pleasure-seekers and invalids, since the latter were tempted to indulge in habits which were injurious to them.

The PRESIDENT, DR. A. JACOBI, said that while certain places had a considerable immunity from phthisis, this immunity was only relative. While it might exist among the agricultural population, this would not be the case among those who engaged in in-door employment. One element claimed as an important one in the climatic treatment of phthisis had not been referred to this evening, and that was the necessity of ozone in the atmosphere. This was supposed to be due to sunlight, and it was found among mountains and evergreen forests, as well as near and on the sea. As to the immunity of the nurses and other attendants in Dr. Bremer's hospital, he understood that in this institution it was claimed that the air in the rooms was completely changed five times every hour.

DR. LOOMIS referred to the beneficial effect of antiseptic emanations, and said that many places which were not naturally aseptic were rendered so by such emanations, especially those from evergreen forests.

DR. WAGNER said that he saw no reason why a patient should not be taken to Colorado Springs, even if he were not able to take exercise. The journey could now be made with comfort in a comparatively few hours, and when he arrived he could sit or ride out in the open air, which was not the case at Davos.

Recent Literature.

A Practical Treatise on the Diseases of the Hair and Scalp. By GEORGE THOMAS JACKSON, M.D. New York: E. B. Treat. 1887.

This book is a compiled treatise upon the diseases which affect the hair and scalp. It is in two parts.

The first part, consisting of 59 pages, is given up to a consideration of the anatomy, physiology, and hygiene of the hair; while the second part, comprising 267 pages, is devoted to its pathology, and to the treatment of its diseases. A very complete and painstaking catalogue of the literature which has appeared upon the subject since the year 1860, closes a book which, presenting, as it does, in one volume, a carefully made collection of the existing knowledge and opinions upon diseases of the hair and scalp, will be found useful by those seeking information upon these subjects. G. H. T.

The Modern Treatment of Disease by the System of Massage. By Thomas Stretch Dowse, M.D., F.R.C.P. London: Griffith, Farran & Co. Boston: Cupples & Hurd.

Dr. Dowse's book consists of three lectures on massage which were delivered before the School of Massage and Electricity at the West End Hospital for Nervous Diseases. With the exception of a little elementary anatomy and physiology in the first lecture, they are better adapted to the understanding of advanced students and practitioners rather than to that of those whom it is proposed to turn into skilled manipulators in less time than it takes to ripen pears. The clinical portions of these lectures are well worth reading, but the method of doing massage must be more primitive than that which was practised in the days of Hippocrates. The first principle of common sense in *masséing* is utterly disregarded; namely, to apply as much as possible of the hands and fingers to the surface to be *masséed*. Just imagine any one drawing his knuckles over a patient and making a return stroke with the wrist! The whole palmar aspect of the hands and fingers is thus rendered useless, which could otherwise do much more efficacious, agreeable and economical work. Dowse has it that when both hands are employed in *pétrissage* they should move simultaneously in the same direction, while Murrell thinks they should move simultaneously in opposite directions, but in our opinion they should more often be made to work alternately in the same or opposite directions.

It is a great satisfaction to see an author so thoroughly familiar with the normal and pathological conditions of the nervous system as Dr. Dowse seems to be, and it is evident from this that he feels quite competent to evolve from his inner consciousness all that is necessary to know and to do about massage, with little or no regard to what any one else may have said or done. But we fear that his enthusiasm has occasionally carried him too far, as when he says, "if this sympathetic nerve of the neck were massaged (*sic*) and brought into healthy action, the eye doctor, the ear doctor, and the throat doctor would have comparatively little to do, and the spectacle maker would have to find some new occupation." Kneading dough and lemons teaches nothing about massage on living tissues. What does he mean by imparting energy by massage? His wood-cuts are as useful as if they represented the man who took the measure of a barn-door between his hands, for neither patient nor barn-door is included between the hands.

Amongst the few authors referred to in the index is Oliver Wendell Holmes. We should like to hear Holmes on massage. But it is not about this that he is spoken of by Dowse. D. G.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 10, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 Boylston Street, Boston, Mass.

A SECOND GASTROTOMY FOR THE REMOVAL OF A FOREIGN BODY FROM THE ŒSOPHAGUS.

It was the privilege of the readers of the Journal last December, to read an account of an operation, at once original and successful, by Dr. M. H. Richardson, for the removal of a foreign body from the lower end of the œsophagus, where it had resisted attempts to dislodge it from above and was too low to be reached by an œsophagotomy. Dr. Richardson opened the stomach by an incision parallel with the border of the ribs, inserted the hand and forearm into the stomach, introduced two fingers into the œsophagus and drew the foreign body — a dental plate with false teeth — into and then out of, the stomach.

A second gastrotomy for a foreign body[1], this time a peach-stone, has just been published by Dr. William T. Bull, of New York. The subject of the operation was a colored boy sixteen years of age, and the operation itself differed in certain features from the prior operation of Richardson. The incision was three inches in length from the level of the ninth costal cartilage to two inches above the umbilicus; the upper limit was determined by noting the point where the percussion dulness of the liver disappeared. This incision was chosen because an incision in the median line would be nearer to the œsophageal opening than one parallel with the border of the ribs and the hand or finger operating through it would be less encumbered by the overhanging ribs. This incision exposed a part of the anterior wall of the stomach and its greater curvature about two inches and a half from the pylorus. At the part chosen for the incision into the stomach, two loops of silk were placed two inches apart in a vertical line, and the incision made an inch and a quarter long between them; additional loops in the edges gave greater control over the incision.

The finger, inserted into the stomach through this in-

[1] New York Medical Journal, October 29th.

cision, closed the wound entirely and was passed directly backward until the vertebral column was was felt, and then upward till it entered the œsophagus, thus making the vertebræ a guide to the œsophagus. The anterior wall of the stomach with its loops of silk, followed the finger into the cavity, and was folded on itself like the invaginated scrotum in examination of the inguinal canal. The foreign body was felt and gentle attempts were made to extract it through the stomach. These failing, a slender bougie was passed along the finger, up the œsophagus and projected from the mouth; a sponge was attached by strong silk to the lower end and pulled through with a view to draw the peach-stone up from below. The first attempt was unsuccessful, but a second with a larger sponge brought the stone into the mouth where the finger met and extracted it. A rapid recovery without accident followed the operation.

The noticeable features of the case which contributed to its success are: the small wound in the stomach just sufficient to admit the index finger, the invagination of the anterior wall of the stomach, the control of the stomach wound by loops of thread so that it was held closed against the finger which acted as a plug and prevented the escape of the gastric fluids, and the very moderate manipulation of the stomach itself.

Dr. Bull emphasizes the advisability, when there is doubt as to the possibility of safely extracting a foreign body by œsophagotomy, of resorting promptly to opening the stomach.

THE MISQUOTING OF MEDICAL MEN.

To be misquoted is a misfortune not peculiar to poets. Indeed, in the ordinary affairs of every-day life, it is notorious that men cannot or do not use that accuracy of statement in repeating one another's remarks which public sentiment exacts in the description of other facts. One of childhood's sports is to procure the repetition of a remark through a series of mouths, when it appears, at last, in a form hardly recognizable to its originator.

There is reason to believe that scarcely any other class of men is so universally misquoted as physicians. Two persons discussing any ordinary subject possess, usually, such a common knowledge of that subject, that each can gain the other's thought, not only from what he actually says, but from what he implies. To his neighbor, one's words usually *connote* certain things in addition to what they definitely denote. Any exchange of thought depends upon what is implied, as well as on what is explicitly stated. Hence, there is little excuse if one cannot repeat the substance of views which he has heard stated on any subject in which he and his interlocutor possess an equal knowledge. But, if men fail so often in this, what wonder is it if they cannot correctly report what their physician tells them. When a physician gives an opinion to a patient on his malady, there is rarely between the two that common ground of mutual understanding which makes the latter really understand what the former means. If, then, the patient undertakes to reproduce the conversation, he usually adds to what has actually been said an interpretation based upon his own previously conceived ideas of the subject — ideas which, it is needless to say, are not those of the physician.

Then there is the fallacy resulting from inability to make a verbal repetition. Even a synonymous word may lose the spirit of the original expression. The last words of Webster have been quoted as "I ain't dead yet," by men who thought they were really giving the classic expression of the dying statesman. The "yaller jaunders" is a diagnosis which has been attributed to more than one dignified and scholarly practitioner. Pelvic inflammation suffers comparatively little distortion when it is understood and repeated, as it always is, as "inflammation of the womb," but the often quoted "inflammation of the bowels," may mean peritonitis, typhlitis, enteritis, or colitis, some one of which the physician probably said, and then gave an explanation which was translated by the patient into what he supposed to be a synonymous term.

But, while it is probable that "gastric fever," "lung fever," and "brain fever" really convey as much of an idea to the patient's mind as the more scientific terms of which these are paraphrases, nothing so good can be said of the vagaries as to pathology and ætiology which the layman's previous conceptions have evolved out of the doctor's brief and guarded statement. One is sometimes confounded to hear these views soberly attributed to sensible practitioners, with no suspicion, apparently, on the part of the speaker of their grotesqueness. Indeed, it is not a rare experience for a physician to be quoted to himself as having told his patient on some previous occasion certain things, whose announcement, to his mind, would cast a serious imputation upon the intellectual integrity of any one who might really have entertained them.

The moral is obvious; namely, to accept with reservations any opinion that may be attributed by a patient to a previous attendant; not to consider that a physician, even though it be one for whom one personally entertains no very high regard, is necessarily a fool because a foolish diagnosis or an outlandish statement of any kind is attributed to him. An explanation always possible, often probable, is, as in the venerable conundrum, "the boy lied."

A CASE OF SUDDEN SUPPRESSION OF THE VISUAL MEMORIES.

RIBOT in his "Diseases of Memory," remarks that in physiology the distinction of partial memories is now currently received. "Memory resolves itself into memories, just as the life of an organism resolves it-

self into the life of the organs, tissues, and anatomical elements that compose it."

As memory is only the sum of partial memories, and all our knowledge (based on memory) is primarily derived through the senses, and as all the sense-organs have their centres in the cerebrum where the residua of sensations (to use Maudsley's expression) constitute the memories of each special sense, so certain diseased conditions may obliterate one set of sense-memories by destroying their anatomical substrata, leaving, it may be, intact the memories of other senses.

Charcot, in a recent lecture, has given us a good instance of this suppression of one of the forms of memory. It was a case of loss of the mental vision of objects — forms and colors — coming on suddenly in a subject noted for great intellectual activity, but especially for the strength of his visual memory. This individual would recall the principal features of a landscape, a painting, a play with extraordinary exactness and vividness; his imagination was keen, and he excelled in perspective. He could readily recall what he had read by the mental images of words, lines, sentences, etc., presenting themselves. His memory of persons and places was wonderful. After the accident to which allusion has been made, and what seems to have been of the nature of a limited embolism, he lost his visual memory of forms and colors, and was obliged in the management of his commercial affairs to have recourse to other forms of memory (the auditive, tactual, etc.), which were unimpaired. The city where he lived, his very home, and the faces and forms of the members of his family were at first strange to him; he recognized nobody except by the voice; he could only find his place of business by inquiry. Little by little his visual memories returned, but never completely. He had lost the faculty of drawing; could no longer sketch the form of any object which he had once seen. His memory of colors was gone; he could not form the mental image of black, white, red, etc., and when anything of a bright hue was presented to him, he could not recognize the color. The larger part of what he had learned by reading was forgotten, while the memory of what had been acquired by the auditory sense was as vivid as ever.

This gentleman wrote to Charcot that his "interior vision," once so active and perfect, "had completely disappeared." He could no longer represent to himself the forms and features of his wife and children, or any other person or object with which he had been familiar. His dreams were completely changed; he now no longer dreamed of persons and places, but of voices and words. A remarkable consequence of the loss of this mental faculty was the change of character which he had experienced. He found himself much less prone to sorrow, sympathy and moral emotion than formerly. Having recently lost a valued relative, he felt much less poignant grief than he would have felt could he have represented to himself by the interior vision the physiognomy of this relative, the phases of the disease through which he had passed, and especially, if he could have pictured to himself the external effect produced by this death on the members of his family. He concludes his letter by the remark that he is now obliged to say to himself the things which he wishes to retain in his memory, whereas, before the occurrence of his cerebral lesion, he had only *to photograph them by sight* in order to remember them.

Charcot concludes some very judicious and instructive comments on this interesting case, of whose details we have given but an imperfect idea, by the following observations: "It cannot now be denied that the possible and actual suppression, in numerous instances, of an entire group of memories, of a whole category of commemorative images, without the participation of other groups, of other categories, is a capital fact in pathology as well as in cerebral physiology; it leads necessarily to the admission that these divers groups of memories have their seat in certain determined regions of the encephalon, and adds another proof to those already existing that the hemispheres of the cerebrum consist in a certain number of differential organs, of which each possesses its proper function, while remaining in the most intimate connection with the others. This last proposition is, moreover, to-day generally admitted by those who study the functions of the brain, not only in animals, in the laboratory, but also, and especially, in man, by the procedures of the anatomo-clinical method."

MEDICAL NOTES.

— The Medical Press and Circular says that "most if not all" foreign visitors to the Medical Congress at Washington suffered from more or less severe diarrhœa accompanied by painful abdominal sensations. The affection often failed to yield to remedies, and "some of the unlucky patients were fain to make haste to return to conditions of existence more congenial to their physical happiness." The cause of the malady is ascribed by our contemporary to the peculiarities of the American dietary, including abstention from alcoholic drinks, the use of ice-water and the non-filtration of the water. Query: if the same causes which produced the Englishman's diarrhœa will account for the American's heartburn on that occasion?

— The annual competitive examination for the post of *Internes* in the Paris Hospitals was fixed to take place on October 14th, but had, as we learn from foreign exchanges, to be deferred, on account of the disorder which occurred when the doors of the Examination Hall were opened. The limit of age for the male candidates has always been twenty-eight, but no limit had been fixed for women until alter last year's examination. It would probably not have been done then if great discontent and consequent disorder had not, on that occasion, been caused by the admission to

the examination of Mlle. Klumpke, who was over twenty-eight years of age. In spite of the new rule, establishing equality of age for both male and female candidates, Mlle. Blanche Edwards, who is more than twenty-eight, succeeded in obtaining an exception in her favor. That favor was met with great hostility from the students, who, by their disorderly conduct, prevented the examination from being held. Immediately the doors were opened, they commenced shouting: "*A bas le Ministre! Vive le limite d'age! A bas Blanche!*" etc. As is usually the case with the Parisian mob of the present day, the immediate business in hand was varied with shouts of "*Vive* Boulanger!" There seems to be some ground for the suspicion that female medical students, or, at least, female candidates for the *internat*, are not altogether popular among their male companions.

NEW YORK. — CHOLERA ITEMS, ETC.

— In a letter to Surgeon-General Hamilton, Health Officer Smith denies that the steamer *Independente* passed New York Quarantine without proper disinfection. He states that the vessel was detained more than twenty-four hours, and that all baggage, parcels, and bundles were opened in the steerage and thoroughly disinfected, although the ship's surgeon had disinfected the steerage and passengers' baggage with sulphurous acid gas several times during the voyage. The letter goes on to say: "He had also caused the steerage decks to be washed with a solution of corrosive sublimate (1 to 500). The captain and other officers confirmed the surgeon's report, and the exceptionally good sanitary condition of the ship satisfied me of its truth. . . . There were no deaths during the voyage, and not a single case of illness among the passengers. Since cholera invaded Italy, in 1884, every steamer with passengers from Italian ports, on its arrival at Quarantine, has been detained until every package of baggage could be opened and disinfected."

In a letter in answer to one of inquiry from Mayor Hewitt, Mr. Bayles, President of the Board of Health, says: "It is undoubtedly true that the arrival of ship after ship, crowded with immigrants from cholera-infected ports or districts, is a public misfortune to be averted, if possible. In view of all the facts, I would respectfully urge the desirability of discouraging immigration, and the Board of Health would cordially second any effort you may be pleased to make to that end. If the Federal Government can in any way interpose to check immigration from ports infected with contagious diseases, it should be asked to do so."

— The packet ship *Washington* has been fitted up as an observation hospital by the Quarantine Commissioners, and the passengers of the *Alesia* have been transferred to it from Hoffman's Island. No new cases of cholera have developed among the *Britannia's* passengers, but measles has now broken out among them, and a considerable number of cases have been removed to Swinburne's Island.

OBITUARY. WM. M. CHAMBERLAIN, M.D.

— Dr. Wm. M. Chamberlain died of pulmonary disease October 31st, at Summit, N. J. He was born in 1826, at Hanover, N. H., where his father was a professor in Dartmouth College, and he was graduated both in arts and in medicine at this institution. After serving as an interne at Charity Hospital from 1851 to 1853, he engaged in private practice in New York, and, during the late war, he became a Brigade Surgeon. He served, afterward, on the Sanitary Commission, and, in 1863, resumed his practice in New York. He devoted himself more particularly to diseases of women, and succeeded the late Dr. Peaslee as attending physician in this department at the Demilt Dispensary. He was also identified for many years with Charity Hospital as visiting and consulting physician, and was, at one time, President of the Hospital Medical Board. Dr. Chamberlain was an accomplished member of the profession, and his numerous contributions to periodical medical literature were characterized by elegance of style, as well as originality and practical suggestiveness. For the past three years, his failing health prevented him from attending to his professional work as actively as formerly, and he was obliged to spend much of his time away from the city.

Miscellany.

CREOLINE: A NEW DISINFECTANT.

DR. F. VON ESMARCH, assistant at the Royal Institute for Hygiene in Berlin, publishes an important and interesting article in Vol. 2, Nos. 10 and 11, *Centralblatt für Bacteriologie, etc.*, upon a new disinfectant — *creoline* — which will at once arrest the attention of students, the more especially so, since Prof. Dr. Eugene Fröhner, of the Royal Veterinary High School, has confirmed, by the most careful experiments, the views expressed by Dr. von Esmarch. Dr. Fröhner describes the results as "astonishing," both in regard to internal administration and external application, and believes that its use in mange and itch will be of value in political economic studies. Experiments were made with creoline and carbolic acid with decomposed material, Asiatic cholera, typhoid, and anthrax; the minutest tables of analysis are given in seconds, minutes, hours, and days, all the changes being noted, and, with the sole exception of the bacilli and spores of anthrax, creoline proved itself to be the most powerful germicide. As yet, Dr. von Esmarch is unable to say why it fell behind carbolic acid in anthrax. In the first trial the results were equal, but in the second experiment creoline did not manifest such germicidal power as the carbolic acid. Dr. von Esmarch says: "All of my liquids were thoroughly decomposed, and emitted a most offensive odor. This disappeared almost entirely when a small quantity of creoline was added, and the mixture agitated every few seconds. The same addition of carbolic acid produced no effect, even when a much larger percentage was used." He also adds: "The action of *creoline* preparations surpasses by far those of carbolic make." A comparison between creoline soap and a one per

cent. sublimate soap resulted largely in favor of the former. The attention of surgeons is especially called to its action upon the micro-organisms of wound-infection, and bespeaks for it careful investigation.

ENLARGEMENT AND DISPLACEMENT OF THE LACHRYMAL GLAND INTO THE UPPER EYELID.

At a recent meeting of the Medico-Chirurgical Society of Edinburgh, as reported in the *Edinburgh Medical Journal*, Dr. Argyll Robertson showed a case of this affection. The case was unique in his experience, and also, he believed, in ophthalmic literature. There were cases of enlargement into the orbit which tended to displace the globe. The displacement of the gland in this case was into the upper lid, in which it formed a tumor, occupying its whole length and part of the breadth, preventing its movements. From the history, that it commenced with a degree of uneasiness and increased lachrymation, and from its granular feel, and the circumstance that, though attached above, it was freely movable under the skin, Dr. Robertson came to the conclusion that the tumor was the gland displaced, and undertook its removal. During the operation, he came across the accessory portion of the gland in its normal position, and left it there to provide moisture for the eye, which had quite recovered from the operation. The lid did not move so readily as its fellow, but its movements were much better than before. The patient had deep-sunk eyes and abnormally small orbits, which afforded a probable explanation of the displacement into the lid, instead of into the orbit. The patient was a spirit merchant, and had sustained no injury to the eye, nor had he any inflammatory symptoms. The tumor was observed by the patient in January, when it was about the size of a bean, since which time it had gradually enlarged. The patient also stated that, in the winter of 1885, a small, similar swelling occurred in the lid, which, however, did not inconvenience him much, and disappeared. The removed gland was also shown.

A CASE OF PURULENT PUERPERAL PERITONITIS SUCCESSFULLY TREATED BY PUNCTURE.

The *London Medical Record* (August 15, 1887), quotes from the *Archives of Tocologie*, an interesting case, reported by Besnier, of a woman twenty-six years of age, married two years previously, having had two miscarriages, who was delivered at term Aug. 23, 1886, after a normal pregnancy, the labor lasting fifteen hours. Four days after her confinement, the patient was seized with shivering, vomiting, and abdominal pain. These symptoms persisted, and the vomiting was particularly troublesome, the vomited matter being of a bright green color. Tympanites supervened, soon followed by profuse diarrhœa. On the fifteenth day the patient was taken into the country, where a certain improvement in her condition seemed to take place. The pain, however, remained, though less severe, and the abdomen gradually increased in size. After six weeks in the country the patient was brought back to Paris, where Dr. Besnier saw her for the first time on October 20th. She was then much emaciated, temperature 98°, pulse small and feeble, 100 per minute, profuse perspiration, preceded by slight rigors and general discomfort, bilious vomiting and diarrhœic stools, complete loss of appetite. The abdomen was distended to the extent of an eight months' pregnancy, but offered no zone of resistance on pressure, and tenderness was not marked. The percussion note above was hyper-resonant; below, absolute dulness prevailed, and the shock was distinctly transmitted from one side to the other. Change of position altered slightly the limits of the area of dulness. There had been no hæmorrhage after delivery, and the lochia had run the usual course. It was diagnosed to be a case of purulent peritonitis, and evacuation of the pus was proposed. This was ultimately agreed to, and on Oct. 30th a moderate-sized trocar was introduced into the left side, at the usual site in puncturing for ascites. Five and a half litres of pus came away in the course of half an hour, the belly being gradually compressed. The wound was dressed with iodoform. Immense relief was at once experienced, and no further accumulation took place. Towards the end of November the patient was able to get up, and soon recovered her health and strength. Menstruation returned soon after, without any untoward symptoms.

Correspondence.

PASTEUR ANTICIPATED IN 1812.

Botanic Garden of Harvard University,
Cambridge, Mass., October 31, 1887.

Mr. Editor,— In the course of my reading, I have chanced upon the following passage, which may prove of some interest to your readers. It is taken from "Observations on Hydrophobia," by James Thacher, M.D., Plymouth, Mass., 1812. It seems as if Dr. Thacher's project was in a fair way of being carried into successful execution, after a lapse of more than seventy years.

George Lincoln Goodale, M.D.

From page 300, of the work cited above, the italics standing as in the original:

"Experiments made upon the canine poison in brutes, might be considered as an arduous and hazardous undertaking, but it is not to be deemed altogether impracticable and I will suggest the following project for the purpose. In the first place, dogs when affected with madness, instead of being killed, should be confined and secured that the disease may run its course, and for the ascertainment of many useful facts connected with its several stages. If experiments on dogs should be deemed too hazardous, let other animals of little value be selected, provided a sufficient number can be procured. Having provided for their security in some proper enclosure, let them be inoculated with the saliva of the mad dog, by the point of the lancet, which would undoubtedly prove as effectual as the dog's teeth. The animals thus infected, are to be the subjects of various experiments and the most attentive observation. With some, the inoculated part might be cut out at different stages, to ascertain the latest period in which it may be done successfully. To others, various counter-poisons and specific remedies might be applied to the wound and administered internally. In fact, it would be difficult to determine, *à priori*, the extent of the advantages of this novel plan, if judiciously conducted. You may smile at my project, but however chimerical and visionary it may appear, I would rejoice to be the *Jenner* of the proposed institution; though I might fail in realizing my thousands, I could pride myself in being the candidate for the honor, and the author of an attempt to mitigate the horrors attending one of the greatest of all human calamities."

LETTER FROM BERLIN.

OCTOBER 11, 1887.

The Sixtieth Session of the Association of German Naturalists and Physicians met in its annual session at the beautiful city of Wiesbaden, so noted for its health-giving properties, as well as its encouragement of just such meetings and associations as this one. This Association is one of the most important of its kind in Germany, and draws attendance from all parts where the German tongue is spoken. It numbers many members. The city did its utmost to make the meeting a pleasant one. A large reception platform was erected at the depot and the principal street, Wilhelm Strasse, which leads from the depot to the Kursaal was highly decorated with flags and evergreens. The session was opened at 9.30 A.M., September 19th, by Prof. Dr. Fresenius, of Wiesbaden. The President, in his opening speech said that this was the third time he had the honor to preside over this assembly and it was the third time the Association had the pleasure of meeting in this city. Contrary to human experience the Association is becoming every year more vigorous instead of growing gradually weaker as the threescore years were attained. The growth of the Association during the last two decades was due, in a large part, to the union of the Fatherland, and the increase of freedom, for which we have largely to thank our worthy Emperor, whose interest in the advancement of science is so well known. Three cheers were then proposed for the Emperor, which were given with a will, and a telegram was sent to him. Dr. von Ibell welcomed the guests, as mayor of Wiesbaden, and dwelt on the great good done the city by hygiene.

The scientific papers were then begun, the first being by the renowned chemist, Professor Wislicenus, of Leipsic, and was "Concerning the Development of the Teaching of Isometric Chemical Connections."

Professor Prever, of Jena, read on the subject "Science and Schools." He discussed the question of over-pressure in the schools, and was in favor of the development of the body as well as of the brain. He dwelt at length on the subject of short-sightedness among the scholars, which is no where so prevalent as here in Germany, and which is year after year becoming more prevalent, and which in fact can be noticed to become more and more aggravated as the classes are more advanced. The health of the children also suffers in other respects at school. He thought the short-sightedness was present in such great amounts on account of the poor light in the school-rooms, and on account of the faulty position of the scholars while at study. On account of the unreasonably long duration of the hours of instruction, five hours following after each other, the brain is overstrained, and that additional trouble is caused by the badly-constructed school benches and desks and the holding and carrying of heavy books and other materials. The classics, he thought, occupied too much time in the schools. They were studied by children of too tender years, and studied too much and too long. It were better were the modern languages, modern history and the sciences studied more to the exclusion of the dead languages.

The paper was received with great manifestations of pleasure.

Dr. Schwartz, of Cologne, read a paper on "Hygienic Problems which present themselves to the Physician who Treats Diseases which spread in Epidemics." The author cited the readiness with which the plague among animals was controlled by the authorities by prompt efforts to prevent its spread, and said that efforts in this direction with regard to infectious diseases among men were not nearly so prompt or efficacious, and left much to be desired. Many of the rules which are made for the prevention of the spread of disease among men, conflict more or less with private interests, and are thus rendered more or less ineffective. The public good is too often laid aside for private interests. It is very necessary that early and exact knowledge of a beginning epidemic be had.

Dr. Meinert, of Dresden, read on the "Influence of the Temperature of the Atmosphere on the Mortality of Nursing Children from Diarrhœas." This gentlemen spoke of the insufficient ventilation and too great warmth of the houses during the summer months. It is worthy of observation that the death-rate in the different stories of the house is different. In the rooms of the cellar, which are generally cool, the death-rate from diarrhœal diseases reaches only 4 per cent. It is highest, however, on the ground floor, where it reaches 12.75 per cent. This is supposed to be occasioned by the fact that this floor is exposed both to the direct rays of the sun and to the reflected heat from the ground. In the first, second and third stories the mortality is considerably lessened. Houses which cool off slowly, as brick and stone ones, and the houses of bakers, in which the bake-oven is built, thus keeping up the heat, have more children suffering from these diseases than others. In the working classes the mortality among children from this class of diseases reaches 61 per cent., in the middle classes, 23 per cent., and in the higher classes still less per cent. The better classes, by opening the windows, and clothing their children in a sensible manner avoid this high mortality. It is interesting to notice that in the south of Europe, for instance in Italy, where the houses are built with the idea of being as cool and well ventilated as possible, the death-rate from these diseases is not so high as in Germany, where this ventilation is not thought necessary.

Dr. Ludwig Wolf, of Berlin, read on "The Coast and Inland Climate of Africa." On the coast the rainy and dry periods exist, but in the interior there is no such sharp division. The temperature change in the interior is very great. In Central Africa malaria is the only disease which causes much trouble. Other diseases are present, but not so much as in Europe. He would not recommend emigration in large numbers to that part, as equatorial Africa is not well suited for Europeans. He thinks that males could go there and with care live in good health for a long time, but as to females he did not think they would do so well, as they are more subject to disease in equatorial lands, such as anæmia and its sequences.

Professor Rudolph Virchow read on "Transformismus or Darwinism." His paper was, as is always the case, full of interest and well listened to.

Professor Meinert, of Vienna, read on "The Mechanism of the Physiognomy."

The display of scientific instruments and appliances was a very large one and consisted of those from all parts of the world. The meeting closed its session on the 23d, and was one which will be well remembered by those who attended its sessions.

German gynæcologists have been busy with the statistics of the operation for the complete removal of the uterus for carcinoma. Material is now on hand to determine if the operation is a justifiable one. The testimony is to the effect that it is. It is, without doubt, superior to any other treatment of the cancerous uterus. Up to the close of the year 1886, 811 cases have been collected, with 47 deaths, or 15.1 per cent. With increased experience the mortality is gradually decreasing, and we may expect it to continue to do so. As to immediate mortality the operation shows better results now than the removal of the breast for cancer. The patients are usually prepared for the operation with an antiseptic vaginal injection. One stroke of the knife frequently suffices to open the pouch of Douglas and display to view the posterior fornix, after which the cutting is done cautiously, paring with the finger-nail. Warm water is kept running over the surfaces, and no sponges are used. The peritoneum is opened on the one side and one finger is passed in, which frees the broad ligament from the uterus. The ligament is then in like manner freed on the other side, up to which time the hæmorrhage is very inconsiderable. The bladder is then freed, which is done with the forceps and the knife. The cut borders of the vagina are then united to the peritoneum, just as was done on the other side. It seems to be of little import whether the uterus is removed through an incision made posterior to the neck, or at the side or front of it.

Some turn the uterus over, others draw it down and remove it. Some leave the opening in the floor of the pelvis, others close it. It may be drained either with iodoform gauze or a tube. If easily done the tubes are also removed. It is not the custom here in Germany as in France and England to use the clamping forceps to restrain the hæmorrhage from the ligamenta lata. The prognosis in the total extirpation of the uterus is quite as good as in the supra-vaginal operation, and is rapidly supplanting it.

Those attending laparotomies in the clinics of Olshausen and Martin, are required not to come in contact with any infectious material on the day before the operation, to wear clean linen and clothing, which has not been in the reach of infection, to take a full bath immediately before coming to the operation, to remove the coat, vest, collar, neck-tie, and suspenders before entering the room, not to touch any of the instruments or materials used in the operation. The operator and his assistants wear a suit of muslin, and are thoroughly antiseptic.

Sanger's method of performing Cæsarean section is rapidly gaining confidence among the Germans. Créde, Leopold, and Gusserow have all done the operation and recommend it very highly. Leopold recommends complete closure of the abdimonial cavity with the continued suture after the protrusion of the uterus. The hæmorrhage after the uterine incision he controls by means of a rubber band or manual compression. He is careful to free the uterine cavity from decidua and that the uterine sutures are very exact in their coaptation. The uterus is opened with an incission, beginning near the fundus and extending down to the lower uterine segment, to the place where the peritoneum is movable, and sits loosely on the inferior uterine segment. The cavity is strewn with iodoform and the incision closed with eight silver sutures, which close the muscle without the decidua. About sixteen silk sutures are then applied which penetrate the peritoneum only. The operation is most successful in Germany. The first 50 cases after Sanger resulted in 36 recoveries or 72 per cent. After Porro, 29 died, or 58 per cent. After Sanger, 14 died, or 26 per cent. This shows a difference of 30 per cent. in favor of Sanger.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 29, 1887.

Deaths reported 1,905: under five years of age 639; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 376, consumption 269, acute lung diseases 236, diphtheria and croup, 170, diarrhœal diseases 66, typhoid fever 49, scarlet fever 38, malarial fever 29, cerebro-spinal meningitis 14, measles four, whooping-cough three, puerperal fever two, erysipelas two. From scarlet fever, New York 13, Brooklyn 10, Boston eight, Somerville three, Cambridge, Lawrence, Springfield and Chelsea one each. From malarial fever, Brooklyn 10, New Orleans nine, New York six, Baltimore three, District of Columbia one. From cerebro-spinal meningitis, New York four, Worcester three, Boston two, Baltimore, Nashville, Lowell, Springfield and Brockton one each. From measles, New York two, Baltimore and Chelsea one each. From whooping-cough, New York, Boston, and Nashville one each. From puerperal fever, District of Columbia two.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending October 15th, the death-rate was 17.8. Deaths reported 3,151: infants under one year of age 719; acute diseases of the respiratory organs (London) 280, scarlet fever 124, diarrhœa 68, measles 50, whooping-cough 50, fever 53, diphtheria 29, small-pox (Sheffield) eight.

The death-rates ranged from 14.2 in Leicester to 27.1 in Plymouth; Birmingham 15.1; Bradford 18.8; Leeds 14.7; Liverpool 17.9; London 16.7; Manchester 24.5; Nottingham 17.5; Sheffield 21.1; Sunderland 18.5.

In Edinburgh 16.1; Glasgow 23.4; Dublin 27.3.

The meteorological record for the week ending October 29, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Oct. 29, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 29, 1887, TO NOVEMBER 4, 1887.

ADAIR, G. W., captain and assistant surgeon. The leave of absence for seven days granted on the 27th inst., by the commanding officer, Fort Brady, Mich., is extended twenty-three days. S. O. 251, Division of the Atlantic, October 28, 1887.

BROWN, PAUL R., captain and assistant surgeon. Leave of absence extended one month. S. O. 250, A. G. O., October 27, 1887.

MUNN, CURTIS E., captain and assistant surgeon. Relieved from duty at Fort Canby, Wash. Ter., and ordered for duty as post-surgeon at Fort Klamath, Oregon. S. O. 251, A. G. O., October 28, 1887.

BYRNE, CHAS. B., captain and assistant surgeon. Ordered for temporary duty at Fort McHenry, Md. S. O. 231, Division of the Atlantic, October 28, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 5, 1887.

FITZSIMMONS, P., surgeon. Ordered to the United States Steamship "Marion."

ATLEE, L. W., assistant surgeon. Ordered to the United States Steamship "Marion."

BATES, N. L., medical inspector. Ordered to the United States Steamship "Trenton."

BEYER, HENRY G., passed assistant surgeon. Ordered to the United States Steamship "Trenton."

WHITE, STEPHEN S., assistant surgeon. Ordered to the United States Steamship "Trenton."

RIXEY, P. M., passed assistant surgeon. Detached from the United States Steamship "Trenton" and wait orders.

ASHBRIDGE, RICHARD, passed assistant surgeon. Ordered to the United States Receiving Ship "St. Louis."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING OCTOBER 29, 1887.

BAILHACHE, P. H., surgeon. To proceed to Buffalo, N. Y., Erie, Pa., Ashtabula, Cleveland, Sandusky, and Toledo, Ohio, as inspector, October 14, 1887.

FESSENDEN, C. E. D., surgeon. Detailed as Chairman of Board for the physical examination of cadets, Revenue Marine Service, October 15, 1887. To proceed to Cape Charles Quarantine Station as inspector, October 26, 1887.

SAWTELLE, H. W., surgeon. Detailed as Chairman of Board for the physical examination of officers, Revenue Marine Service, October 27, 1887.

IRWIN, FAIRFAX, passed assistant surgeon. To inspect unserviceable property of Boston, Mass., and Portland, Me., to proceed to Vineyard Haven, and New Bedford, Mass., as inspector, October 8, 1887.

MEAD, F. W., passed assistant surgeon. Detailed as Recorder of Board for the physical examination of cadets, Revenue Marine Service, October 15, 1887.

WHITE, J. H., passed assistant surgeon. Leave of absence extended four days, October 21, 1887.

CARRINGTON, P. M., assistant surgeon. Detailed as Recorder of Board for the physical examination of officers, Revenue Marine Service, October 27, 1887.

FATTIC, J. B., assistant surgeon. Granted leave of absence for seven days, October 28, 1887.

BETTUS, W. J., assistant surgeon. When relieved at Savannah, Ga., to proceed to Galveston, Texas, and assume charge of the Service, October 17, 1887. Granted leave of absence for thirty days, October 21, 1887.

KINYOUN, J. J., assistant surgeon. Granted leave of absence for fifteen days, October 19, 1887.

$250 PRIZE; COMPETITION OPEN TO ALL THE WORLD.

COLLEGE OF PHYSICIANS, NOV. 1, 1887.

The first award under the William F. Jenks Prize-Fund, of The College of Physicians of Philadelphia, will be made by the Committee, for the best essay upon "The Diagnosis and Treatment of Extra-uterine Pregnancy," as soon after January 1, 1889, as may be practicable. Papers for competition must be written in English, and be presented by the said date. The prize essay is to become the property of the College. By order of "The Committee of the William F. Jenks Prize,"

ELWOOD WILSON, *Chairman.*

1517 Walnut St., Philadelphia, Pa., U. S. A.

PRIZES FOR ESSAYS ON MEDICO-LEGAL SUBJECTS.

The Medico-Legal Society of New York announces the following prizes for original essays on any subject within the domain of Medical Jurisprudence or Forensic Medicine: (1) For the best essay — One Hundred Dollars, to be known as the Elliott F. Shepard Prize. (2) For the second best essay — Seventy-five Dollars. (3) For the third best essay — Fifty Dollars. The prizes to be awarded by a commission, to be named by the President of the Society, which will be hereafter announced. Competition will be limited to active, honorary and corresponding members of the Society at the time the award is made. It is intended to make these prizes open to all students of Forensic Medicine throughout the world, as all competitors may apply for membership in the Society, which now has active members in most of the American States, in Canada and in many foreign countries. All persons desiring to compete for these prizes will please forward their name and address to the President and Secretary of the Medico-Legal Society of New York, to whom application should be made for furthers particulars.

CLARK BELL, *President*, 57 Broadway, N. Y.

ALBERT BACH, *Secretary*, 140 Nassau St., N. Y.

DEATH.

Died in Springfield, Mass., November 5, 1887, Pierre Le Breton Stickney, M.D., M.M.S.S., aged seven-three years.

ERRATUM.

In the JOURNAL of November 3, 1887, page 442, second column, third paragraph, ninth line, for "June" read "January."

CLINICAL NOTES ON PEDICULOSIS.[1]

BY F. B. GREENOUGH, M.D.

At one of the recent meetings of this Association, the Chairman of the Committee on Statistics, in calling attention to the various interesting points that were shown in their report, stated that the number of cases of pediculosis reported from Boston was largely in excess of those from the other sections. An examination of the statistics published in the Transactions of this Association for the last nine years shows that this was not only the case during the year referred to, but that the excess has been a constant one.

Having looked up the statistics in regard to a class of cases in which I have always been interested I venture to lay before you a few of the results, although I fear that, to many of you, the subject will appear unimportant and uninteresting.

That practically, however, it is not unimportant, in Boston, at least, is, I think, shown by the fact that, out of 15,551 cases of cutaneous disease recorded on the books of the Department for Skin Diseases at the Boston Dispensary, I find 914, or very nearly 6%, entered as being caused by the presence of one of the three varieties of pediculi.

The following table is condensed from the Transactions of the Association, and gives the numbers of the three varieties of pediculosis reported during the past nine years, as well as the whole number of cases of cutaneous disease.

TABLE No. I.

Statistics of number of cases of PEDICULOSIS reported in the Transactions of the American Dermatological Association from 1878 to 1886 inclusive.

	Boston	New York	Philadelphia	Baltimore	St Louis	Chicago	Canada
Cases of Pediculosis	2132	995	320	113	48	660	39
Cases of skin disease	40970	32578	9269	5295	3312	21229	1173
Per cent. of Pediculosis	5½—	3+	3½+	2 1-6	1½—	3—	3—

A summing up of the nine years shows that the ratio of cases of pediculosis to the whole number of skin affections reported from Boston, is a little less than 5½%; from New York, a little over 3%; from Philadelphia, a little over 3⅓%; from Baltimore, 2⅛%; from St. Louis, less than 1½%; from Chicago, less than 3%; and the same ratio from Canada. That is, that Boston reports nearly double the number that the next largest (Philadelphia) does, and almost four times as many as the lowest (St. Louis). An examination of this table shows several interesting points, but I will only refer to the fact that in 1884, New York, out of 2,737 cases of skin disease reported none of pediculosis capillitii, and also that the number of cases of pediculosis pubis reported from Chicago are very nearly, if not quite, equal to those reported from all other localities.

The relative excess, however, in favor of Boston is even more marked in the cases of pediculosis capitis, as its percentage of these cases is 4%, to New York's 1¼%, Philadelphia's 2%, Baltimore's 1½%, St. Louis's 1%, Chicago's ⅞%, and Canada's +1%; that is, double the next highest, and over four times the lowest. This difference, running with constancy through a period of nine years, shows that it cannot be due to an accidental or temporary cause, and the interesting question to me has been as to what it could be attributed. There is nothing in the geographical situation or climatic condition of Boston that would be especially favorable to the propagation of this class of parasites, nor is there that difference in the mode of life, habits, cleanliness, etc., of the inhabitants, as compared with those of her sister cities, that could explain it. The only explanation that seems at all plausible is, that there is a difference in the observers who record the cases, in their classification of them, and I cannot but think that some cases which, in the Boston Hospital and Dispensary case-books, would be entered as pediculosis capillitii, would elsewhere be recorded as cases of eczema capitis.

I have also tabulated the cases of pediculosis from the records of the Boston Dispensary, with reference to sex and age, as well as relative frequency to whole number of cases of skin disease, and have drawn up four tables; that is, one for cases of pediculosis capillitii, which number 500; one for cases of pediculosis corporis, which number 337; one for cases of pediculosis pubis, which number 27; the fourth one being of cases which, on the record books, are entered simply as pediculosis, without stating of what variety; of these there are 50, which makes the total number 914, occurring in 15,551 cases of skin disease, a ratio of about 6%.

Total Male	..	..	..	..	10	11	1	1	1	2	26

There was only one Female Case which was between fifteen and twenty years of age, and occurred in 1878.

Total, Male and Female, 27.

They each occupy a certain region of the body, and do not encroach on each other's territory, the pediculus capitis confining themselves to the hairy region of the scalp, the pediculus corporis to the body, and the pediculus pubis to the pubic region, axillæ, and that when transplanted from one individual to another, they may get off their own proper ground seems almost inevitable; but, if such is the case, they soon get back there, as they are never, or, at least, rarely seen, except in their own locality. Of the three, the pediculus capitis is the most prevalent. A tabulation of the 914 cases of pediculosis entered on the case-books of my service at the Boston Dispensary shows that 500 were due to pediculosis capitis. I have drawn up the tables with reference to sex and ages, and from them certain facts can be deduced (Table No. II). The proportion of cases with regard to sex is seen to be 81 males to 419 females. In the male cases, of the 81, 34 were boys 5 or under, 25 between 5 and 10, 19 between 10 and 15, and only 3 above the age of 15. In the females, 74 were 5 or under, 172 between 5 and 10, 116 between 10 and 15, and the remaining 57 cases are scattered along, diminishing in number in each five years of age.

Total Female	2	3	4	1	1	5	5	1	2	24

Total, Male and Female, 50.

In both sexes, the great majority of cases occur in childhood, when they are not able to take care of themselves. In boys, the frequency of pediculosis capitis drops off markedly at the age when the hair is cut short, and as they grow older, and become bald, they are, of course, comparatively free from it, my table only showing one between 15 and 20, one between 30 and 40, and one between 40 and 50. That the pediculus capitis produces any lesion of the scalp by its bite is very doubtful; that, when present in any number, they will cause a very decided cutaneous trouble, there can be no doubt of at all. It is, however, such as can in no way, from the character of the

efflorescence, be distinguished from an eczema of the scalp, varying in intensity from a congested, scaly form to an acute pustular one, according to the number of parasites present, or the susceptibility of the patient to irritating influences. When I say that it cannot be distinguished from an eczema due to other causes, I mean only as far as the efflorescence itself goes, as its situation, distribution, etc., are such as to make the diagnosis perfectly easy. There certainly is a great difference in individuals as to their susceptibility to the irritating action of the louse, as we see patients with a violently irritated scalp who do not show as many parasites as we find on others, where the cutaneous reaction is very much less. An invariable accompaniment of the presence of lice is the existence of their ova or nits. These are very characteristic, pear-shaped, semi-transparent bodies, attached to the shaft of a hair. When only a few lice are present, they generally are attached to the hair from one to one-and-one-half or two inches from the root, invariably with the sharp end towards the root; that is to say, the egg is laid by the louse with its head pointed towards the scalp. When the nits are very thick, they will be laid nearer and nearer to the root, sometimes almost touching each other. Sometimes, in the case of women or girls with long hair, they may be found on the shaft farther towards the end of the hair, but, as a rule, they are within two, or, at most, three inches of the scalp end. They are found in greater number on the hairs of the back part of the head, sides, and temples, although, in some cases, almost every hair is covered with them. The parts of the head that are most likely to show this cutaneous irritation are the occiput and crown, especially the former. If the patient has been infested by the parasite for some time, a papular eczema may be found on the back of the neck, and even extending down on to the shoulders. The post-cervical glands also may be found enlarged, especially in the case of children, and frequently, it is this enlargement of the glands that causes the mother to seek medical advice.

The diagnosis of pediculosis capitis, is very easy although it is by no means always an easy matter to see the louse itself. If present, however, in sufficient numbers to cause irritation, the nits can be surely seen. In practice, when I see a case of eczema capitis, chiefly confined to the back part of the head, and also find nits, I consider it, treat it, and cure it as pediculosis. It may be said, that it is possible that a case of eczema of the scalp might happen to get pediculi, without their being in any way the cause of the disease, and theoretically I must admit that it is possible; but practically when such cases treated with a parasiticide, have shown within a week that the eczema was cured or at least very nearly so, as has been the case invariably in my experience, it seems fair to assume that the parasite was the origo malis, and more especially so, when the parasiticide used is of an irritant nature, such as would most decidedly aggravate a simple eczema. The treatment of course is addressed to destroying the cause of the trouble, and for this purpose many things are used. It must be remembered, however, that we must not only destroy the pediculi, but that unless we also either remove the nits, or destroy their vitality, the cure is only a temporary one. I have found nothing so efficacious for routine dispensary practice as an ointment of carbolic acid in the strength of one to sixteen or one to thirty-two, that is, ʒss to ℥i of ung. petrolii. This not only destroys the pediculi but sterilizes the ova, and I have never seen any bad results from it. I must say, however, that in some very bad cases when the whole scalp is a mass of crusts, I have used instead for a few days some tar preparation, diluted with cod-liver oil.

Petroleum is a simple and cheap means of treatment, and is very commonly used. Its inflammability is an objection to its use, however, and I think that that is not the only one. One practical point has been strongly impressed upon me, and that is that if you wish to cure your patients, you had much better not tell them that the trouble is simply due to lice. They will not believe you and will not do what you tell them to, and for this same reason they look upon using such a simple means as petroleum with disfavor. It is a mere waste of breath to argue with them; they will say, and oftentimes truly, that they wash the child's head every day. It has been my experience that it is much better to give them some prescription and strict orders to keep the head clean afterwards. In cases where the mother will do it, the removal of the nits will of course be an additional safeguard, and this can be done very nicely by using a fine tooth-comb dipped in vinegar. A wooden comb is best, and it should be dipped in vinegar between each combing. The vinegar dissolves or at least softens the adhesion of the nit to the hair. By this means with a little patience, the hairs can be combed quite clean. It is advisable of course not to attempt to remove the ova in this way until the acute inflammatory symptoms have subsided.

The pediculus corporis, or as it is more properly called, pediculus vestimentorum, owing to the fact that it abides on the clothes and not on the skin, is in a general way very like the pediculosis capitis. It is larger and somewhat longer in proportion to its breadth, and shows a blackish tinge on the back, to which fact is probably due the name used by sailors to distinguish it from the head louse, that is, grey-back. In my tables it stands second in frequency, the number of cases recorded being 337 to 500 of pediculosis capitis. The relation with regard to frequency between the sexes, is reversed in favor of the males, 196 cases occurring in the male sex to 141 in females. The relative age of the patients is also shown to be the reverse of those in cases of pediculosis capitis, and there is not much difference between the sexes with regard to this point, both of them being more likely to be troubled the older they grow. In males the number of cases increases in each five years, from four cases under five years old, to forty-three over sixty, and in females from eight under five, to thirty-five over sixty. As people get older in the rank of life from which we get these cases, they get careless and perhaps unable to see to their personal cleanliness. While we are not able to see any evidence of the pediculus capitis causing a lesion of the skin by its bite, it seems undoubted that the pediculus corporis does, namely, a congested, infiltrated raised papule. This has been ascribed by some entomologists to the anatomical structure of its mouth, and the literature on this subject is extremely interesting, there being a difference of opinion between some of the best authorities, Burmeister being opposed by Simon and Erichson. Whatever the cause may be, there is no doubt but what these papules cause a most

violent irritation, as patients show the effects of scratching even to the extent of deep excoriations. Whether the body louse, when feeding, goes on to the skin, or feeds without leaving the clothing, I do not know, but in point of fact they are rarely seen on the skin. Kaposi states that when present in large numbers they may be seen on the epidermis after the clothes are removed, but I have never but once seen this, and that was in the case of a very hairy man who was infested with the parasite, when on pulling his undershirt off over his head, I saw one which had evidently been swept off, and was entangled in the heavy growth of hair on his breast. The diagnosis of pediculosis corporis in a severe case is very easy, in a slight one it may be quite puzzling. The fact that not only the parasites but their ova also, are found not on the body, but on the clothes, makes their discovery more difficult than in cases of pediculosis capitis. Even when quite plentiful the pediculi themselves are not easy to see. They hide in the seams of the clothing and it will often take a long and unpleasant handling of the clothes before one can be seen. Generally, however, the nits are more apparent. They are smaller than those of the pediculus capitis, and are attached to the fuzz of woollen clothes, or on the threads of seams. Another evidence is often found in small dark minute spots on the white underclothes, which are the fæces of the louse. The main point to guide us is, however, the distribution of the cutaneous irritation on the body. Owing to the fact that the parasite's home is on the clothing, we find the evidence of its injurious influence on those parts of the body which are brought into the most constant and intimate contact with the clothing. These are more especially, the shoulders, and in persons with a full chest the upper part of the breast, and the waist or girth. The outside of the arms, anterior aspect of the thighs, etc., will be more or less affected in proportion to the severity of the case, but it will be the shoulders and breast, and the small of the back and abdomen where the lesions are found most marked. These lesions may consist of congested papules more or less excoriated, deep furrows caused by digging into the epidermis with the nails, excoriated patches, and even furuncules, but I have never seen the moist or pustular eczematous efflorescence, that we so often see as the result of irritation in scabies, especially on the region of the supinators on the forearm. In cases of long-standing, a very decided amount of pigmentation is found, and when furuncles on the thighs have been started, we may get an inguinal adenitis.

It is, however, the much milder cases which will trouble us in the way of a diagnosis, and in such cases we often have to fall back on the distribution of the efflorescences, or, if the case is so light that no decided lesions are to be seen, on the locality to which the patient refers the pruritus complained of. The fact of old patients being especially subject to pediculosis corporis, makes the differential diagnosis between this and pruritus senilis a difficult one in many cases. The same is true with regard to the pruritus which accompanies hepatic disease and that of other organs. It must also be borne in mind that pediculosis may be coexistent and complicate the manifestations of any other skin disease, and such is frequently the case. Strange to say, however, I have never seen it and scabies on the same patient. In the treatment of this form of pediculosis, we have the opportunity of following the old maxim, "*tollite causam*," and thus accomplishing a cure, by simply removing the infected clothes, or rendering them inoccuous. Unfortunately the class of patients with whom we have to deal is such that this is by no means easy. To disinfect the clothing it is only necessary to expose it to the degree of heat at which albumen coagulates, to kill the lice and also sterilize the ova. Abroad, the hospitals have ovens where this can be done without injury, or at least without serious injury to the garments. In Boston, at the jail and States prison, the clothing is boiled, which effects the purpose, but which in the case of woollen materials is apt to render them a little small in future for the owner. Underclothes can, of course be boiled, and if anybody understands how, and is willing to do it, coats, trowsers and waistcoats may be practically nearly disinfected, by passing a quite hot flat-iron along the seams and creases. In these cases, even more than in those of pediculosis capitis, that I referred to, does one run against a snag by telling the patient that their only trouble is due to a lack of cleanliness and the presence of lice. If you spend ten or fifteen minutes in hauling over their dirty clothes and finally manage to show them a louse, they will say, and many of them really believe it, that the state of their blood is such that they breed vermin. To such patients I simply order a solution of carbolic acid to moisten their skin with morning and night, and urge them to have their underclothing boiled as well as washed. Severe cases, of course, would have to be treated according to the lesions they suffered from.

Pediculosis pubis, in my tables, appears as very much less frequently occurring than the other two forms: I only having twenty-seven cases recorded, and of these twenty-six were males. This can not, however, be taken as a fair ratio of the actual comparative frequency of this disease. Without doubt if I had stripped every patient, I should have found that a very much greater number of them had this parasite. The number entered were those that called for advice for this trouble, and that there was only one woman amongst them is due to the fact that we get very few prostitutes as patients at the Dispensary, and still more that they probably recognize the trouble themselves and use domestic remedies to treat it. The ages given in my table are rather interesting, and what would be expected, that is, that of the twenty-six male cases, ten were between fifteen and twenty, and eleven between twenty and thirty, that is, twenty-one out of twenty-six were between the ages of fifteen and thirty. The only woman was between fifteen and twenty. These statistics would show that the pediculus pubis is most decidedly more frequently found in patients of that time of life, at which they are most likely to have sexual intercourse, and conversely would tend to disprove that the pediculus pubis is often acquired from waterclosets, or other non-sexual ways. One interesting fact with regard to this parasite is ignored in my statistics, and that is its occurrence in young children, on the eyelashes. The reason that such cases, of which I have seen about half a dozen, do not appear in my tables, is that they come under the observation of the occulist, rather than the dermatologist, and it has been due to the kindness of *confrères* in that speciality that I have seen the cases I have. The only way in which I can explain their being in such

a position is by supposing the child had slept with an adult infested with crabs, and had snuggled up with its head under the axilla. Anatomically the pediculus pubis differs much more from the other two, than they do from each other, its breadth being almost equal to its length, and the formation of its anterior pair of claws resembling those of the crustacean form, from which it takes its popular name. The two posterior pair of claws are armed at their ends by a quite sharp, sickle-shaped hook.

In its habits also the pediculus pubis is different, as it is found only on those parts of the body, which are provided with the stout curly body hair, same as that of the beard. When I say that they are only found in these regions, I mean permanently settled there, as it is possible that they may be shaken on to some other parts. Within these regions they may be found anywhere, their most common situation being that from which they are named; but from the pubes, as they multiply, they may wander wherever they can find congenial soil. In hairy individuals the median line of the abdomen seems to furnish a road by which they can reach the sternal hairs and the axillæ. I have also found them on the anterior aspect of the thighs, the lower legs and even on the hairs on the dorsum of the phalanges of the toes as well as the beard, mustache and eyelashes. Their position is a very peculiar one, as they are always found at the root of a hair, and apparently clasping the shaft with their anterior claws. Whether the hooklets are dug into the epidermis when the insect is not disturbed, I do not know, but certainly if any attempt is made to remove it, it will be found to cling in a way that almost causes it to be torn apart before coming off. In fact this does sometimes happen. I am inclined, however, to think that this clinging by the hooklets is only assumed when needed, though I can not be certain. I have for a time tried to get hold of the hair at the root of which the crab was seen, with the hair forceps, and try whether by twitching it out by the root, the parasite would come with it. But it is a very difficult experiment to carry out, as the hairs are so thick and matted together, that is on the pubes, the only place on which I have seen the parasite since I became interested in this point, and, moreover, a negative result would prove nothing, as in trying to separate the hair the crab would be likely to be disturbed and fasten his hooks in the skin. I do think, however, that I twice have had the louse started for one-third to one-half an inch from the skin when the hair was quietly seized and suddenly twitched out.

The eggs are laid on the shaft of the hairs, as with pediculus capitis; they are about the same size, I should say, less translucent, not so pear-shaped, and, in the case where only one is found on the hair-shaft, nearer the root end. This, if the fact, is probably due to the pubic and body hairs standing out with their axes perpendicular, or somewhat so, to the skin, whereas the scalp-hairs, in most cases, at least, are smoothed, brushed, and plastered down, so as to be almost parallel, as to their shafts, with the scalp. It would not seem that the diagnosis of pediculus pubis could be difficult, but sometimes it is, especially in cases where only a few of the parasites are present. In these cases, as in those of pediculus capitis of a similar nature, the presence of the nits is often what we must rely on, unless we wish to pass a long, tiresome, and useless time in hunting at the roots of all hairs. Whether the pediculus pubis makes any idiopathic lesion on the skin, I am not prepared to say. Usually, we find a red, papular, eczematous eruption, chiefly confined to the hairy parts, but sometimes extending beyond. In practice, the cases I see are very apt to be complicated with inflammatory manifestations, due to treatment already undergone.

It must be remembered that patients affected with other skin troubles may become contaminated by pediculus pubis, and, in some very filthy cases, all three of the pediculi can be seen on the same subject.

The treatment, unless the case is complicated, is not difficult, but I should be more cautious in using strong means than on the scalp. For ordinary cases, I find carbolic acid in ung. petrolii answers very well. Where severe, especially if the severity has been caused by irritants, emolients, rest, and tepid bathing; as the case yields, then a mild solution of the bichloride, Peruvian balsam, solution of boracic acid, etc. The amount of damage that is sometimes done by a liberal and repeated use of mercurial ointment, which is the popular remedy, is almost without limit.

The means by which these three parasites are communicated from one individual to another is an interesting question, and one of practical utility. The pediculus capitis are most frequently carried home from school, or the play-ground, or from using the same head-covering, brushes, combs, etc. Not infrequently, we find cases in families that one would suppose would be exempt from such accidents, but when we think of horse-cars, railroad-sleepers, etc., their occurrence does not seem so strange. Servants, also, are the means of contaminating members of their masters' families, especially the children. The habits and modes of life of the lower classes, to whom the pediculus corporis is chiefly, though by no means exclusively confined, are such as to favor the distribution of this parasite. Wearing second-hand clothes, being herded together in tenements, sleeping together, and on foul bedding, are all evident means of contamination. The cases which occur in the better classes may be explained by the use of public conveyances, travelling, and juxtaposition to dirty individuals in crowds.

Up to a few years ago, when the bunks at the Tombs and police stations began to be disinfected, a night's lodging in one of them was pretty sure to be followed by contamination, and such cases were very characteristic. I have seen very few such latterly.

My statistics from the Dispensary show 22 out of 27 cases of pediculosis pubis occurring between 25 and 30. This would rather prove that the contagion was mostly due to actual contact, but the fact in private practice is different, perhaps. I certainly have seen cases where it seemed impossible that the parasite should not have been acquired innocently, and such I believe to be the fact, though, perhaps, in a small number of cases, when we consider the position of this louse, and the tenacity with which he clings, it seems strange that he can migrate from one body to another as often as we know he does. Neither can the nits be easily dislodged from the shaft of the hair, but it may be that this may take place when on the point of hatching, or rather, that the young one comes out of its shell, and is shaken off.

The points that have appeared to me as especially worth noting from the Dispensary statistics are the much greater frequency of pediculi capitis in

children in the female above the male after childhood the decided and marked increase of frequency of pediculus corporis in proportion with advancing years and in the case of pediculus pubis, its existence being almost entirely confined to youth and early adults. These may not be facts of much importance, but, such as they are, they seem to be shown by the recorded cases. After all, some facts of interest can generally be deduced from records of a large number of cases which could be got at in no other way.

A CASE OF SO-CALLED "VICARIOUS MENSTRUATION."[1]

BY F. W. STUART, M.D., OF BOSTON.

THE case which I am to report to-night I saw at the Carney Hospital, from October, 1885, to March 1, 1886, during the terms of service of Drs. E. O. Otis and J. J. Minot, and afterwards at the patient's home, until a few weeks before her death. It was suggested to me that the case was very interesting, and that it might be well for me to report it, since I had followed it longer than any other physician. I am indebted to Dr. Minot for the use of the careful notes he made during the time the patient was under his care.

I first saw the patient in October, 1885. She was then fifteen years old, and the following history was obtained: Her grandfather, father, four paternal uncles and aunts, and two paternal cousins, had died of phthisis, and two more cousins were then "in consumption." The patient had never been strong since three years old, had vomited often, and had frequent "sick headaches." She was always feverish, vomited every night if she ate a hearty supper, and so had been accustomed to limit that meal to a glass of milk. The bowels were always constipated, and she took pulv. glycyrhiz. co. continuously. She frequently had sore eyes. In 1882, she had typhoid fever.

November 24, 1884, the catamenia appeared for the first time, lasted two days, were unattended by pain, but since that time the patient had never menstruated. At the next catamenial period, she vomited everything she ate for two or three days, and the vomiting was repeated at each period, when she also had a feeling of weight and soreness in the lower abdomen. At times, she had a pain in the right ovarian region, when a "bunch" could be felt there, though both pains and "bunch" occurred at non-menstrual periods. She had no trouble with micturition. In May, 1885, she had an epileptic fit. According to the Hospital records, she was treated, in April, for a naso-pharyngeal catarrh, where a note is made, stating that a few days previously she had had an hæmoptysis, though, in October, she did not refer to it. From December, 1884, to June, 1885, she vomited only at catamenial periods, never between. In June, the vomiting began to be much more frequent and severe, everything but milk being vomited. In September, after long vomiting, she raised a little blood, and this was repeated several times. She complained of great pain immediately after eating, and vomited without any signs of nausea appearing.

Such was the history of the case up to October, 1885, though there seemed to be a large element of hysteria in the case, and her truthfulness as regards symptoms appeared rather doubtful. The patient was pale, anæmic, and poorly nourished, but physical examination was absolutely negative, with the exception of localized tenderness in the epigastrium. The diagnosis, it was thought, rested between gastric ulcer and vicarious menstruation. She was put on pancreatinized milk, and all went well until the end of the month, when the usual symptoms appeared, and even this milk was not retained. She now visited a "clairvoyant doctor," and afterwards, a quack in New York City, who told her she had an imperforate hymen, which must be cut. She wished advice as to the cutting, but examination showed a normal hymen, as was to be expected from the history of a previous menstruation.

On December 24th, she visited the Hospital after one of her attacks, and from that time up to March 1st, careful notes of her condition were kept.

On that date, December 24th, she stated that, during the attacks, she had pain in her stomach as soon as food was swallowed, and this pain increased, and was accompanied by a loud, rumbling noise. She never belched wind, or passed any per rectum. After two or three hours of this pain she vomited, but evidently not undigested food. She never vomited directly after taking food, nor in less than two hours after its ingestion. After vomiting, the pain gradually passed away in about one hour.

December 22d. She was sitting quietly, began to choke, and then raised some blood, less than a teacupful, she said. She did not vomit at all, but coughed.

On the night of December 23d and the morning of December 24th, while fasting, she raised dark, thick blood. She had no cough; usually ate no breakfast; has had night-sweats. She sat up late nights, ate very little, danced a good deal, and slept poorly. Examination, superficial, owing to the recent hæmoptysis, showed the patient to be small, poorly developed, pale, and anæmic. No enlarged glands were to be seen or felt. Auscultation gave an almost puerile breathing, and expiration slightly prolonged. There was localized tenderness, limited to a small area over the epigastrium. She was told to take peptonized milk every two hours.

December 25th. She raised blood four times. Each time, she first began to choke, and then raised the blood, which was greater in amount than at any time before. She had considerable cough; complained of pain in the lower abdomen. The peptonized milk was retained. She was given ext. ergotæ fl. Her mother stated that the vomiting occurred at about the 24th of each month, and lasted one week. She did not think the patient vomited in the intervals. The blood seen before the last attack was mostly streaked through the vomitus, but, at the last attack, was as stated by the patient.

December 31st. The patient said she felt better. There had been no vomiting, and no raising of blood since the 25th. Her weight, which had been ninety-two pounds, was now reduced to eighty-seven pounds. Examination gave a percussion-note a little higher in the second interspace on the right than on the left side. There was also a slight difference in the back, between the scapula and the spine, the left being the higher. Auscultation gave nothing abnormal. Heart normal. The lower thorax was long and pointed. There was marked tympanitic resonance on the left side of the upper abdomen. There was nothing to be

[1] Read before the Suffolk District Society, Section of Clinical Medicine, Pathology, and Hygiene, October 12, 1887.

seen or felt. There was tenderness in various spots, in the epigastrium, about the umbilicus, and about the edge of the ribs on the left side. She was given malt and the syrup of the hypophosphites.

January 12th. She stated she had been thirsty of late, and had vomited after drinking much water.

January 15th. She had severe pain for two hours after eating some turkey; had then vomited, but the pain lasted about three hours longer.

January 19th. Seemed better; had not vomited or raised blood in the few days past. She had, from the vagina, a discharge of a yellowish matter, streaked with blood. She complained of pain in both iliac regions.

January 20th. Was unable to urinate, and a sitz bath and spts. ætheris nitrosi were given.

January 22d. Vomited a little after a breakfast of beefsteak, but the vomitus consisted only of bile. Urination was all right.

February 3d. She stated that she had been away on a visit, and, at night, was laughing, when she began to cough, and raised a tablespoonful of dark, clotted blood. She did not vomit. During the night she awoke with a "pain in her belly," and the next morning, after taking some milk, she vomited. The vomiting continued all day, but the next day the patient was better, complaining only of a sharp pain in the lower abdomen. She had more discharge from the vagina than formerly. An examination of the chest showed nothing abnormal. The patient was referred to the gynæcologist, who reported everything normal about the external genitals, and would examine further only under ether. From the history he obtained, he was inclined to think the case one of vicarious menstruation.

February 19th. The patient returned, and stated she had been quite well up to the 11th, when, after going to the city, she vomited sour food, but no blood. On the 12th she was better, but vomited again on the 13th, up to which date she felt well, but then she had pain in both groins, so severe that she was doubled up. Before and during the pain, she had passed bloody urine during several hours, and at frequent intervals afterwards, she passed a urine which was pale, clear, and not bloody, but in small quantities. For a few days, the pain returned in the afternoon, though she passed no blood.

On this date, the 19th, the patient said she felt well, though she was weak, and had no appetite. She said she always had diarrhœa during the attacks of vomiting, but, at other times, she had marked constipation. Walking and riding in the horse-cars, she said, always brought on the pain, though she could ride in a carriage without experiencing any trouble. She was very nervous, easily startled, and said she had "nightmare."

On February 23d, she presented no definite symptoms.

I have alluded to treatment a few times, but have not intended even to outline it. Symptoms were met as they arose, but the main object kept in view was to give a thorough course of tonics, which was done by the exhibition of iron, arsenic, extract of malt, and syrup of the hypophosphites almost constantly.

After March 1st, the patient did not return to the Hospital, and, indeed, discontinued treatment. I was, however, interested in the case, and made weekly calls to keep myself informed as to her condition. This did not seem to change much, though she grew weaker constantly, and cough, night-sweats, and loss of strength became the predominant symptoms. Towards the end of April, I again examined the chest, and found evidences of consolidation at both apices. The patient now developed a fever, which remained for weeks at about 102.5°, diarrhœa of a very severe character set in, and the patient rapidly sank, and died in about two months.

Unfortunately, no autopsy could be obtained.

I feel some diffidence in giving my opinions regarding a case so difficult of diagnosis as this. Still, I will venture to offer a few remarks concerning the diagnosis. In the first place, it is certain that the patient died of a florid form of phthisis.

I do not think that she had a gastric ulcer. To be sure, there was vomiting, sometimes hæmatemesis, and localized tenderness; but, opposed to this, the patient never vomited until two or three hours after the ingestion of food, and the blood vomited only streaked the vomitus. Beyond this, there were days when she retained hearty food, and the gastric symptoms were limited to certain periods.

I believe, then, we are to consider three affections as possible during the earlier part of the trouble; namely, vicarious menstruation, the hysterie gastrique of the French writers, and phthisis.

No one of these meets the case satisfactorily. The manner of vomiting, and the character of the vomitus — partially digested food, streaked with blood — suggest the hysterie gastrique. But later, there was hæmoptysis; that is, the blood was coughed up, not vomited, came probably from the respiratory, not the digestive tract.

Vicarious menstruation may occur from both tracts, but there had been normal menstruation, and the absence of the menses was only to be expected in one so poorly developed and anæmic. Again, the vomiting of blood was only a comparatively late symptom, and, notwithstanding the patient's assertions, no direct connection with menstrual trouble could be definitely established. In December, she coughed up blood, but did not vomit; in January she vomited, but raised no blood in any way, and there was an apparent attempt at menstruation; and, in February, there were no definite symptoms. Both of these affections are extremely rare, and both offer such difficulties in the way of diagnosis, that it is only after a very careful study of the case that one is warranted in making such a diagnosis. Either may have obtained and been followed by phthisis.

It is a question with me whether there was ever any disease beyond phthisis. To be sure, it is hard to reconcile all the symptoms of this patient with this view, especially when such careful observers as the gentlemen mentioned failed to find signs; but it is the one disease which every one connected with the case constantly looked for, and it is the one which caused the patient's death. The uncertainties of the case prevent an absolute diagnosis, and were a constant source of annoyance in treating the case.

— A convention is announced to assemble in Washington on January 19th next, in which representatives from the mercantile interests and from the various sanitary associations of the country will endeavor to induce the next Congress to enact a law against food and drug adulteration.

A CASE OF POISONING FROM ARSENICAL WALL-PAPER.[1]

BY W. EVERETT SMITH, M.D., BOSTON, MASS.

ABOUT the middle of September, 1886, my patient, Mrs. S., changed her residence from the country to the city. She very soon discovered that some ferns in her parlors were withering, but not from neglect or improper care, since although ultimately dying, they revived for a brief season upon being removed to another part of the house. In the early part of November, she suffered from an attack of nausea and a dizziness so intense, especially when she attempted to stoop, that for several days she was obliged to keep the bed. These symptoms persisted in their intensity about a fortnight, and were followed by a sharp attack of facial neuralgia which lasted about a week.

In the latter part of December, the dizziness re-appeared, but in a far milder form than it had been the month before. At about the same time she began to complain of extreme lassitude and a loss of pleasure in pursuits that formerly gave enjoyment. The quiet of her own room was the one thing that she eagerly sought.

Although she suffered from a continual slight nausea, her appetite was unusually good; there was, as she expressed it, an almost constant "gnawing in the stomach." After the eating of food the nausea would increase, and she would complain of a feeling of heaviness and uneasiness throughout the bowels, especially in the umbilical region. Her increase of adipose tissue began to be distressing to her. Although she had always before drank very little water, she now was thirsty all the time. The menstrual functions continued to be regular so that the symptoms presented were considered to be indicative of over-work and loss of nervous energy rather than of any physiological disturbance. The patient herself was disposed to consider her symptoms malarial in their nature, although, contrary to her expectations, quinine gave her no relief. Occasionally, she would speak of her eyes smarting and watering if she tried to use them.

Suddenly, on March 16, 1887, she was taken without any apparent cause with headache, extreme nausea, and uncontrollable vomiting. The usual antiemetic remedies, internal and external, dietary and medicinal, were tried in turn, but all without relief. On the contrary, they seemed rather to increase her distress. The only expedient that gave the slightest semblance of relief was the holding of pieces of ice in the mouth. The vomiting was almost incessant and was increased by assuming the recumbent position. The vomitus consisted at first of mucus, on the third day of free blood, and later of thick yellow bile. Tenderness in the epigastric and right hypochondriac regions speedily developed itself. The temperature and pulse remained nearly normal. The nasal discharge was uniformly bloody. The menstrual functions still remained normal so that the symptoms seemed to indicate clearly an acute exacerbation of the same trouble that had existed all winter in a mild and chronic form.

Although I could not absolutely exclude either a primary gastro-duodenal ulceration or some of the freaks of pregnancy, I remembered the withering of the ferns and began strongly to suspect some form of irritant poisoning to be the cause of sickness. I accordingly sent samples of all the wall-papers in the house (except, of course, plain "cartridge" papers which I knew to be practically free from suspicion), to Dr. Edward S. Wood for examination. Upon analysis, he pronounced only one paper arsenical, but found such an amount of arsenic therein, that he advised its immediate removal.

To settle decisively the question of poisoning, the urine also was examined for arsenic. Six ounces collected on March 23d, the eighth day of the incessant vomiting, yielded numerous crystals of arsenic after re-sublimation in the tube, while a quart of urine collected three days later yielded a very dark deposit upon the tube, but after re-sublimation, scarcely a trace of arsenic crystals. This seemed to indicate not only that there had been a very large amount of arsenic in the system of my patient, but also that a rapid elimination of the poison was taking place.

But the vomiting and prostration continued unabated. For twenty days the patient could retain absolutely nothing upon the stomach. Enemata, both of beef tea and of Murdock's Food were attempted, but could not be retained. Finally, brandy was substituted for them and with better results. The temperature had never risen above 100°, nor the pulse much above 96. At midnight of the twentieth day the nausea and vomiting ceased as suddenly as it had begun. The following morning the patient expressed her first desire for food. We began with Horlick's Food, and although during the next week we changed at her request to Mellen's, Hard's, and to Wells & Richardson's Lactated Food, we returned to Horlick's and found it the best suited to the case. The recovery was rapid and complete in less than a fortnight. There was only one relapse that could be traced directly to arsenic.

It had seemed at first improbable not only to myself, but to Drs. Wood and Whittier, whom I consulted in the case, that the wall-paper already found to contain arsenic could be the sole cause of all this arsenical poisoning. The paper was upon the walls of a small room on the entrance floor of the house where the patient had been very little, the parlors were on the floor above, and her chamber on the floor above the parlors. In hopes, therefore, of finding some other source of arsenic, dress goods and window draperies were analyzed, but with negative results, so far as finding arsenic were concerned. Chromium was, however, found in large amounts in one pattern of dark green dress goods. I had early seen to it that all cretonnes and turkey-red material were removed from the chamber, since they are well-known to be highly charged with arsenic.

The almost conclusive proof, however, that the sole cause of my patient's sickness existed in this room is as follows: The dangerous wall-paper was removed while the patient was convalescent. She insisted that she was not yet strong enough to venture from home and so remained in the house, confined strictly to her room, while the work went on. After the walls had been scraped and washed, and the room thoroughly cleaned preparatory to the laying of the new paper, she ventured to look into the room but remained there scarcely ten minutes. She very soon had a return of nausea and vomiting, which lasted nearly twenty-four hours. I thereupon insisted that she go into the country and that in her absence the entire house be

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene, of the Suffolk District Medical Society, October 19, 1887.

thoroughly cleaned and dusted. This was done, and since her return she has presented no further symptoms of arsenic poisoning.

Another member of the family was affected by the removal of the paper, his symptoms taking the form of a sharp diarrhœa. The other two members did not at any time present marked symptoms of arsenical poisoning, except a noticeably sallow complexion and a pretty constant feeling of lassitude all winter. They had, however, had more exercise in the open air than my patient.

I trust the record of this case may stimulate physicians to investigate more thoroughly than they otherwise might, cases that they hastily assume to be the results of malaria, nervous prostration or other indefinite or undetermined causes. Many of these cases I believe to be simply chronic poisoning from some material source near at hand. The profession has learned that wall-paper and some kitchen utensils are often arsenical, and it is slowly realizing that articles of clothing and of household decoration may likewise be injurious to health, although the subject has not yet received the attention that it deserves. It seems to me that it is our duty as physicians interested in public health and preventive medicine to make renewed and concerted efforts to secure such laws as shall make it a criminal offence for a manufacturer to allow any deadly poison to be in fabrics or materials that are used or that are sold upon the market.

REPORT ON GENITO-URINARY SURGERY.

BY ABNER POST, M.D.

LITHOLAPAXY IN BOYS.

Dr. Keegan,[1] of Indore, Central India, has published a series of papers on the subject of "Litholapaxy in Male Children" during the last four years, and various other papers [2] and reports on the same subject have recently appeared. The writers agree upon the possibility and advisability of Bigelow's operation in very young children. Dr. Keegan would as soon think of performing lateral lithotomy on an old man with a small uncomplicated stone as on a boy whose urethra would admit the passage of suitable lithotrites and evacuating catheters. The reports referred to here represent a total of eighty-nine cases of boys between the ages of fifteen months and eleven years. One case only was fatal and that was a case of Dr. Keegan in which the calculus was formed about a stalk which had penetrated the bladder through the rectum. It was a case better suited to lithotomy, and would have been so treated had the history been more carefully considered on his admission to the hospital.

The calibre of the urethra in boys reaches a much larger size than has been attributed to it.

Dr. Raye operated on a boy of twenty-three months using a No. 9 (English) lithotrite and evacuator. It passed with perfect ease and without any incision of the meatus, which was of comparatively monster calibre. The infant recovered without trouble of any sort. Dr. Raye's last case was a boy of eight and a half. The smallest instrument in his possession was a No. 8. It would not pass the meatus which was incised. The instrument then passed rather tightly as far as the bulb beyond which it could not be passed without more force than seemed advisable. A No. 7 would have passed, but he had no such instrument. In Mr. Willett's case, quoted by Walsham, a lithotrite and catheter of No. 6 (English) calibre were used successfully upon an infant of fifteen months. Dr. Keegan has passed a No. 7 (English) catheter into the bladder of a boy only eleven months old. It may seem strange that a false estimate of the normal size of the urethra in male children should have existed until very recently, but it is really no more strange than that surgeons should have believed up to the discovery of Otis that the male urethra is much smaller than it really is.

Dr. Keegan states that while no hard and fast rule can be laid down, the urethra of a boy from three to six will admit a No. 7 or 8 English; that of a boy from eight to ten a No. 10, 11, and even sometimes No. 14 English, but age cannot always be depended on as the measure of urethral capacity. In some children of four or five it is unsafe to pass a No. 7 lithotrite, although an instrument of this size will sometimes pass readily into the bladder of a boy of only two years of age.

The objections that have been urged against litholapaxy in male children are:

(1) The undeveloped condition of the genito-urinary organs.

(2) The small size of the bladder.

(3) The narrowness of the urethra, and its extreme sensitiveness and liability to laceration.

These objections Mr. Walsham considers chimerical. Thus:

(1) As regards the undeveloped condition of the genito-urinary organs, the small size of the prostate is altogether in favor of the operation, since, as we all know, an enlargement of that organ is one of the chief difficulties attending lithotrity in old men.

(2) The bladder is, no doubt, smaller in young children than in adults. But many lithotritists prefer to work with only two or three ounces of water in the bladder; and, in boys of only three or four years old, the bladder is quite roomy enough to permit of the efficient working of a small lithotrite, and such was found to be the case with the bladder of the infant of fifteen months, operated on by Mr. Willett. Further, a child's bladder is more expansive and commonly in a healthier condition than that of an adult, and, therefore, better able to bear any over-distension than the bladder of old men. But of over-distension there need be no fear if a small-sized aspirator is used, or if care is taken to force in only a limited quantity of fluid if a full-sized aspirator is employed.

Of the third objection, the narrowness of the urethra has been already considered.

Mr. Walsham believes the alleged extreme sensibility of the urethra in children to be over-rated; since, as far as he has observed, boys, when they have once got over the timidity of having an instrument passed, bear it quite as well, if not better, than do lads about puberty and adults. Boys have sometimes felt so little that they have much preferred being sounded without chloroform.

As regards the actual performance of the operation,

Surgeon Major Goldsmith. Indian Medical Gazette, May, 1887.

Raye, D. O'C. Cases of Litholapaxy in Male Children. Indian Medical Gazette, Calcutta, 1887, xxii, May, 129–132.

the same rules hold good as in adults, but certain points are worthy of special notice.

Mr. Walsham thinks, that the lithotrite should be fully fenestrated, and the female blade well bevelled, so that no detritus may be retained between the blades, and the risk of nipping the mucous membrane of the bladder may be avoided.

Dr. Keegan speaks at some length on the choice of instruments. Clogging of the blades of a lithotrite with *débris* is a very dangerous complication in performing litholapaxy in male children, because it has the effect of increasing the size or number of the lithotrite, say from a No. 7 to a No. 8, and in boys there is not much spare room and the effect of increasing the size would be to injure the urethra on withdrawing the instrument.

The evacuating catheter should be furnished with an accurately fitting stylet, in order that any fragment fixed in the eye may be displaced before the catheter is withdrawn.

The meatus should be incised, and no force used in passing either the lithotrite or the evacuating catheter.

The stone should be very thoroughly crushed, as the small size of the evacuating catheter will only allow the removal of small fragments.

Every particle of stone should be removed at one sitting.

The first crushing should be as thorough as possible, so as not to necessitate the frequent passage of the lithotrite and evacuator.

A small aspirator should be employed, to avoid any risk of over-distension or rupture of the bladder.

If the above precautions are taken, Mr. Walsham believes, and the other authors quoted agree with him, that litholapaxy (provided always that, after the incision of the meatus, a No. 5 or 6 lithotrite passes readily into the bladder) will be found as simple and as safe an operation in children as it is in adults; and he thinks that, for all small and moderate-sized stones, it will be the operation of the future in boys and children, as it is in adults; and that the supra-pubic operation will be reserved for the removal of large and hard stones only.

MEDIAN CYSTOTOMY.

Mr. Reginald Harrison[3] writes of the operation as follows: "I think it will be generally admitted that the easiest and simplest method of entering the bladder, say for the purpose of exploring it with the finger, is that known as median perineal urethrotomy, or, incorrectly, as median cystotomy. By this plan, the finger may be readily passed into the bladder," . . . but nothing of any size can be drawn out of such a limited opening. But this opening can be readily adapted to the removal of larger stones, say up to six-ounce urate or oxalate ones.

During the course of a number of operations for the relief of a large prostate, Mr. Harrison found it quite feasible and easy to obtain as free an opening into the bladder by a median incision along the urethra and floor of the prostate as by the ordinary lateral operation for stone. To effect this, the finger having been passed into the bladder by the side of the staff, the opening is extended in the following manner: In the first place, the membranous urethra is slit up along its floor on the staff by a curved, probe-pointed bistoury; in this incision may be included more or less of the perineum, according to circumstances. Any bleeding vessel may be tied before proceeding further. The deep incision is then made by passing the curved, probe-pointed bistoury by the side of the index finger well into the bladder. The staff may be now withdrawn. The blade of the knife is turned downwards towards the rectum, and the floor of the prostate divided from within outwards, commencing at the depression, which exists more or less in all male adults just within the orifice of the urethra. The incision thus made with the knife may be deepened down to the capsule merely by the firm pressure of the index finger downwards. In this way, Mr. Harrison has been able to make as free an opening into the bladder, nearly along the median line of the body, as a lateral lithotomy will permit of.

The advantages of the method described, Mr. Harrison sums up: With such an incision, as much room is gained as by the lateral incision; the liability to hæmorrhage is less, while the facility for getting at any bleeding point is increased. The movements of the knife in one hand are, from the beginning to the end of the operation, under the direction and control of the index finger of the opposite hand. It adapts the median procedure to a wider range of cases than the old median operation. A state of temporary incontinence of urine and thorough drainage is provided for.

Mr. Harrison has no wish to see the median operation supplant the lateral, but desires that it shall be made an "efficient alternative."

PRE-PROSTATIC PUNCTURE OF THE URETHRA.

Under the name of pre-prostatic puncture, Makins refers to the operation usually known by the name of Cock, and tabulates the operations done at St. Thomas's Hospital[4] during the last ten years. The operation has been done during that period forty-six times, for various reasons. In twenty (43.4 per cent. of the whole), it was resorted to for the relief of acute retention of urine, the passage of a catheter having proved impracticable. Of these, four eventually died — two from exhaustion and uræmia, one from pyæmia, and one from an unascertained cause. None of these cases could be said to have died directly from the operation, although it proved incapable of more than temporarily prolonging existence.

In twelve cases (twenty-six per cent.), the indication was less complete chronic obstruction, in which either no instrument, or only a very small one, could be introduced, in the latter cases it being considered that the time gained in ability to commence local treatment of the bladder justified the procedure. Of these cases, also, four eventually died — one of bronchitis and pulmonary congestion, and three of gradual uræmic poisoning.

In the third series of cases, fourteen in number (30.4 per cent.), the operation was performed for retention of urine, complicated by extravasation. Here, as would be expected, the lowest percentage of cures was obtained, as, in five, death resulted, in spite of the operation.

In one instance not included in the above numbers, the operation was successfully performed in a case where a large hæmatoma of the scrotum was complicated by a false passage made by the patient himself in an attempt to pass a catheter.

[3] Lancet, June 18, 1887, p. 1224.

[4] St. Thomas's Hospital Reports, Vol. xv., p. 107.

With regard to the difficulties of the operation, the cardinal one, that of finding the urethra, is shown by the statistics to be unworthy of the importance which has been assigned to it by objectors to the practice. On reference to the table, we find that, in four instances, the operator was unable to convince himself at the time of operation that the urethra was opened, so that the final stage, that of introducing a perineal catheter, could not be proceeded with. In two of these cases, the patient was aspirated over the pubes, and in two the bladder was punctured per rectum, but in three out of the four these measures proved to have been unnecessary, for urine flowed freely by the wound after the operation, showing that the real difficulty had been in passing the perineal catheter, no doubt due, in part, to displacement of the urethra from its normal position, and in part, perhaps, to the smallness of the opening made in consequence.

INFLAMMATION OF THE PRE-VESICAL SPACE, OR SPACE OF RETZIUS.[5]

Dr. O. Pinner (Frankfort on the Main) writes on the above subject. After comparing the anatomical descriptions of the tissue-spaces in front of the bladder given by different authors, Dr. Pinner gives his own methods of studying them. He made an incision in the middle line, above the symphysis, inserted a drainage-tube, and injected soft plaster-of-Paris under considerable pressure. The submuscular space proved difficult of demonstration, owing to the readiness with which the injected matter found its way into the pre-vesical space.

The author is of opinion that these two spaces should be differentiated clinically, as well as anatomically. The muscular space is bounded, anteriorly, by the posterior aspect of the rectus muscles; centrally, by the linea alba; laterally, by the external margin of the sheath of the rectus; below, by the symphasis; and posteriorly, by the transverse fascia of Cooper. The two submuscular spaces are but incompletely separated from each other.

The pre-vesical space is bounded, anteriorly, by the os pubis; above, by the transverse fascia; posteriorly, by the fascia propria and the bladder; below, by the pelvis fascia. This latter space only should be designated as the space of Retzius.

Phlegmons of the pre-vesical space are frequently due to the extension of the inflammatory processes of the bladder, the rectum, the prostate, the iliac fascia, or the pubic bone.

Phlegmons of the pre-vesical space resemble the well-filled bladder. The apex points upwards. Palpitation proves the tumor to originate from the pelvis. The recti can be brought into prominence above the tumor. The tumor can be felt by rectal examination. Bladder symptoms are often present.

If incision is not made, the submuscular abscess generally perforates the skin, or it may perforate into the abdomen. The pre-vesical abscess may perforate through the skin into the abdominal cavity, or into the rectum, the bladder, the vagina, the urethra, or through the incisura ischiadica, into the scrotum, or along the thigh.

This subject was treated in an interesting manner in the JOURNAL of April 1, 1880.

Clinical Memorandum.

WAS IT MUMPS?

BY JAMES B. FIELD, M.D., OF LOWELL.

EDWARD B., seventeen years old, noticed while in good health, a swelling under his lower jaw. When seen by me, both sub-maxillary glands were swollen and extending below them was a moderate amount of puffiness, making the neck look large. At no time was there any parotid enlargement, any rise of temperature, or of pulse-rate. The attack lasted about a week, and did not confine the patient to the house. His chief complaint was that pain on chewing and in swallowing did not permit the gratification of a hearty appetite. There was also some pain from distension of the glands.

In reply to a question of diagnosis raised by the patient, he was informed that he was not suffering from mumps. The reasons for this statement were the absente of constitutional disturbance, and the non-involvement of the parotid gland.

Within two weeks from his recovery his elder sister experienced a similar attack of inflammation of the sub-maxillary glands, but with no parotiditis and with no fever. Another young lady, not a sister, but an intimate friend of the young man, was also similarly afflicted at about the same time, and positive assurance was given me that her parotid glands were not affected.

By this time I was ready to admit the probability that E. B.'s complaint was of a contagious nature, but not that it was mumps. To be sure, it is not uncommon to find the sub-maxillary glands involved together with the parotids in mumps, but on consulting such authorities as were easily accessible, I could find only a single reference [1] to mumps involving solely the sub-maxillary glands, and there the diagnosis rested wholly on the fact that mumps was epidemic in that neighborhood. In the case of my patients there was no epidemic, and as far as known, no sporadic cases of mumps on which to base a diagnosis.

In another fortnight, however, a younger sister of E. B. was taken with genuine mumps; the parotid swelling was extreme, the neck was enormously swollen, and the mouth could not be opened. The diagnosis of E. B.'s case was promptly changed from "don't know" to mumps, and shortly afterward his third and last sister also had unmistakable mumps. There were probably no metastases in any of the cases.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

REGULAR meeting, Wednesday, October 12, 1887.

Meeting called to order at 8 o'clock, by the Chairman, DR. F. I. KNIGHT. The reading of the records of the last meeting was omitted, at the request of the Secretary.

DR. W. EVERETT SMITH read a paper on

A CASE OF POISONING FROM ARSENICAL WALL-PAPER.[1]

A specimen of the paper was shown to the Society, but the amount of arsenic it contained was not known.

DR. B. F. DAVENPORT said: It may be of interest to the Society to know, in connection with this case, that the German government has, during the past summer, passed a new law, to go into effect next spring, in which the presence of two-and-one-half grains of arsenic per square yard is allowed in woven goods, provided it is in an insoluble (?) condition. The presence of arsenic in any arsenical color is forbidden if the poison is present as a constituent part of the color; but if it is present simply as an impure material the law forbidding its presence does not apply. What the grounds for these limits of the new German law are, I do not know, but presumably they are based on some competent experiment.

DR. F. I. KNIGHT asked if that would modify the law in relation to the manufacture of colors also.

DR. DAVENPORT: Yes. The old German law, which is at present upon the statute books, forbids the presence of arsenic in toys and wall-papers, but its enforcement has been suspended, and they allow the presence of arsenic in other things, provided they are to be exported. They are not so particular about other nations as about their own. That reminds one of the oleomargarine law in one of the Western cities. The dairy commissioner, reporting on the subject, said it was immediately gotten rid of by shipping into the neighboring States.

DR. ALBERT N. BLODGETT said: I would like to ask Dr. Smith what degree of reliability is to be placed on the testimony of paper manufacturers or paper dealers, as to the presence or absence of arsenic in their manufactured fabrics. A short time ago in a discussion before this Section the statement was made that the certificates of chemists were often utterly valueless; that paper which was pronounced by competent chemists free from arsenic was found to contain large and dangerous amounts of it. I would like to ask if Dr. Smith has had any experience in the proving of certificates of the chemists of manufacturers in regard to the compounds of arsenic in paper, and what value he places upon them.

DR. SMITH: When I was re-papering my rooms, I was in some doubt as to what dealer to go to, Bumstead, or Gregory & Brown. I went to the latter, and picked out papers that I thought I would like, and saw the analyses. The papers were said to be free from arsenic. I did not engage them to hang the paper, but engaged a wall decorator; he traded for the most part with another firm, the Boston Wall-Paper Company. They had a chemist of whom Dr. Wood and Dr. Harrington had never heard. They had specimens which were said to be free from poison. I finally purchased of Gregory & Brown. Dr. Harrington had marked one specimen "Practically free from arsenic." I went to Dr. Harrington myself, because I wanted to know how much it contained. I should place very little reliance upon the statements of any dealer in wall-paper, because he is in one sense an interested, and in another sense an uninterested party. He may sell arsenical wall-paper in perfectly good faith. He receives it from the producer, and takes the word of the chemist. If it proves to be full of arsenic, of course if there were a law, he would be subject to penalty.

When I was getting the paper, Dr. Wood told me an experience that he passed through. He changed the paper in his house while he was at the sea-shore. Dr. Hills one day asked him what paper he was putting on the dining-room. He replied that it was from a lot which had been examined, as the dealer said, by Dr. Hills himself. Dr. Hills was sure he had not seen it before, and on analyzing it, it was found to be a typical arsenical paper. Mr. Bumstead had the paper taken off at his own expense, and Dr. Wood said the paper-hanger had the most typical case of inflammation about the nails that he ever saw. I think Bumstead, although he has made some mistakes that were reported here last winter, has always acted fairly when he has found any paper that contained arsenic. I am sure that Gregory & Brown are very careful.

DR. DAVENPORT said: It is well to remember that the certificate of the chemist applies only to the particular sample examined. It does not apply to another roll, whether of the same pattern or not. Two rolls of the same pattern may be quite different. One may be free; the other may contain a considerable amount of arsenic.

DR. SMITH: The reason why I spoke as I did about the law, was because Dr. Wood said he had been at the State House, in relation to the matter, but has been rebuffed every time. Testimony is brought forward to controvert his own. If the law were passed, he would be cutting his own fingers, for he gets some income from analyzing the papers. He has been one of the most strenuous in pushing the law at the State House. I would like to ask Dr. Davenport whether arsenic in wall-paper does not exist for the main part as an impurity.

DR. DAVENPORT: I presume it does. Most wall-paper in this vicinity is manufactured by the American Wall-Paper Company. They claim, and with reasonable evidence in favor of it, that they do not now use arsenical colors at all and do not intend to have arsenic in their paper. I have understood that they had last year a thousand samples of paper, just as it came from the factory, analyzed, and found it contained arsenic on the average in some 66 per cent. of samples.

The stock from which the paper is made is largely clay, and this, as well as the ochre, may contain arsenic. All papers with gilt contain arsenic, that is, practically all, because commercial copper is very seldom free from arsenic. Of course the bronze contains copper and zinc. Gilt from the American ore is generally free, but imported ore generally contains arsenic. Then as all chemicals are made more or less directly with the use of sulphuric acid, which is made from pyrites, it may come in that way. And so, well nigh everything, unless it has been specially freed from it, would contain a trace of arsenic.

DR. SMITH said: It seemed to me that the amount of arsenic which would thereby creep into the color would be very small, but I supposed that the arsenic was used as a mordant, and was not washed out.

DR. DAVENPORT: As a mordant, quite a number of large cotton print mills use twenty tons of arsenic a month. A common piece of print cloth may contain three, four or five grains of arsenic per yard.

DR. SMITH had been told last June that Mr. Binney, employed by the Walpole company, made the strong

[1] See page 476 of the Journal.

assertion that arsenic had no business in the chemistry of coloring material at the present time; that it was the lazy greediness of the manufacturers, who allow it to remain in their colors; that they do not take time to wash it out thoroughly.

Dr. Buck said: There is one element of danger in papering rooms which does not often come up here. We may have a paper perfectly free from arsenic and still get arsenic poisoning. A certain number of paper-hangers put arsenic in their paste, and that gradually gets through the paper. I would like to know if any one has seen differences in the number of cases reported in different seasons of the year. In my experience I have seen more cases in the summer than at any other time. I have seen many paper-box workers during the summer, and although I have had the Dispensary work to do at other seasons of the year, I have not seen these patients during the winter or fall months. They have presented themselves chiefly during the early summer. I have thought that possibly it might have something to do with the heat, there being a greater degree of volatility at that season of the year.

Dr. Vickery: Would paper containing two-thirds of a grain to the yard, be poisonous?

Dr. Davenport: Whether it would be poisonous is a question of dispute. Some say yes, and some no. Nobody knows.

Dr. Blodgett: I would like to observe that the chemist of the Roxbury Carpet Works, in which nearly all the various colors are employed, informed me that he never used arsenic, and that it was entirely unnecessary and out of place in the production of any color, and that it was perfectly possible to get all the advantages found in arsenic, from other and safe means. He expressed himself very strongly, and said that the presence of arsenic even as an impurity was unnecessary if proper care was employed in the selection of colors.

Dr. Smith added that a former occupant of the house where this patient lived, had died from some obscure trouble, having had stomach and head symptoms. She supposed it was the drainage, and the plumbers had been over the house again and again, but they pronounced everything in good order. Perhaps the present case may give us some hint as to the cause of that sickness and death.

Dr. Pengra: In what form is the arsenic set free from the wall-papers? Is it in the form of gas or solid?

Dr. Davenport: I believe it is now commonly considered that the danger is from the dust which is removed from the surface and inhaled. It was claimed at one time that there was danger of arseniuretted hydrogen being formed and exhaled as a gas. I believe the latest experiments have shown that this gas is not formed except there is free arsenic present in the color. In the case of Scheele's green or Paris green, each commonly contains a certain per cent. of free arsenic, so that in the presence of moisture and fermentation, arseniuretted hydrogen may be formed. In connection with those hearings which were carried on before the legislature, one of the gentlemen papered a large room with a heavy arsenical paper, and drew the air from the room through a solution which would take out the gas which would be formed. I think it was carried on for some weeks without any result.

Dr. Pengra. I would like to know whether the finish would not have something to do with it.

Dr. Davenport. As I understand it, the danger is of the color being mechanically removed. Of course if the finish is such as to prevent that, the danger is prevented. A rough finish I presume is more likely to be loosely attached than the smooth polished surface. There are a great many interesting questions arising from this. Take a paper which contains a grain of arsenic per square yard. Suppose that it covers a room larger than the average, so that we have sixteen rolls of paper. Such a room would have something like sixty grains of arsenic on the wall. It would take a good many years for the paper to fall off, and if one were in the room and inhaled all of it, it would be a very minute quantity. It seems as if people were more affected by very minute doses than we are accustomed to see when we give it medicinally. One writer says that it has a greater effect, but I do not know why.

Dr. Pengra said, I would agree with Dr. Davenport's statements that the arsenic would not become arseniuretted hydrogen, but the process of fermentation may produce that gas. During the past four years I have seen students to the number of from one hundred to two hundred, working in a laboratory where the gas was generated every day, each student probably generating from six to ten volumes in a moderate-sized room. They did this during six to nine months of the year. I have never seen a student suffering from anything like arsenic poisoning. I have seen students suffering from the fumes of amyl alcohol, and from sulphuretted hydrogen; but never has there been a case of arsenic poisoning among students who have been there two years.

Dr. F. W. Stuart then read a paper on

A CASE OF SO-CALLED "VICARIOUS MENSTRUATION."[1]

Dr. Blodgett said: I would like to ask if any medical person witnessed the expectoration of blood at any time.

Dr. Stuart: No; it was something that we attempted to do; I gave notice to the mother to call me at any time that the patient raised blood. My office was only a block from where she lived, but they never sent for me. The mother was hysterical, as well as the girl, and we thought she lied a little more than her daughter did. That was one of the elements that was pretty hard to determine. It was hard to say whether she vomited the blood or raised it by coughing. She insisted that the vomitus was streaked with blood after severe vomiting. That we could see ourselves. She afterward said she coughed up thick blood; that we never saw.

Dr. J. L. Foley asked whether the blood were dark or scarlet.

Dr. Stuart replied that the patient said it was dark. If it were from the air passages of course we would expect it to be bright.

Dr. Blodgett said: I have had the opportunity of examining three cases where the presence of blood was important. One of these was a case where the blood was expectorated by the patient, to the great alarm of the family and the consternation of the physician, who could find no legitimate cause for it. It was finally made evident that the patient willfully and

[1] See page 474 of the Journal.

voluntarily produced the blood from somewhere within the oral cavity. It was satisfactorily determined that the blood did not come from the stomach or lungs, but from some mucous tract above the œsophagus or trachea. A second case which came under my observation was one in which it was believed by the medical man and by the patient that an actual hæmoptysis had occurred, in which the blood followed coughing, and was produced in a fresh or comparatively fresh condition, although never frothy. That was finally, by close study, found to be due to an oozing from the nasal or pharyngeal mucous membrane, which trickled down into the larynx, and then was coughed from the upper portion of the respiratory tract. No symptoms have followed the accident, and they have for many months been carefully watched for. Once or twice it has been noticed in other members of the same family, but it seems to be due to a peculiarity of the patient, and not to organic disease.

The third case was one in which, absolutely, blood was lost in large quantities. Sometimes in quantities estimated at from a teacupful to half a pint. I have never seen the hæmoptysis going on, but I have seen the blood which was produced after the expectoration had ceased. This blood was supposed to come from the lungs. In consultation, a physician of great experience and eminence, pronounced it blood of pulmonary origin. On one occasion I was fortunate enough to see the blood which was formed in distinct coagula. The nurse, who was competent, said that it was found in the mouth in that form, so that the finger had to be used to break up the clumps. This showed that it did not come from the lungs, but from some other part of the body; and I came to the conclusion that it all came from the stomach. The autopsy showed that it came from the exudation of blood through the wall of the stomach without ulceration. There was no other source from which it could have been derived. The lungs were diseased, but there were no cavities, and no signs of a pulmonary origin of the hæmorrhages. There was no crackle, which usually follows the effusion of blood into the pulmonary tract. These three cases have been of interest as presenting three conditions, in each of which the expectoration of the blood was the principal symptom, each of which seemed to analyze itself into a different form from the others, and that is the reason why I asked the question whether any medical person had seen the expectoration going on in this particular patient.

DR. VICKERY. I would like to ask Dr. Stuart how regular, according to her own statement, the loss of blood was. Was it at just the right time?

DR. STUART. Everything depends on how a man reckons the right time. She said that she began about the eighteenth to feel badly, on the twenty-third she began to vomit, the vomiting lasted just one week, and then it all ceased until the next eighteenth. This was the same whether the month had twenty-eight or thirty-one days.

DR. VICKERY. How many months were there?

DR. STUART. From October to January. At each period the symptoms differed. She came to the hospital in October, and said that she had had the vomiting in September. We took her word for that, and then the question was whether she had gastric ulcer. She was told to go home and eat a good hearty meal. She came back and said: "Doctor, the moment I took it, I vomited." We put her upon pancreatized milk. Her vomiting began in June, but she raised no blood then. In December she "coughed" up the blood, but did not vomit any. In June she had made an apparent attempt at menstruation. At one time previously she had had a discharge of blood from the anus.

DR. VICKERY. The hæmorrhage was seen?

DR. STUART. Yes; she did have hæmorrhages. Each time there was blood somewhere.

DR. BUCK. Did she have a small thorax from tight lacing?

DR. STUART. No; she never wore corsets.

DR. VICKERY. I don't think the slightest belief should be given to hysterical patients. One once brought me some live earth-worms which she declared she had vomited. That well illustrates the unreliability of this class of patients.

DR. STUART. The chief interest seems to centre upon this: the girl was an only daughter. The mother was a widow, and thought everything of the girl. The father died of phthisis. There was phthisis everywhere in the family. We asked the question, Is this phthisis? We found no signs in the lungs. The question of vicarious menstruation was raised. It seems to me that the whole thing from beginning to end may be phthisis.

A physician in Boston told me that he was called to see such a case out of town. He found the patient with marked signs of phthisis; cavities in both lungs. The attending physician, who was a man with a large practice, said that it was vicarious menstruation, and that when puberty was established the child would get well. In this case I can only suppose that she had phthisis, and we did not get the signs. Dr. Bowditch examined her once. She was examined by several other gentleman, all of whom pronounced her entirely free from signs. Still, I believe that phthisis was there. I think the whole thing was phthisis.

DR. FOLEY. Did she have any of the symptoms of phthisis, as distinct from the physical signs?

DR. STUART. She was feverish all the time, she said. She also had night-sweats. She said she did not have much cough, but I do not think any reliance was to be placed on that.

DR. KNIGHT. How long from the first blood to the appearance of physical signs?

DR. STUART. Seven months, from October to April.

DR. KNIGHT. It seems to me it must have been the experience of all physicians who have seen such cases that patients not infrequently have hæmoptysis come on sometimes for months or years before the appearance of physical signs. I have frequently met such cases. It is quite the rule, I should say, for patients to have hæmoptysis, and then phthisis after six months. It seems to me that it is not inconsistent with the development of tuberculosis. Supposing when you first examined the case you had found physical signs in the lungs. The question of menstruation would not have entered your head.

DR. STUART. Certainly not.

DR. KNIGHT. Why the difference?

DR. STUART. She was so positive that it occurred so regularly. They questioned her vomiting blood as she said, but certainly I saw vomitus that was streaked with blood.

DR. KNIGHT. Do you think that gynæcologists would accept the fixed date?

Dr. Stuart. No; I do not think so. My view of the case was that it was phthisis. That the vomiting that we had here was hysterical. That the periods came so was due to the hysterical condition of the patient. I don't see why a phthisical patient might not vomit every three or four weeks. It is very easy for a man to be misled, I think. In this case vomiting occurred every three or four weeks in the course of the phthisis. In regard to the question of hysteria, it was admitted by the other physicians who saw her, that her statements were all open to doubt. It does not stand on my own authority.

Dr. Blodgett then showed the following

NEW INSTRUMENTS:

A stethoscope, with a membrane arranged in the bell extremity in such a manner as to intensify the sounds. Of its efficacy he could not speak, as he had not tried it. It also had the merit, the advantage of which was first pointed out by Dr. Haven, of having the flexible tubes so long that the examiner may keep at a greater distance from the patient. The value of this is seen especially in the case of children, and patients infested with vermin, or in persons in whom the breath is unusually offensive.

The so-called "avitreous" thermometer was also shown. Its chief advantage is in the fact that it will not be readily broken. Some of the members would critcise it on the ground of cleanliness, since it has lines of union which would be difficult to keep free from impurity.

A new double catheter was also shown. The return current is by a series of channels formed by the urethral wall on the outside, and grooves in the metal on the inside. It may answer a useful purpose when it is desired to wash the surface of the urethral membrane.

A new series of antiseptic instruments has an adjustable handle, which allows the metal portions to be readily removed, and thus be subjected to cleansing processes that the ordinary handles would not permit. The instruments were kindly loaned by Messrs. Leach & Greene.

Specimens of the leaves from which the new local anæsthetic,

GLEDITSCHINE,[3]

is derived, and some of the two per cent. solution of the active principle itself were also exhibited. A short description of the circumstances of its discovery [4] and its properties was given.[5]

THE NEW YORK ACADEMY OF MEDICINE.

Stated meeting, November 3, 1887.

Dr. Joseph D. Bryant, Commissioner of the Board of Health, read a paper entitled,

HOW CAN THE PROFESSION AID THE BOARD OF HEALTH?

While there ought undoubtedly, he said, to be the most complete harmony between the two in all matters pertaining to the public health, in the past this had by no means always been the case, and they had, as a rule, been much greater strangers to each other than they ought to have been. He believed, however, that they should both labor with common purposes, the prolongation of human life and the alleviation of suffering. It was the province of the Board of Health to deal more particularly with the prevention of disease, and of the medical profession with its treatment; but the preventive measures of the Board ought, of course, to meet with the active and cordial support of the profession.

Dr. Bryant first gave a sketch of the organization of the Board under the recent head of the Department, General Shaler, in which there were seven divisions, all subject to a semi-military system. From a practical point of view, however, this system was found to be more ornamental than useful, and circumlocutory rather than thoroughly efficient. He then spoke of the present organization of the Board, and described the more important changes which had been introduced under the administration of President Bayles.

Among these was the relieving of the medical officers of the Board from the duty of making general inspections; one which was now performed by a corps of lay and police sanitary inspectors. There were forty-five members of the sanitary police corps, each having charge of the inspections in one of the forty-five districts into which the city was divided, and it was their special duty to systematically and thoroughly inspect all the tenement-houses in their respective districts. The lay sanitary inspectors were fifteen in number, one to each of the fifteen larger districts into which the city was divided. It was their duty to make inspections of buildings other than tenement-houses, to investigate complaints made by citizens, and to deal with problems too deep for the sanitary police, by whom such problems were referred to them. All the medical sanitary inspectors are now detailed to the department of contagious diseases, and it was their duty to at once visit the locality of any case of contagious disease reported to the Board, and see that proper measures for isolation, disinfection, etc., were promptly and thoroughly carried out. When, in any instance, it was found that suitable medical treatment could not be pursued, or that isolation of the patient could not be secured, they would advise that the case be removed to the hospital. They were especially charged that they were to coöperate in every way with the medical attendant in charge of the case, and always treat the latter in accordance with the strictest rules of professional etiquette.

The medical officers were thus restricted to work entirely professional, and the most ample opportunities were afforded by the present system for the scientific investigation of disease. In order to further this object, promotion and the increase of salary were made dependent on faithful and intelligent service. In the department of contagious diseases was included the bureau of vaccination and contagious disease in animals, and employed in the latter were expert diagnosticians in this special field. In addition the services of Drs. T. Mitchell Prudden, of the College of Physicians and Surgeons, and Hermann M. Biggs, of Bellevue Hospital Medical College, had been secured as Pathologists by the Board. The utility of this measure had already been demonstrated in the determination of the true character of a suspected case of Asi-

[3] The Alkaloidal Active Principle of the Gleditschia Triacanthos, or Thorny Locust. (Journal of Am. Med. Association, October 15, 1887, p. 500.)

atic cholera at quarantine, by the cultures of bacilli found in the discharges of the patient.

Convenient and comfortable means were provided for the transfer of patients to the hospitals of the Board, and the admirably constructed Willard Parker Hospital, at the foot of East 16th Street, was fitted up with all the modern appliances for the successful treatment of disease. It had accommodations for seventy-five or one hundred cases of diphtheria and scarlet fever, an efficient house-physician, and a medical board consisting of such men as Drs. E. G. Janeway, Joseph O'Dwyer, Stephen Smith, George F. Shrady, D. M. Stimson and A. Jacobi. The Reception Hospital was also under the supervision of the same medical board. On North Brother's Island were the fine new small-pox hospital and five pavillions, each with accommodations for twenty-five or thirty patients, for contagious diseases other than small-pox. On this island there was also considerable unoccupied space on which temporary structures could be erected in case of emergency. Every provision was thus made for the comfort and welfare of patients suffering from the various forms of contagious disease.

The Board was at this time paying special attention to the matter of contagious disease, and the urgent need of this was sufficiently attested by the fact that from the 1st of January to the 30th of September of the present year there were no less than 1575 deaths from diphtheria reported in the city. There was entirely too much indifference on the part of the public to such affections as diphtheria; while a single case of a disease like cholera, the prevalence of which would seriously interfere with the business interests of the community, would at once cause profound excitement and receive the greatest possible attention. The Board had great odds to contend against, as it was estimated that from fifteen to twenty-five per cent. of the cases of contagious diseases occurring in the city were never reported by the medical attendants in charge of them. It was estimated also that from twenty-five to thirty per cent. of the births were unreported.

Dr. Bryant concluded this portion of his paper by referring to the provisions of the Board of Health for carrying out the work of the Bureau of Vital Statistics, for the examination of food, the enforcement of the laws regulating the construction of tenement-houses, etc. He then proceeded to answer the question, How can the Profession aid the Board of Health? This could be done, he thought, in the following ways:

(1) By reporting at once all varieties of nuisances dangerous to life or health.

(2) By promptly reporting all cases of contagious disease. In this way many valuable lives could be saved and epidemics could be averted.

(3) By enforcing strict isolation and employing suitable disinfectants and antiseptic measures in cases of contagious disease.

(4) By reporting all cases in which isolation cannot be secured or proper medical treatment be carried out.

(5) By visiting the Willard Parker Hospital and thus being able to speak from personal observation of the advantages which it affords.

(6) By being careful not to send patients with contagious diseases to the dispensaries.

(7) By heartily coöperating with the medical inspectors of the Board of Health in any case in which the latter are met with.

(8) By reporting all food or drink adulterations coming under notice.

(9) By reporting any instance observed of decaying fruit or other kind of unwholesome food offered for sale.

(10) By reporting all defects in plumbing, light and ventilation observed in houses visited.

(11) By paying special attention to the sanitary condition of the homes of patients.

(12) By promptly reporting all births. This was of special service in securing the more general vaccination of infants.

(13) By the appointment of a committee of physicians, not less than five in number, to confer with the Board of Health, whenever such conference seems desirable, on all matters pertaining to the public health.

DISCUSSION.

DR. E. G. JANEWAY said that the suggestions made by Dr. Bryant covered most of the matters in which the profession could be of service to the Board of Health. The importance of reporting all cases of contagious diseases could not be over-estimated, and the statistics of disease could never be made accurate until every physician was willing to report every case he met with. He had known the recurrence of small-pox in New York to be due more than once to unreported cases of the affection. The benefit of reporting all cases of typhoid fever, for instance, had been repeatedly shown in England, in enabling the authorities to trace the origin of the trouble to contaminated milk. The relation of contagious diseases to the public schools was a matter of vital importance, and it was absolutely essential that the school officers should be promptly informed of the existence of a contagious disease in any family, a member of which was one of the scholars. It was also highly desirable that physicians should report every case of *suspected* contagious disease coming under their observation. Public opinion in sanitary matters was moulded by the medical profession, and it should be the aim of the latter to inspire the public with confidence in the Board of Health. Otherwise, the influence and efficiency of the Board would be seriously impaired.

The good work done by the Bureau of Vaccination had undoubtedly been the means of successfully controlling small-pox in the city during the last few years, and it was essential that this should be continued in the future, and that even more vaccinations should be made than in the past. When, as was occasionally the case, unfavorable circumstances attended vaccination, it was not uncommon to hear physicians intimate (and usually without adequate reason), either that the virus used was bad, or that it was contaminated with syphilis. Such slighting remarks did a great deal of harm, and he had known them to be the means of preventing a large number of vaccinations, as reports of this kind were apt to spread through tenement-houses.

DR. A. N. BELL, editor of the *Sanitarian*, spoke of the occurrence of sore throat and other troubles in a family as the preliminary symptoms of bad plumbing, which, if the defects were not remedied, would sooner or later eventuate in diphtheria, enteric fever, or membranous croup. He believed that nine-tenths of the houses in New York were still badly plumbed, as they were built before the present laws in regard to plumbing were enacted. The importance of securing the attention of the Board of Health in such cases

was, therefore, self-evident. He also spoke of the preliminary symptoms of defective ventilation, which would finally terminate in pneumonia if the trouble was not corrected, and said that the great mass of cases of pneumonia occurred in children and old people, who were largely confined to the house. It was also a fact that eighty-four per cent. of the cases of phthisis occurred in those living indoors.

Dr. Andrew H. Smith said that it seemed to him that a new era in the sanitary history of New York had been marked by the appearance of an official representative of the Board of Health, like Dr. Bryant, before the medical profession of the city, to ask for their coöperation in its work. In the past, there had not been those cordial relations between the two which should have been the case, and the Board of Health had been regarded very much as an athlete who struck out from both shoulders, aiming its blows, on the one side, at the public, and, on the other, at the medical profession. He had always believed that the Board should be the outcome of the profession, and be in full sympathy with it; and he could not but feel that Dr. Bryant's paper would be of great service in promoting the sentiment of a community of interests. When medical men could be convinced that the Board was a part of the profession, its usefulness would be greatly increased, and he had little doubt that, from this time forth, such would actually be the case.

Dr. C. R. Agnew expressed much the same sentiments as Dr. Smith.

Mr. Bayles, President of the Board of Health, who was present by special invitation, said that he had been gratified to note the gradual increase of interest in the work of the Board on the part of the medical profession during the past seven or eight months. At first, he had encountered much hostile criticism from physicians; but now there was a much better understanding, and this, he believed, was to a large extent due to the influence of Dr. Bryant, who, since his appointment as Health Commissioner, had been unintermitting in his endeavors to increase the efficiency of the Department. As to the plumbers of the city, at the time when he assumed the Presidency, they were unanimously and most cordially opposed to the Board, which they regarded as an unintelligent, hostile power. He visited the Master Plumbers' Association, and invited its members to join him in a revision of the plumbing ordinances, and the result was that now, instead of being out of sympathy with the Board, and opposing obstacles to its work, they acted in hearty coöperation with it. In the same way, he had endeavored to conciliate other lay interests, leaving to Dr. Bryant the business of dealing more particularly with the medical profession. Mr. Bayles asked for the moral support of the profession when the Board was unjustly assailed by the newspapers, as was sometimes the case, and spoke of the advantage it would be to the Board, when it presented its budget of expenses to the Board of Estimate and Apportionment, to have a committee of physicians of high standing in the community to testify to the importance of its needs. In conclusion, he said that, with the coöperation of the medical profession, there was nothing which the Board of Health could not accomplish, while, without such coöperation, it was powerless.

The President, Dr. A. Jacobi, said that, from his personal knowledge, he could state that there were very few private houses in the city where scarlet fever and diphtheria could be treated under such favorable circumstances as at the Willard Parker Hospital. It was to be regretted that its advantages were not more fully appreciated by the profession and the public, but he did not doubt that the time would come when several such hospitals would be required in the city. When a case of scarlet fever or diphtheria occurred in one of the crowded tenement-houses, it was a pretty safe prediction to make, that, within a month, from five to ten per cent. of the children living in the house would be dead. If all the well children could be at once removed to other localities, it would be the best thing to be done; but, as this was manifestly impossible, the next best thing was to remove the sick at the earliest possible moment, and he said he could not let this opportunity pass without endeavoring to impress upon the gentlemen present, especially those engaged in dispensary practice, the great importance of sending children from the tenement-houses to the hospital.

On motion of Dr. Ellsworth Eliot, the President was authorized to appoint a Committee of five Fellows of the Academy (of which he himself should be one) to confer with the Board of Health in the manner suggested by Dr. Bryant in his paper.

The President introduced Dr. H. W. Boone, Professor of Surgery in St. John's Medical College, Shanghai, who spoke of

MEDICAL WORK IN CHINA,

and made an appeal for contributions of books to the medical library, and of specimens to the museum at Shanghai, which it was designed to make the medical centre, as it was already the commercial metropolis of the country. Such contributions may be sent to the care of the Rev. Wm. S. Laryford, 22 Bible House, New York.

Recent Literature.

A System of Obstetric Medicine and Surgery, Theoretical and Clinical. By Robert Barnes, M.D., and Fancourt Barnes, M.D. 8vo. pp. 884. Philadelphia: Lea Brothers & Co., 1885.

The advent of this treatise has been eagerly awaited by obstetricians, and a work of surpassing excellence expected from the distinguished senior author: we regret to be obliged to express our disappointment. Apart from numerous errors, the diffuse and pedantic style of the book renders it unsuitable for students; and an underlying vein of egotism and conceit will make its use distasteful to many practitioners.

While the space at our command will not warrant a critical examination of the work, we would express our especial disappointment in the chapter on the Puerperal Fevers. Only two pages are accorded to the consideration of the agency of microscopic organisms in causing puerperal infection, and the teachings on prophylaxis are painfully inadequate and absolescent.

That the book is without value to specialists competent to use it, we by no means intend to imply. Teachers will often doubtless turn to its pages in making comparative references; and careful perusal will reveal many pearls of wisdom from the rich experience of Robert Barnes.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 17, 1887.

THE FIFTEENTH ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

THE meeting of the American Public Health Association, in session from the 8th to the 11th of this month, at Memphis, Tenn., appears to have brought together a very large representation of the sanitary authorities of the country, as well as members of the medical profession and others interested in public health questions.

The place itself furnished a striking object-lesson; brought to the doors of destruction by the fearful epidemics of yellow fever in 1878–79, it flourishes now in greater prosperity than ever. The death-rate has been much reduced, and the excellent system of small sewers, constructed by Col. Waring, drains effectively all of the city now connected with it. A good water-supply is still wanting, but several plans are now under consideration, from which the needed relief is expected.

The people of Memphis believe that they owe much of their sanitary improvement to the Association and the National Board of Health. They were, therefore, glad to welcome their guests, and did make the meeting a most enjoyable affair.

Dr. Sternberg, the President of the Association, has quite recently returned from his scientific mission to Mexico and Brazil; whither he had been sent by the President of the United States, for the purpose of studying the inoculations of Carmona and Freire, for which so much has been claimed. It was naturally to be expected that some of the results of his observations would be presented at this meeting; the somewhat peculiar instructions, under which Dr. Sternberg acted, forbade, however, any publication whatever, of his conclusions until the final report should have been made to the President.

Dr. Sternberg's address is of very great interest, and deserves a careful reading by all who are interested in the scientific side of the questions relating to the prevention of disease. He is one of the very few, who have, on this side of the Atlantic, made original investigations in the study of the harmful microörganisms; and has, under the painful limitations to which national sanitary investigations in this country are subjected, made contributions of generally recognized value to our knowledge in this direction. A concise statement of the present condition of bacteriology, founded largely on personal experiments, was the main feature of the address.

The question of a permanent National Health Authority, was given a prominent place in the proceedings of the Association. We notice with satisfaction, that the President recommends the establishment of a Bureau of Public Health in the Department of the Interior, a plan advocated by this journal since it became evident that a National Board of Health could not be reconstituted. The Association adopted the recommendation and appointed a committee to bring the matter to the attention of the next Congress.

A defence of the New York Quarantine Station against the many criticisms that have been made upon its quite inadequate equipment and defective administration, was attempted by Dr. A. N. Bell, of New York. Though his statements appear to have been made by authority, they produced a most convincing impression of the shameful condition of the quarantine service at our principal port of entry.

The contrast between New York and New Orleans was very distinctly marked, when Dr. Holt, of the State Board of Health, of Louisiana, read his account of the quarantine station below New Orleans and its operation.

New York allows Dr. Smith, the Health Officer of the port to receive, in one way or another, the enormous compensation of more than fifty thousand dollars, as generally reported, and spends almost literally nothing in extension or maintenance of the station. New Orleans, notwithstanding that she has replaced, by Dr. Holt's energetic administration, the fears of the whole valley of the Mississippi by well-grounded confidence, is still able, after paying fair but moderate salaries, to spend large sums of money in the improvement of her quarantine service. All the fees received in quarantine are spent for its benefit.

The Association passed, without material opposition, an emphatic vote of lack of confidence in the New York station, and there was a decided expression of feeling on the part of many of the western representatives, that it might yet be necessary to find their protection from the negligence or indifference of New York in inter-State quarantine.

Dr. Councilman's description of his recent work in the investigation of malarial fever, and his beautiful demonstrations of the plasmodium of Laveran, occupied one of the evening sessions and was thoroughly appreciated.

Mr. Lomb, of Rochester, who has, in previous years, been so generous a contributor to the resources of the Association, again offers two sums of five hundred and two hundred dollars respectively, for two prizes to be given to the best papers upon the prepa-

ration of healthy food for people in moderate circumstances.

Rudolph Hering, C. E., read a very interesting account of the present aspects of sewerage in its relations to stream pollutions, followed by a statement from Dr. Abbott, of Massachusetts, of the extensive investigations in this direction now going on, under the authority of the State Board of Health.

Altogether, the Memphis meeting may be regarded as one of the most successful in the history of the Association.

A PRECURSOR OF PASTEUR.

In connection with the communication of Dr. Goodale, in a recent issue of this Journal, the profession may be interested to read the following, taken from the *Cronica Médico Quirurgica* of August, 1887, a monthly published in Spanish at Havana:

Dr. Eusebio Valli received the degree in medicine from the University of Pisa, about the year 1778. In 1793, and afterward, he wrote in English a treatise on animal electricity, the phenomena of which were observed by him previously to the naturalist of Berlin. He found, in experiments with frogs, that the motive power of animal electricity was unnecessary to cause muscular action, inasmuch as it could be produced by striking a nerve with any substance whatsoever. He devoted special study to epidemics and infectious diseases, of which cholera and yellow fever were chief. Anatomy, physiology, and hygiene were subjects of his scientific scrutiny.

In 1799, at Leghorn, he made various anti-rabical inoculations, using saliva from mad dogs. One of the combinations was saliva, with gastric juice of the frog: none of the animals thus treated became affected by rabies. These experiments were communicated to the sanitary inspectors of Paris, who ordered the writings of Dr. Valli to be burned.

The views on phthisis expressed in his treatise thereon would have seemed paradoxical but for the rash erudition displayed. Having noticed that smallpox and *la peste* did not exist at the same time in a community, he surmised, in 1785, that the severity of the latter might be lessened by inoculation of variolous contagion. The account of the experiments *in re* upon himself did not show that one morbific agent protected from the other. Similar trials with various materials in different combinations were made, the *modus operandi* of which is given in his note-book on *la peste;* this was published during 1805, while he occupied the Chair of Chemistry, and served as chief physician to the hospital in Mantua. Some years later, still holding rank as surgeon in the French forces, he came to the United States (Philadelphia) to study yellow fever. When told of the danger, he replied that he meant to continue experimentation, as already done in Europe and Asia, trusting to destiny, believing that his end would not be ignoble, and that philanthropists would honor his tomb.

"Convencido del carácter contagioso de la fiebre amarilla, me propongo inocularme con el sudor de los moribundos ó con la bilis de los cadaveres modificando el venem con los mismos reactivos de que me serví en mis ensayos con la peste del Oriente. Si esta escrito en el libro del destino que yo perezca victima de ese grande experimento, mi muerte no será sin gloria y los filántropos de esta region afortunada correrán en tropa á exparcir sobre mi tomba olorosas flores."

Not finding at once material for observation in the States, he went to Havana, where he died from yellow fever a few days only after arrival, in 1816, being forty years of age.

In the eulogy on Dr. Valli, read in Havana, 22d of November, 1816, Dr. D. T. Romay, in a note, says: "I have never seen this disease (yellow fever) terminate on the third day of its invasion: on the contrary, it is noticed that the fever and symptoms then intermit for eight or ten hours, this being a phenomenon which distinguishes it from other fevers."

Dr. Valli's portrait was accorded a place in the Public Library at Havana. Besides being a member of the Accadémia Virgiliana of Mantua, of various medical, scientific, and literary bodies, he was honored by the medical fraternity of Edinburgh. In his life, published by José Valli in 1886, may be found an entertaining and instructive narrative of the experiences and methods in research of one travelled in many lands — Asia, Europe, America — whose large knowledge, solid judgment, and active spirit cause noble emulation in the ambitious student, while his sacrificing of self for others endears him to our human heart.

THE CASE OF THE CROWN PRINCE OF GERMANY.

Recent developments in the case of His Imperial Highness show that the early diagnosis of his German physicians was right, and that other opinions subsequently expressed were wrong. The Crown Prince has been suffering from malignant disease of the larynx. It has been malignant from the beginning, and has steadily spread. It remains now to be seen how soon tracheotomy will have to be performed as a palliative measure unless the bold procedure of extirpation of the larynx is adopted.[1]

In looking back at the reports concerning this important case which have appeared in different medical journals during the past few months, we are forced to the conclusion that scientific journals, like the daily newspapers, are not always to be relied on, and that it is not easy to diagnosticate laryngeal disease *on paper*. We feel, however, that in this instance, the treatment which has followed the mistaken diagnosis has not in any way influenced the natural course of the disease. The diagnosis of malignant disease of the larynx is not, as a rule, difficult to establish. The gentlemen who have had charge of the Crown Prince have unconsciously allowed their scientific judgment to be

[1] Editorial, Vol. cxvi. p. 618. June 23, 1887.

blinded by their Christian feelings and ardent wishes. Their desire to save a life so happy in its domestic relations, and one so important to the future political history of Europe, prevented them from seeing either with their natural lenses or with those of the microscope the true nature of the disease they had to fight.

If the sufferer had been a German peasant by the name of Schultz, instead of Frederic-William-Nicholas-Charles, Prince Imperial, there would not have been, we imagine, two opinions in regard to the character of the trouble. How far State considerations were allowed to influence the *expression* of scientific opinions, of course only those behind the scenes can tell.

From a strictly professional point of view there are some aspects in the management of this difficult case which might "point a moral and adorn a tale." But with these we need not concern ourselves, at least at present. We have now merely to express our regret that medicine is not always the "art of healing," and that a truly noble life is drawing towards its close.

NAPHTHOL AS AN ANTISEPTIC MEDICAMENT.

BOUCHARD has communicated to the French Academy of Sciences the results of a series of researches, from which it appears that naphthol, one of the derivatives of naphthaline, is an excellent antiseptic, surpassing even iodoform.[1]

Kaposi, several years ago, called attention to the value of this agent in the treatment of certain diseases of the skin, and particularly of scabies.[2] He employs naphthol in a ten per cent. alcoholic solution, or in the form of ointment, and says that one or two applications will cure the most inveterate cases of common itch. For this purpose an ointment may be made with one part of naphthol and ten of vaseline. He has had equal success with naphthol in psoriasis, eczema and ichthyosis, and there is nothing better, he says, to allay tormenting itching of prurigo.

Hensinger [3] also speaks in high praise of naphthol as an external agent (alcoholic lotion or pomade) in the skin diseases mentioned above, in lupras erythematosus and in chancres. Under its use sores of a phagedenic character, rapidly take on a healthy action. Van Harlingen, moreover, has seen favorable results from naphthol in obstinate cutaneous affections.[4]

The experiments to which allusion has been made, have led Bouchard to regard naphthol as one of the best and safest of antiseptics. According to these a three per cent. solution markedly retards the development of the typhoid bacillus, as well as that of the bacillus tuberculosis. The same solution is fatal to the microbes of several of the parasitic diseases of animals, and prevents fermentations. Bouchard gives naphthol internally in typhoid fever, and believes that, if it does not abort this disease, it certainly renders its course milder. He regards a dose of forty-five grains (2.50 grammes) a day as realizing the conditions of intestinal antisepsis, and affirms that in such doses there is no antiseptic agent which is more innocuous.[5] This use of naphthol in typhoid fever has been followed to some extent in this country with apparently favorable results.

MEDICAL NOTES.

— Dr. Macaulay writes to the *Lancet*, that he has attended a woman in her seventh confinement, since the removal of an ovarian tumor by Sir Spencer Wells in 1875.

— "I saw at once," said a physician, who had been called in consultation, "that Dr. Pellet's diagnosis was wrong; but as he was in charge of the case, of course it would not do for me to interfere." — "Did the patient die"? — "Oh yes, died of 'professional courtesy,' a very common and fatal disease." — *Harpers' Bazar.*

— Dr. Watkins, inspector of the State Board of Health of Louisiana, has recently examined the prisoners in the parish prison of New Orleans and reports that he found a number of the inmates suffering from acute dropsy of the legs, arms, face and body, due to confinement and insufficient and unwholesome food. Each prisoner is allowed a piece of bread and a pint of tea early in the morning, and one meal consisting of soup, the beef cooked in the soup, and bread. The beef is supplied by contractor at five cents and a half a pound, and has been repeatedly condemned by the resident surgeon.

— The existence of an inflammatory zone about the umbilicus is one of the signs of medico-legal importance in judging whether an infant has lived after birth. In a recent case Dr. Kirk, of Edinburgh, found such a zone and gave judgment that the child had lived. As the result of subsequent investigation of several cases, he came to the conclusion that if a child lives an hour after birth there will be a slight circle of inflammed tissue about the insection of the cord: this zone becomes more pronounced every hour after birth.

— The October number of the *Journal of the Society for Psychical Research* contains the statement: "It will be remembered that the earliest experiments in thought-transferrence described in the Society's Proceedings, were made with some sisters of the name of Creery; and that, though stress was never laid on any trials where a chance of collusion was afforded by one or more of the sisters sharing in the 'agency,' nevertheless some results obtained under such conditions were included in the records. In a series of experiments recently made at Cambridge, two of the sisters, acting as 'agent' and 'percipient,' were detected in the use of a code of signals; and a third has confessed to a certain amount of signalling in the earlier series to which I have referred. This fact

throws discredit on the results of all former trials conducted under similar conditions. How far the proved willingness to deceive can be held to affect the experiments on which we relied, where collusion was excluded, must of course depend on the degree of stringency of the precautions taken against trickery of other sorts, as to which every reader will form his own opinion." The Creery girls are daughters of a Devonshire clergyman, and were from ten to seventeen years of age when the experiments were originally tried. They were among the first in whom so-called "telepathy" was discovered. The record of the experiments with these girls was one of the most interesting chapters in the society's early history, and the proof of their fraud is correspondingly mortifying. It will probably intensify the scrutiny of the other "sentients."

BOSTON AND VICINITY.

— The Newton Cottage Hospital has just been enriched to the extent of $6,000, which is a gift from Mr. J. R. Leeson, of Newton Centre, in memory of his deceased wife, Mrs. Georgia A. Leeson. The money is to provide for the erection of a ward for women and the furnishing of the same. Mr. Leeson had previously contributed to the hospital what is known as the "Margaret Leeson Fund," in memory of his young daughter, who died but a few years ago. This fund is used for the benefit of sick and crippled children and to provide hospital treatment for them.

— Scarlet fever has been remarkably prevalent in Boston during the last few weeks. At a conference of heads of departments with the mayor, held November 11th, Dr. Durgin, of the Board of Health, referred to the increase of scarlet fever, and said that every effort was being made to suppress it. There are probably about sixty cases at present in the city. He also spoke of the cholera scare, but said that the Board would be prepared for any emergency. Dr. Durgin is reported as saying that he has no doubt but that the digging up of the streets had considerable to do with the increase in sickness.

Dr. Rowe, Superintendent of the City Hospital, at the same conference said that twenty-six children were now being treated — twenty for scarlet fever and six for diphtheria — a larger number of children than the hospital has had for some time. A great many applications were being made for admission to the hospital by people outside of the city, which the trustees had to refuse, owing to the lack of room.

The Board of Health have voted to designate all houses in which there are cases of scarlet fever, by the display of a signal, after the manner which has already been pursued in some country districts.

—At the Harvard-Princeton football match at Cambridge, on November 11th, which was very warmly contested, Holden, the captain of the Harvard (victorious) team, who was playing half-back, sustained a fracture of the sternum, with depression of a portion of the bone.

NEW YORK. — CHOLERA NOTES; DEATH OF DR. O'GORMAN, OF NEWARK, NEW JERSEY.

— Mayor Hewitt has taken the Health Officer of the Port, Dr. Smith, to task for the unsatisfactory condition of affairs at Quarantine, revealed by the investigations of the Committee of the College of Physicians of Philadelphia, and the Committee on Hygiene of the New York County Medical Society. In answer to a letter of inquiry from the Mayor, President Bayles, of the City Board of Health, has recently sent the latter a reply, in which, while he declines to discuss the possibility of cholera reaching New York — a matter involving the efficiency of the present Quarantine management, and beyond his jurisdiction — he gives very satisfactory assurances as to the preparations and facilities of the Health Department for dealing with cases of cholera if any should come into the city. He states that the plan of action of the Department has been carefully considered, and seems to be adapted to every possible emergency. Among the preparations made, the ambulances have been reconstructed, provided with tight bottoms and sides, stripped of all upholstery, and supplied with special facilities for safely moving cholera patients. The mattresses with which they were formerly provided have been removed, and rubber beds substituted. Several sets of blankets have also been provided, in order that it may not be necessary to use the same bedding for two cases without intermediate disinfection. The medical corps is well organized, and every man has been carefully instructed in writing what to do if assigned to cholera duty, and how to do it, while, at the hospitals, there are accommodations ready for as many patients as can be expected under the most improbable conditions. In a word, says Mr. Bayles, the Department is so well prepared, that notice of cholera in the city would take no one connected with it by surprise, and occasion no confusion. The preparations also include the provision of two large tanks in the disinfection-house adjoining the Willard Parker Hospital, which will carry a steam-pressure of twenty-five to thirty pounds — an amount far in excess of the maximum requirements of thorough disinfection.

— The death is announced of the eminent Newark physician, Dr. O'Gorman, who was instrumental in sending the first American patients to Pasteur.

Miscellany.

REFLEXES IN NEWLY BORN CHILDREN.

Dr. Julius Farago has published in the *Gyógyászat*, a Hungarian journal, as quoted in the *Lancet*, some observations he has made in Prof. Ebstein's clinic in Prague, on the reflexes of newly born children. Advantage was taken of the lax state of the muscles of the lower extremities while the child was at the breast to test the patellar reflex. Altogether one hundred and seventeen infants under sixteen days old were examined. In all these the patellar reflex was present

on both sides, but the strength of the jerk varied a good deal. In some cases there was merely a slight, short, sudden extension of the leg. In others the jerk was stronger and followed by a series of oscillations. Frequently a transient clonic contraction of the quadriceps was noticed. In some cases a slight contraction was observed in the quadriceps of the opposite leg. Dr. Faragó found that the knee reflex is stronger immediately after birth than during the second week. Premature and badly-developed children weighing less than three thousand grammes, have a weaker knee reflex than children born at term weighing more than three thousand grammes. The abdominal and eyelid reflexes were also noted. The cremaster reflex was present in all the forty-nine male children except nine, and in these the testicles were high or else hydrocele was present.

A DRUGGIST'S MISTAKE.

BROWN was so unfortunate as to fail in business, and his handsome drug store, on the corner of M and N Streets, in the thriving village of Millbrook, has reverted to the original owners. His mistake was that he was too enterprising, too well posted, and ahead of the intelligence of the place.

He bought Smith's Pharmacy just two years ago, one-third down, and the rest on a mortgage note.

Brown had the laudable ambition to advance pharmacy in Millbrook and make it what it should be. He took the *Druggist's Bulletin* and all the other pharmaceutical journals, and several medical journals, which he diligently read.

The medical profession of Millbrook was represented by four old fogies and one homœopath. The medicines ordinarily prescribed by the regular fraternity were such as may be found described in any edition of the "United States Pharmacœpia" prior to 1860.

Brown had a great zeal for new preparations, nice formulæ, and liked to help out the manufacturing pharmacists. The agents and representatives of the great drug houses were uniformly treated by him with great suavity and politeness, as men who were immensely raising the standard of pharmacy, and who deserved to be encouraged as the benefactors of the race.

He bought a full line of their goods. On his shelves, for instance, were seen all of Schieffelin's Gelatine Coated Pills, a couple of hundred dollars being there invested. Then McKesson & Robbins, John Wyeth & Co., Parke, Davis & Co., were not forgotten. He had great faith in Squibb. He was a diligent reader of the *Medical Age*, and ordered a liberal supply of every new thing. When *Strophanthus* first came out he ordered a pound bottle of it from England, which, being expensive, cleaned out his treasury; this bottle, by the way, still remains on those shelves unopened. He bought all of Declat's preparations — "Soda-Phenic" "Iodo-Phenic" syrups, etc., — and those bottles remain to this day untouched, not one of them sold. There are "compressed pills," by the bushel, and "tablet triturates" a full stock, and other new attractions which physicians have requested him to order, but which they never prescribe. Several ounce packages of antipyrine have long in vain waited a customer. Brown early took an interest in this new febrifuge and analgesic and thought that it would be a good thing to have it on hand. He called Dr. Slowman's attention to this most recent purchase. The doctor shrugged his shoulders and remarked: "I do not go in for these new-fangled preparations, I do not dare experiment on any of my fever patients. Give me some Graves' mixture."

In short, Brown's mistake was that he was "ahead of the times" and ahead of the place. It would have been better for him had he been content to dispense chalk mixture, paregoric, castor oil and such like, which were all that his customers seemed to want. Patent medicines he might have sold by the thousands of bottles, but Brown was too conscientious to have anything to do with that in which he had no faith, and he was too well read a druggist to have faith in patent medicines. There was really no demand for all the different kinds of "prepared food," or for all the various emulsions of cod-liver oil with which he encumbered his shelves, and when Brown was obliged to close up business, these preparations were found to be most of them spoiled.

In the last sentence we have indicated the fate that attended Brown. He was obliged "to close up business"; he could not meet his payments, consequently he failed through too much pharmacy. His successor says that he will take warning from Brown's example, and "stick to Epsom salts and castor oil." He will order nothing for the trade that has not been at least twenty-five years before the medical profession.

Correspondence.

SOUR MILK FOR BABES.

BOSTON, October 31, 1887.

MR. EDITOR, — We all know the importance of careful supervision of reading matter likely to fall into children's hands. Such of us as have boys are particularly interested in making sure that anything savoring of the dime novel is eliminated; and many of us subscribe for reputable children's magazines which are published (presumably) for the purpose of affording rational amusement and instruction to the younger generation.

Last evening one of my children, a bright and imaginative boy of nine (pardon this parental estimate) asked me to read to him from a story (which he qualified as "boss") the concluding chapters of which appear in the November number of one of our most popular children's periodicals. I commenced to read, but concluded very shortly that it was time for the boy to go to bed.

What horrors had been depicted in previous chapters I do not know, but here are a few extracts from those which I perused: A party of children are described as digging in an Indian mound — "Aquilla looked into the hole and shuddered. Yet there was nothing horrible in the white arm bones standing out of the earth with fingers all extended . . . the younger boys stood aside while their daring elders lifted the Indian skeleton to the surface. It rattled and dropped in pieces, but they set it with its still articulated spine against a tree, spread the legs out in front of it and placed the skull at its top. The arms hung down sprawling, the long phalange bones on the turf."

This merry scene, so likely to prove conducive to refreshing sleep in children who are passing through the period of second dentition, is concluded by the sudden appearance of a huge and hairy being with a club — a lunatic — who "could bury them in the hole and mind it no more than if he were chopping up a log"! This pleasing party "with motions of his club ranges them in line" and marches them off to unknown horrors.

In the next chapter a little girl knocks at a lonely cabin in the woods, the door of which is suddenly opened by an old woman whose "fierce eyes, and opening and shutting

her mouth with a gnash of two lone teeth," etc., were what the little girl "objected to"! Inside the cabin there was a great frame work made of dark and heavy timbers extending to the rafters, with mystery in its shadows. This proved to be a loom, "draped at the back to within half a yard of the floor, with long threads hanging motionless. But between the threads and the floor were eight boys' legs . . . she felt speechless with fright, as if she were dreaming a bad dream."

These legs belonged to her little brothers and a friend (the same that the hairy being with the club had captured in the preceding chapter), whose "mouths were swathed tight, shut as if from cold, their hands fastened to their sides, and their feet secured."

Soon the hairy one appears and proposes (as a punishment for desecrating the mound) that the offenders 'thumbs be at once cut off and buried with the disturbed skeleton. Fortunately the threatened mutilation is prevented by "Uncle Roseladies" (apparently a sort of Rollo's father and Belfast Spider combined in the person of a verbose old gentleman), who knocks out the hirsute lunatic in one short but spirited round, and thus terminates what might have proved a disagreeable episode.

Now I ask if this is suitable reading for children? Why not return to the Bloody-shadow-of-the-double-handed-sword-or-the-cross-of-the-Antilles style of literature which we used to surreptitiously absorb in boyhood days before the present fashion of children's periodicals came in vogue? In conclusion I quote from the prospectus of the *Wide Awake* (ominous title!) magazine:

"Think of a life not only unhurt by wrong reading and pictures, but helped by right reading and pictures all the way through"! Very truly yours,

JOHN SMITH, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 5, 1887.

Deaths reported 2,079: under five years of age 721; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 425, consumption 208, acute lung diseases 208, diphtheria and croup, 208, typhoid fever 60, diarrhœal diseases 57, scarlet fever 38, malarial fever 25, cerebro-spinal meningitis nine, puerperal fever eight, whooping-cough seven, erysipelas five. From scarlet fever, New York nine, Brooklyn and Boston eight, each, Philadelphia and Somerville three each. Fall River and Chelsea two each, Portland, Pittsburgh and Malden one each. From malarial fever, New York and New Orleans seven each, Brooklyn six, Philadelphia and District of Columbia two each, Baltimore one. From cerebro-spinal meningitis, New York and Philadelphia three each, District of Columbia, Worcester and Somerville one each. From puerperal fever, Philadelphia, Baltimore and District of Columbia two each, New York and New Orleans one each. From whooping-cough, Baltimore four, New York and Brooklyn one each. From erysipelas, Brooklyn two, New York, Philadelphia and Newburyport one each.

In the 20 cities and larger towns of Massachusetts with an estimated population of 979,911 the total death-rate for the week was 20.40 against 19.82 and 18.93 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending October 22d, the death-rate was 19.8. Deaths reported 3,502: infants under one year of age 797; acute diseases of the respiratory organs (London) 370, scarlet fever 117, whooping-cough 62, measles 59, diarrhœa 56, fever 52, diphtheria 38, small-pox (Sheffield seven, Bristol one) eight.

The death-rates ranged from 15.8 in Halifax to 26.4 in Manchester; Birmingham 17.7; Hull 19.6; Leeds 22.7; Leicester 20.4; Liverpool 19.6; London 19.4: Nottingham 17.2; Portsmouth 18.5; Sheffield 19.3.

In Edinburgh 20.8; Glasgow 18.4; Dublin 24.1.

The meteorological record for the week ending November 5, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 5, 1887, TO NOVEMBER 11, 1887.

GREENLEAF, CHARLES R., major and surgeon. Par. 8, S. O. 248, A. G. O., October 25, 1887, directing Surgeon Greenleaf to visit the recruiting depots and rendezvous at certain places, is amended to include Davenport, Iowa; Quincy, Ill., and Evansville, Ind. S. O. 257, A. G. O., November 4, 1887.

LORING, LEONARD Y., captain and assistant surgeon. Ordered for duty at Fort Mojave, Ariz. Ter., upon the expiration of his present sick leave of absence. S. O. 258, A. G. O., November 5, 1887.

PERLEY, HARRY O., captain and assistant surgeon, now on duty at Fort Wayne, Mich. Ordered for temporary duty with troops stationed at Highwood, near Chicago, Ill. S. O. 258, A. G. O., November 5, 1887.

IVES, F. J., first lieutenant and assistant surgeon. Granted leave of absence for one month, to take effect on or about the 15th inst. S. O. 113, Department of Platte, November 5, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 12, 1887.

HEYL, T. C., surgeon. Detached from the "Marion," proceed home and wait orders.

CRAIG, T. C., passed assistant surgeon. Detached from the "Marion," proceed home and wait orders.

WELLS, H. M., medical inspector. Detached from the "Trenton," proceed home and wait orders.

PECK, GEORGE, medical director. Ordered to Washington, D. C., as member of Examining Board.

AYRES, JAS. G., surgeon. Ordered to the "Galena," to relieve Surgeon F. L. DuBois.

DUBOIS, F. L., surgeon. Detached from the "Galena," proceed home and wait orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING NOVEMBER 12, 1887.

FESSENDEN, C. S. D., surgeon. Detailed as chairman of Board for the physical examination of officers of the Revenue Marine Service, November 1, 1887.

MEAD, F. W., passed assistant surgeon. Detailed as Recorder of Board for the physical examination of officers of the Revenue Marine Service, November 1, 1887.

BEVAN, A. D., passed assistant surgeon. Relieved from duty at Portland, Ore., ordered to Marine Hospital, New York, November 2, 1887.

CARRINGTON, P. M., assistant surgeon. Relieved from duty on Revenue Steamer "Rush," ordered to Marine Hospital, San Francisco, Cal., November 2, 1887.

PERRY, T. B., assistant surgeon. Relieved from duty at Marine Hospital, San Francisco, Cal., ordered to assume charge of Service at Portland, Ore., November 2, 1887.

GOODWIN, H. T., assistant surgeon. Relieved from duty at Norfolk, Va.; ordered to Marine Hospital, New Orleans, La., November 5, 1887.

WYMAN, WALTER, surgeon. To proceed to Louisville, Ky., and Memphis, Tenn., as inspector, November 2, 1887.

URQUHART, F. W., passed assistant surgeon. Relieved from duty at Cape Charles Quarantine; ordered to Norfolk, Va., November 6, 1887.

MAGRUDER, G. M., assistant surgeon. When relieved, to rejoin station at Chicago, Ill., November 3, 1887.

DEATH.

Died in South Boston, November 12, 1887, Charles Edward McGowan, M.D., M.M.S.S., aged thirty-six years.

CASES ILLUSTRATING THE LATE MANIFESTATIONS OF CONGENITAL SYPHILIS.[1]

BY ABNER POST, M.D.

THE heredito-syphilitic infant is very likely to cease to show symptoms of his disease before the end of the second year. Apparently, many patients show no further signs of the disease; others go on without manifestations of the disease until about the age of puberty, or later. With others, the disease manifests itself at irregular intervals, so that they present a history of nearly continuous trouble, or of more or less frequent outbreaks. The first two years, then, comprise the early symptoms of hereditary disease, those that correspond with the secondaries of acquired syphilis; and the symptoms that come later, may be classed as late hereditary disease.

The evidences of late hereditary syphilis may consist in the evidences of previous lesions, in the modifications of growth that take place under the influence of the disease, and in lesions still active at the time when the patient appears for advice.

The evidences of previous trouble may vary very greatly, according to the age of the patient, and the character and severity of previous lesions.

It is an interesting question whether the later forms of the disease ever occur without the previous occurrence of earlier — infantile — manifestations. Such a question is equivalent to the question whether acquired syphilis ever shows its late forms without any early secondary manifestations. It is certain that we find late forms of the disease, both acquired and hereditary, in which we fail to find any evidence of earlier trouble, or, at best, but very questionable evidence, and certainly, cases in which previous disease is positively denied.

The late hereditary form of the disease assumes the same protean aspects as do the later forms of the acquired disease. Probably all the forms of acquired syphilis may appear in the hereditary disease. It presents the same difficulties of diagnosis, and is amenable to the same treatment as the more familiar acquired disease. I have selected a few cases which will serve to emphasize some of the peculiarities of the hereditary disease in its later aspects, and to illustrate some of the advantages of treatment.

Some of my cases are defective, in that disease in the parents is not fully established. This would be a serious objection were I attempting to prove that syphilis may be inherited. That syphilis is transmitted from parent to offspring, it is unnecessary to prove. My cases all show, at least, that the disease existed very early in the life of the child, so that they have essentially modified its growth, and its hereditary character, when not proven, is, at least, exceedingly probable.

CASE I. M. Her father, now dead, was known to have had syphilis before the patient's birth, according to the mother's story. The child was first seen by the writer in 1883, at the age of eight, when she complained of several points of periostitis, circumscribed to round spots, on various bones. She also showed cicatrices where similar spots had gone on to suppuration and extrusion of bone. Some of these spots were still open; others showed cicatrices adherent to the bone. There were also other large, circular, thin, white cicatrices not attached to bone. She was, in general, small for her age. Her mouth showed, at the corners, well marked radiating cicatrices, of the existence of which the mother was ignorant. This fact, that the mother had never noticed the scars, will, perhaps, illustrate their insignificance. At the same time, they were, and still are, exceedingly well marked. The mother recalls the fact that the child had an exceedingly sore mouth when about two years old. Of the cicatrices adherent to the bone beneath, the oldest, on the dorsum of the right hand, was said to have originated at the age of eighteen months — about the time at which the child was weaned.

She was put upon specific treatment, and did well, the sores healing, and the periostitis disappearing, but, by the advice of friends, she was transferred from my care to that of a man who was able to promise more — a well-known irregular practitioner, a vegetarian — who took away her specific medication, and under whose care she rapidly grew worse. In the fall of 1884, when nine years old, she returned to me, with the right side of her face hideously swollen. The swelling was due to disease of the superior maxilla. The upper teeth on the left side were loose, and several were removed. The bone was, however, dead, and she entered the City Hospital on November 10, 1884, in the service of Dr. Cheever, who removed through the mouth a portion of the upper jaw, which contained all the teeth of that side, permanent, as well as deciduous. The wound reopened, and discharged an offensive pus for some time; a few bits of bone were exfoliated, and the wound healed soundly, and has given little trouble since, save such as was inevitable from the loss of bone, which threw nasal and oral cavities together. During the healing of the wound, there were various threatening symptoms, which, I feel sure, would have gone on to further destruction of bone but for vigorous treatment. Since the cicatrization, the symptoms have been very few — some slight fissures at the nasal orifice, some indefinite rheumatoid pains, a slight vaginitis — none of which could have been considered syphilitic had they occurred in any other child, and localized tender spots over various bones, which made us fear further trouble.

She has continued under treatment almost constantly, increasing the dose as some slight symptom excited my apprehension, and varying from iodides to mercurials, as circumstances seemed to indicate.

At present, she is a large girl of twelve, nearly the height of her mother, well developed and strong — a marked contrast in general condition to the child, as I saw her, between four and five years ago.

She illustrates most completely the advantages of persistent treatment. Outbreaks of periostitis were controlled by the anti-syphilitic remedies. When one such attack was allowed to go without adequate treatment, the bone died, and its removal was obligatory. A return of treatment was followed by equally happy results, as at first. I can but feel that, in her case, the favorable condition is the direct result of medication. In this case, there can be no question of the nature of the disease, and of its hereditary character.

CASE II. Miss C. Father and mother both dead. Father died at about forty, in an insane asylum, of general paralysis. When first seen, the patient, seven-

[1] Read before the Boston Society for Medical Improvement, October 24, 1887.

teen years of age, was suffering from extensive necrosis of both tibiæ. One leg was greatly shrunken and contracted about the knee, rendering it impossible to straighten that leg. The bone was exposed in several places. At least, two-thirds of the skin below the knee was either ulcerated or formed of cicatricial tissue, the result of previous ulcerations. The other leg was in a similar condition, though less marked. These spots had all commenced as periostitis, with great pain, gradually going on to ulceration and exfoliation of bone. This condition had commenced before the age of four. Previous to that time, no history was obtainable. On other bones, this young woman presented various spots of periostitis.

In general, she presented an exceedingly immature aspect, and might easily have passed for several years below her true age. The head presented a most marked appearance from the height of the forehead, which deserved the epithet Olympian. There was also a tendency to especial thickening about the frontal eminence, while the features were almost infantile. The legs and the spots of periostitis were the seat of atrocious pains.

Under large doses of the iodides, with small doses of mercury, the pains vanished, the ulcers partially cicatrized, and the patient was able to walk somewhat, and enjoyed comparative comfort far beyond my highest expectations. Later, pains attacked her head — periostitis was evident on the frontal bone. The patient became unmanageable, and absolutely refused the iodides, the periostitis went on to destruction of the bone and the loss of the greater part of the frontal bone above the orbital ridge.

In this case, it is not so easy to establish absolutely either the specific or the hereditary nature of the disease. The father died at an age a little early, perhaps, for general paralysis, but his malady was not regarded as of specific origin by the attendants, though they would not say that it was not syphilitic.

Simultaneous disease of so many bones is rare, unless from syphilis and destruction of the skull, unless from traumatism, must be exceedingly rare, unless syphilis is a cause.

This case illustrates very well the effect upon growth of the disease. The child is not merely stunted — it remains in many ways undeveloped, and appears, both in bodily and mental development, behind its actual years. This condition is best described under the term infantilism, and will be further illustrated.

The way in which the disease has stuck to the bones, leaving all other parts of the body untouched, is very noticeable. Although large portions of the integument have been destroyed, it is only a secondary process, the local trouble commencing always with the periosteum, the ulceration taking rise below the true skin. The effect of medication is also strikingly illustrated. Of great service when properly taken, the disease ran its course freely when the patient refused further adequate treatment.

Infantilism is marked much more strongly in the following case, which may, perhaps, be considered an extreme instance of such stunted growth. The case also shows the concentration of the disease upon the bones, and also a tendency, at the same time, to attack the nervous system.

CASE III. E. Consumption in mother's family; father in poor health. Is the youngest of several children; others well. Was born at full term, but weighed four pounds only. At three years of age, weighed twelve pounds. When quite a child had a rash, which was general. Was taken to a hospital, and mother overheard the doctors say the eruption was syphilitic. Has always complained of pain in different parts of the body, like rheumatism.

April 9, 1884, was at the Children's Hospital with a large periosteal swelling at the lower ends of both humeri; one of these swellings had broken, and a sinus communicated with the bone. The other swelling was painful, and exceedingly tender. No other active trouble. In the fall of 1886, the following note was made:

'She is twelve years old, but, when standing by the side of a child of six, the height of the two children, as well as the general development, is practically the same. Her head shows a massive forehead, with protruberant frontal eminences. Her features were infantile. Nasal bones flattened. Her lips fell in, like those of an old woman whose teeth are gone, and alveoli atrophied. Her corneæ showed several opaque spots, and there was a discharge from one ear. Her teeth presented several peculiarities, too numerous for description. The upper central incisors were stumpy and notched in the centre, while the lower central incisors were remarkably small, and deformed by a similar, but more marked central notch. There seemed to be, also, a lack of development in the alveolus of both jaws — a deficiency which explained the falling in of the lips. The lower end of one humerus was thickened and enlarged, and presented a cicatricial depression, adherent to the bone below. Through the ulceration, of which this cicatrix was the remains, bone had evidently been exfoliated. The other humerus presented, at the corresponding spot, a considerable thickening, and there was a very evident inflammation of the periosteum in progress.

In February of the present year, she complained of "nervous spells." Said that she felt as if she was in a boat, which was rocking and going to tip over. Everything seemed going round. These attacks always occurred at night, and lasted about an hour, and were always followed by nausea and vomiting. There was no loss of consciousness. The attacks occurred three times during one week. Under iodide of potass they entirely disappeared. She eat prodigiously, and grew fat. During the spring she had a sudden attack of deafness, for which no reason could be assigned, and which disappeared.

The nervous attacks were never seen by any one save the family, but they caused the child great suffering. She spoke of them with the greatest dread while they lasted, and, after they ceased, with thankfulness at their departure. The attacks certainly resembled the attacks of giddiness which occur in certain cases of acquired syphilis with cerebral manifestations, and they vanished entirely under the influence of the iodides.

The source of the disease in this child is not evident, but the diagnosis is, I believe, beyond dispute.

A more marked case of cerebral symptoms in hereditary disease occurred in the following case:

CASE IV. H. S. The patient is a Russian Pole by birth. His English is very imperfect, and it is exceedingly difficult to converse with him. He knows very little of his parents. States that he was well up to December, 1885, when, at the age of eighteen, he was

suddenly taken with an epileptiform convulsion, which occurred in the night, and of which he had no recollection in the morning. The convulsion consisted of spasmodic movements in left arm and leg, and frothing at the mouth. A few days later, he had another attack, and was found on the floor in the morning (December 18th), and was sent to the hospital on the same day. Entering the nervous and renal service at the City Hospital, he complained of pain in left arm and leg. Temperature 99.4° pulse 80, respiration 20. Movements of left hand irregular and spasmodic. On protruding tongue, marked twitching of muscles on left side of nose and mouth, and, on drawing over corner of mouth, there was some spasmodic twitching of muscles at lower border of chin. Reflexes normal; heart normal. Urine normal, acid, 1010; no albumen. Discharged on the 21st, three days afterwards, *well*. Subsequently, he continued well up to June or July, 1886, when he noticed several small bunches on neck, forehead, and various parts of the body, especially about the head. In October, he re-entered the Hospital, this time in the surgical service. To the eye, he presented an exceedingly curious appearance from the swellings about the skull. The largest and most prominent one at the date of admission to Hospital was situated at the middle of the forehead, extending down over the bridge of the nose, and reaching nearly the size of an ordinary hen's egg. On each side of the forehead was one a little smaller.

In general, he may be said to be a little under size, though not strikingly so. Examination disclosed several other swellings, in addition to the bunches mentioned, scattered over the skull, and one on the clavicle. The bunches were not painful or tender, and did not fluctuate, except that the largest swelling, that in the middle of the forehead, gave some pain, as it could hardly fail to do from its size alone.

On October 6th, examination of the urine, which, it will be remembered, was recorded as normal in December, 1885, nine months previous, showed it to be pale, slightly acid, 1010; slight trace of albumen, with hyaline and granular casts. He passed forty-five ounces in twenty-four hours.

On November 3d, urine was 1004½. Slight trace of albumen, with hyaline and fine granular casts.

February 9th. Passed ninety-seven ounces of water. Under treatment, some of the lumps grew smaller, some suppurated. He grew better, and again worse. Ulcerations formed on his legs. He finally entirely lost hearing. Had intense headache, continued vomiting, and he died worn out. No autopsy obtained.

When I first saw him, examination disclosed faint cicatrices radiating from the angles of the mouth. The upper central incisors were worn smooth, showing a worn and blunted surface at each corner, and a sharp edge at the centre, such as would be presented by a worn-down notch. Various cicatrices over different portions of the body. The Hutchinsonian teeth were, in this case, obliterated by the wearing from persistent use. The lower teeth were similarly worn, having sustained a loss of substance fully equal to that of a man of forty-five or fifty.

This case is in some respects the most interesting of the series. The cicatrices at the corners of the mouth, and the worn-down Hutchinsonian teeth, mark the case as hereditary. Gummy periostitis is not a very common form of disease; at least, it has seldom fallen under my notice. The epileptic attack would not be a very rare occurrence in acquired syphilis. As a result of hereditary disease, it is not very frequent, but the renal disease is even more exceptionable as a result of syphilis, either acquired or hereditary.

Case V. Kate C., aged ten. So far as the mother knows, there have been no venereal accidents in the family. She has herself always been well. Her husband had, six years ago, a paralytic attack. Without known cause, he was attacked with pain in the right thumb, and his right arm gradually became helpless. Then the left arm was similarly affected. The paralysis is not complete, and the two arms are unequally affected. No other paralysis exists. Her first four children were still-born at seven and eight months. The fifth child was the patient in question, now ten years old, who had snuffles when a baby, and has always been sickly. Her sixth and seventh children she says, are strong and well, but they have never been seen. Here we have an anomalous nervous affection in the father, and a series of miscarriages preceding the birth of the first living child — a history which does not prove syphilis, but would render its existence exceedingly probable.

The child was in the Hospital, under the care of various surgeons, for necrosis of the tibia. Her corneæ were both hazy. Her upper central incisors showed, instead of a notch, a central portion where the Hutchinsonian notch ought to be, of a dark-colored substance, the dentine uncovered by enamel. She showed a curious deformity in a deficiency in the superior alveolar arch at the anterior portion, so great that when the teeth were brought firmly together, the upper and lower incisors were so widely separated that the little finger could nearly be introduced. The tibia was several times operated upon before it was brought to heal. During her stay in Hospital, she had an attack or two of erysipelas, and some furuncles.

In these cases, the bones are specially the subject of disease, while the manifestations on the skin are either ulcerations consecutive to disease of bones, or active processes are wanting. The next case to which I wish to refer shows exactly the reverse; that is, the trouble is principally located upon the skin.

Case VI. M. D. I saw the boy first in November, 1886; referred to me by Dr. H. W. Cushing. His father is a man of dissolute habits, who has deserted his child. Though no reliable history of syphilis can be elicited, he certainly belonged to a class which seldom escapes it. Mother died when the boy was three years old, of quick consumption, but without a cough. No history of the child as an infant until he was six months old. The first thing noticed by the aunt who now cares for him was a dactylitis, which came on at the age of two-and-a-half years, and still exists.

When first seen by me, there was a marked dactylitis of the middle finger of the right hand, and of the middle finger and thumb of the left hand. There were a few white, depressed, irregularly-rounded cicatrices on the arms, of perhaps the size of a nickel. On the face, neck, right cheek, back of left hand, both arms, behind both knees, and near the head of the tibiæ, were ulcerations partially covered with prominent, dark, thick crusts. Upon the parotid region, particularly, the skin about the ulceration was infiltrated and partially undermined. The left ankle was greatly swollen, reddened on the inner aspect and

apparently the subject of deep-seated disease. On its outer aspect, it was covered with thick crusts, like those on various other parts of the body. The whole shaft of the left tibia was somewhat enlarged. The boy had been under treatment by cod-liver oil without benefit. His appearance was so revolting, that, at school, he had been given a seat in the entry, and finally forbidden to attend school at all.

The diagnosis of congenital syphilis seemed most favorable and was reached on the character of the bony lesions in the fingers, and of the ulcerations, with their resulting cicatrices and crusts. Dactylitis exists from other causes than syphilis, but, united with other suspicious lesions, it can but add to the probability of syphilis. The cicatrices could hardly be due to any other cause than syphilis, and the existing lesions on the skin resembled closely ulcerated tubercles of acquired syphilis, though more numerous and more freely suppurating than ordinary. The failure of cod-liver oil to ameliorate the condition added its weight in diagnosis. The child was dosed with iodide of potash, and his numerous sores were dressed with unguentum hydrargyri. He remained under treatment four months, and was watched by the class at the Dispensary. During that time he took his medicine with a certain amount of regularity, but it was difficult to supply sufficient mercurial ointment to keep the sores covered. The improvement in the boy's condition was marked from the first, though, perhaps, not very rapid. When I ceased to attend at the Dispensary, I lost sight of the boy for a time. Seen again on October 22d. He has had no treatment for five months. During that time, his ulcers have remained stationary. He is fat and hearty — greatly improved from the condition in which I saw him first. His aunt says he never improved so much as when taking the iodide. It is to be noticed that he lives on equality with his aunt's family, and in the closest intimacy with a little cousin some years younger, but none of the family have ever suffered in the slightest, the danger of infection being absolutely nothing from a child in so advanced a stage of the disease.

The following case was brought to my attention only two days ago, simultaneously by Dr. DeBlois and Dr. H. L. Smith, of the Superintendent's office of the Boston City Hospital. She shows a decided concentration upon the throat, while both skin and bones are free from active trouble.

CASE VII. S. J., twelve years old. Father dead of phthisis. Mother suspects that he may have had syphilis, but can give no symptoms. He was a gambler, and, in general, a doubtful character. The mother, in giving her own history, admits nothing that points to syphilis, but her character differs from that she attributes to her husband. There is *nothing doubtful* about it. As to the child, the mother gives the following history:

When three months old, the child had a "wheezing." This became better, but, at fifteen months old, she had a "catarrh," characterized by a discharge from the nostril. At two years old the child could talk pretty well, not being hoarse, although she sometimes complained of sore throat, and was short of breath. About a year ago lost her voice, though the voice is at sometimes better than at others. Has been growing deaf in right ear during the past six months.

Examination shows a child of good size for her age, of high forehead, with so marked an enlargement at the frontal eminences on each side as to make the head practically square-cornered in front. The nose is slightly flattened, but not very markedly. The right central upper incisor is slightly notched, and when the teeth are brought together, the incisors fail to meet, being separated, at least, an eighth of an inch. Nothing else noticeable about the bony frame-work. Over the left frontal eminence is a cicatrix, and, at the corners of the mouth, are faint radiating lines of cicatrix, which are noticeable only on careful inspection, but are unmistakable. The only other cicatrices discovered are three or four on the lower part of the trunk or buttocks behind. These scars are white, irregularly rounded, from an eighth to a quarter of an inch in diameter.

There is a slight opacity in each cornea, and the child is too deaf to hear any ordinary conversation—a deafness which has come on gradually during the past year. Her voice is scarcely more than a hoarse whisper. There is also increased rapidity of respiration and some dyspnœa. Dr. DeBlois reports extensive cicatrization of pharynx and larynx, and swelling of both arytenoids, with anchylosis.

Without attempting to discuss the symptoms that should make one suspicious of hereditary syphilis in a child past infancy or a young adult, I wish to say a word or two in regard to some of the symptoms prominent in these cases. Although the Hutchinsonian teeth are well-known there are facts in regard to their life history not so well-known, as pointed out by Mr. Hutchinson. The teeth at first do not always possess the typical notch, but the place which will later become a notch is filled with an imperfect and discolored dentine as seen in Case V. In later years the tooth wears down until the notch is destroyed — a process exemplified by Case IV.

The girls, Cases V and VI, also shows another peculiarity mentioned by Mr. Colman, the dentist, who examined the first cases with Mr. Hutchinson, viz., a lack of developement of the alveolus of the upper jaw.

He is quoted by Mr. Hutchinson in his first paper on the deformity of the teeth as follows: "In nearly every case there is a deficiency in the superior alveolar arch at the interior portion, so great in some patients that the upper and lower incisions are a considerable distance apart from each other when the mouth is shut."

I have laid some emphasis upon the cicatrices at the corners of the mouth. The lips of babies of a few weeks are often covered with erosions, whence flows a virulent fluid which forms yellow crusts; that alteration is usually too superficial to leave traces. Often after the age of three months the malady causes upon the lips a certain number of fissures which may attain the depth of one and even two millimetres on the upper lip on each side of the lobule and on the lower at the median fissure, frequently also at the commissures. "There are few syphilitic infants who escape these syphilides of the labial commissures." [Fournier]. In this last spot the loss of substance is much more extended. These fissures cause cicatrices in those who bear them, which are more apparent the deeper, and of longer duration the syphilides have been.

The cicatrix may be scarcely or not at all visible upon the mucous membrane since the lesions upon the

mucous membrane heal with less apparent cicatrices than those upon the true skin.

These cicatrices are so slight that they are only visible on close inspection. No deformity is present, and the non-medical friends may not know of the existence of such lesions. These cicatrices at the commissures of the lips are considered as quite characteristic of inherited syphilis, and I believe correctly, but I am far from saying that similar scars cannot be due to other causes than syphilis. I have seen one case in which scars in that spot were due to another cause. They exist in the person of a lady who, when hardly more than an infant, had scarlet fever at the same time with two older sisters, with a very sore throat which throat was treated by applications of nitrate of silver which she resisted with all her strength, and the applications were undoubtedly applied to all the vicinity. She is described as having had an awful mouth and has carried these scars ever since, and one might be pardoned for thinking them syphilitic. Close examination shows that the scars in this case lack the linear form characteristic of the disease.

Cases in which there is disease of several bones are open to suspicion and should lead to investigation. I am by no means ready to say that necrosis or caries may not exist in several bones in a child or young adult without that child or young adult being a victim of syphilis, but I think the chances are many to one that syphilis would be at the bottom of such a case. That probability is still stronger if the symmetrical bones are attacked. The terminal extremities of the long bones are specially liable to suffer. I am inclined to think that the necessity for treatment in these late cases is not fully appreciated. They need to be treated in the same way and as carefully as the acquired cases, and perhaps even more persistently. Treatment was not universally successful in the cases I have narrated. The young man, Case IV, died, a result almost inevitable from the grave character of the lesions, but in other cases the results of treatment were brilliant, and I think I may say the success depended in great measure upon the faithfulness with which it was carried out. Practically the same plan that is pursued in so-called tertiary disease in the adult is adapted to these late inherited lesions; that is, a treatment into which the iodides enter largely in conjunction with mercurials. In some cases the iodides need to be given in large doses.

NERVOUS SYMPTOMS FROM OCULAR DEFECTS. THEIR RELIEF BY MECHANICAL AND MEDICINAL MEASURES.[1]

BY R. W. AMIDON, M.D., NEW YORK.

The subject of nervous symptoms from ocular defects has been voluminously written upon by ophthalmologists, but it is from the standpoint of a neurologist that it will be now approached.

That such a presentation may be somewhat novel and perhaps instructive is my only apology for writing upon a subject so trite.

People suffering from symptoms plainly referable to the eyes generally consult an ophthalmologist at once; but in a certain proportion of cases, the relation between the nervous symptoms and the ocular defect not being very clear, the general practitioner or the neurologist is consulted. It is this class of cases with which the present paper has to deal: Cases in which the phenomena are chiefly sensory and resemble the symptoms of organic or functional disease of the nervous system. In selecting these cases care has been taken to exclude those of organic disease of the nervous system and eyes, and cases of functional disease where the symptoms were of extra-ocular origin.

The most common nervous symptoms referable to ocular defects are variously located headaches, occipital, vertical, temporal, frontal and general; various paræsthesiæ about the head, back of neck, shoulders and back; neuralgias, hemicrania, vertigo, staggering, diplopia, nausea, confusion, ptosis, photophobia, etc.

The ocular defects giving rise to these varied symptoms are, insufficiency, hypermetropia, myopia, astigmatism and presbyopia, either alone or in simple or very varied combination.

After a careful scrutiny of many cases, one hundred and sixty-two were found with sufficiently perfect histories to deduce the following conclusions:

(1) Patients in whom insufficiency of the internal recti muscles is a prominent defect are very apt to suffer from sensory disturbances in the occiput, nucha, shoulders and back. These disturbances may take the form of acute or dull pain, a heavy pressure feeling or various paræsthesiæ, hard to describe and at times exceedingly annoying to the patient.

(2) Patients in whom insufficiency of the other recti is prominent do not appear to be subject to occipital disturbance, but, next to asthenopic symptoms, which are almost always present, seem to suffer most from vertigo, diplopia and confusion.

(3) In hypermetropia and hypermetropic astigmatism the most frequent complaint, aside from asthenopia, is of frontal headache.

(4) In myopic and mixed astigmatism, frontal, temporal and general headaches are about equally common.

(5) In cases combining hypermetropia and myopia with presbyopia, frontal, temporal and occipital headaches and vertigo are present in about equal proportions.

(6) In pure myopia and presbyopia nervous symptoms are seldom prominent.

The natural inference to draw from these facts is that where there are sensory disturbances about the occiput and nucha, particularly if made worse by use of eyes, the internal recti muscles should be tested with a fair prospect of finding them weak, provided the symptoms alluded to do not depend upon organic disease of the nervous system or acid, flatulent dyspepsia.

When vertigo, unsteadiness, diplopia, and confusion with asthenopic symptoms are prominent, one can look with considerable confidence, in the absence of organic nervous or vascular disease and anæmia, for a disturbance of the equilibrium of the superior, inferior or external recti muscles. When frontal headache with asthenopia is prominent, strongly suspect hypermetropia or hypermetropic astigmatism, unless constipation, catarrh of the frontal sinus or Bright's disease is present.

In general headaches or different combinations of frontal, vertical, temporal and occipital varieties, in the absence of other provoking causes, always suspect and examine the eyes.

Many factors, besides use of the eyes, aggravate

[1] Substance of a paper read before the New York Academy of Medicine, Section on Neurology, October 14, 1887.

these various paræsthesiæ; excitement, worry, debility, fatigue and exposure to hot or confined air.

The relief of nervous phenomena due to ocular defects by the use of accurately adjusted correcting glasses is almost too well known to refer to.

I must, however, make one exception to this statement, and that is in respect to the treatment of insufficiency of the recti muscles. My opinion is that correcting prisms, when properly used, are much more often curative than is generally thought.

In the first place adjuvant medicinal treatment is very often utterly neglected. Experience teaches me that sufferers from insufficiency of the ocular muscles are seldom if ever well. An anæmic condition is often present; a neurasthenic, debilitated state from overwork, worry, excesses, confinement, etc., is very common; dyspeptic ailments are often seen, while the various paræsthesiæ, from which the patient suffers, induces a frame of mind, certainly despondent and hypochondriacal and often bordering on the melancholic.

For the anæmic condition I prescribe iron with bitter tonics, nux vomica, quinine or quassia and perhaps a laxative as belladonna, rhubard or aloes in small doses.

In the neurasthenic and debilitated state an anæmia is often present and must be treated. Other tonics than iron seem at times indicated, and phosphorus, cod-liver oil, and occasionally alteratives such as arsenic, mercury or iodide of potassium seem beneficial. Laxatives are often needed and mild vegetable ones should be employed.

Plenty of digestible, nourishing food is needed in all these conditions, but in none more than in this state of neurasthenia, which so often means only mal nutrition. Supplemental meals should be insisted upon if needed and, unless contraindicated, some alcohol in the form of milk punch or egg nog should be added to the dietary. At bedtime particularly, is this indicated, to help relieve the partial insomnia from which these patients often suffer. This insomnia is sometimes quite marked and annoying and demands special treatment. Chloral and the bromides should generally be avoided, the former because of its irritant action on the eyes, and the latter of their debilitating effects.

Our chief reliance should be upon simple measures, such as food or alcohol, or both at bedtime, and these failing, mild narcotics, such as assafœtida, camphor, valerian or cannabis, should be tried, opium being reserved for rebellious cases.

Dyspepsia occurs alone or with the foregoing condition; the most common form seen in these cases being the acid and flatulent variety. The most prompt relief is obtained from a diet rather free from starch and sugar, and the use of dilute nitro-hydrochloric before or an alkali after eating or both. A condition of intestinal dyspepsia often calls for carminatives and laxatives which, as a general thing, should be gentle and vegetable. Rhubarb, aloes or podophyllum in small doses, assisted by belladonna should suffice.

The melancholic tendency of these patients is very often relieved by treating the anæmic, neurotic or dyspeptic condition so often present at the same time. When general treatment fails, correction of the existing ocular defect often completes the cure. Occasionally, the depression is so marked as to call for a mild cannabis and opium course.

A rheumatic element sometimes crops out, often in conjunction with the neurasthenic state, and it should be met by the oil of wintergreen, the salicylates, alkalies or counter-irritation.

Instability of the circulatory apparatus, so often seen in these cases, should be met by general tonic treatment and digitalis.

The patients, therefore, presenting themselves with an insufficiency of the recti muscles, are carefully examined and then put upon appropriate medicinal treatment as outlined above, each case being studied by itself. Sometimes a few days of this treatment will appreciably lessen this weakness of the recti muscles, particularly if rest be super-added.

When, after two or more examinations glasses are ordered, the refractive errors, if there are any, are properly corrected, while prisms, representing about three-quarters of the insufficiency in the case of the interni or externi, and equal to the entire insufficiency in the case of the superior or inferior recti, are added.

The amount of the insufficiency varying with the general health and strength, examinations of the recti should be made from time to time, when if the patient's general condition fails, the insufficiency will increase, and perhaps demand stronger prisms, while, if health and strength be regained, the insufficiency will rapidly lessen and disappear in favorable cases, rendering a discontinuance of the prisms possible.

This latter has been the result in at least three-quarters of my cases.

With respect to medicinal treatment, almost the same remarks will apply to those cases where errors of refraction only exist. All will attest that these errors of refraction often produce no symptoms until the nervous resistance or general health break down. Then all of a sudden a hypermetropia or astigmatism which has for years lain dormant, will suddenly give rise to most distressing symptoms.

As a counterpart to this, we see cases in which correcting glasses, worn for months, are finally discarded as unnecessary, the nervous strength and general health having been sufficiently restored to allow the patient to ignore strain produced by an ocular defect.

Medicinal treatment is of extreme importance in this class of cases also, and is, I think, too commonly ignored. The general line of treatment is the same as in cases of insufficiency, less reliance being placed upon special tonics such as strychnia and more upon a general tonic course.

A CASE OF RECURRENT PARALYSIS OF THE MOTOR OCULI.[1]

BY O. F. WADSWORTH, M.D.

THE case which I wish to report appears to belong to a class characterized by a very distinctly defined group of symptoms. At intervals varying in length both in the individual cases and the same case, there occurs paralysis of all the branches of one oculo-motor nerve. The duration of the paralysis also varies. Always, it is the same nerve that is affected, the other nerves remaining free. In most cases, possibly in all, the attacks are preceded, or, at least, accompanied by headache, confined to the corresponding side of the head, and chiefly localized in the frontal region.

Pauline and Frances, twins, were born of healthy

[1] Read before the American Ophthalmological Society.

parents, both of whom are still living and well. There were five other children in the family, two older, three younger than the twins. With the exception of a girl, the second after the twins, who died at eleven months of "congestion of the brain," all were healthy. In June, 1874, when the twins were nearly three years old, both had scarlet fever, and both had a discharge from the ear. Both seemed to recover well and to be healthy for some time afterward, although in both a slight discharge from one ear continued, and Pauline had occasional headaches.

Although Frances is not the one whose case I present, it may be of interest to follow briefly her history, as it seems to have a bearing on the etiology of the other case. In September, 1877, when six years old, three years after the attack of scarlet fever, she began to complain of headache. The headache returned more frequently and was of longer duration till the following December, when she had a convulsion. Three weeks later convulsions recurred, and the attacks became more frequent until, finally, they occurred almost daily. About the middle of March, 1878, after a convulsion, she complained that she could not see. A week later, March 21st, she was admitted to the nervous department of the City Hospital. On the same day, I found well-marked optic neuritis and many white spots around the macula in both eyes. May 13th, Dr. J. Orne Green found the left membrana tympani much thickened and drawn in. She remained in hospital eleven weeks. The headaches and convulsions ceased, and the discs became atrophic. Sight did not return. I saw her again February 24, 1879, in the out-patient department. She had had an occasional headache since leaving the Hospital, but was otherwise, excepting her blindness, well, well nourished, of good development, rosy-cheeked. She could only distinguish light from darkness. The pupils were large; the optic discs presented the appearance of atrophy following neuritis. Since that time, I learn that she has been well, free from headache, and has had no discharge from the ear. She is now a pupil at the Perkins Institution for the Blind, in South Boston.

Pauline, the subject of the oculo-motor paralysis, after the scarlatina in the summer of 1874, had attacks of headache every month or two; in the early part of 1878, headache for several hours each day during three weeks. The monthly or bi-monthly headaches continued, and, on February 24, 1879, being then seven years old, she was brought to the hospital, with her sister, having suffered from headache daily for two weeks. The headache was referred to the right supra-orbital region; was said to commence every day about noon, to intermit about three, and to recur about five and then continue some four hours. There was vomiting on the first two days. Appetite impaired; dejections and micturition normal; tongue clean; general appearance good; a slight discharge from right ear; swollen glands behind each ascending ramus of jaw. Dr. Green examined the ears, but my notes state only that he found inspissated pus in the right. The right eye was quite normal, its refraction nearly emmetropic; the left eye highly myopic, with a regular crescent of one-third to one-half the diameter of the disc.

March 29, 1880, she was seen again. Meanwhile, headache every month or two, usually ushered in with vomiting, and lasting one to three days. When free from these attacks, she had appeared perfectly well. She was at this time suffering from headache which had lasted a week, the pain referred, as always, to the right supra-orbital region. There was vomiting at the beginning of the attack. She moaned in her sleep. Tongue clean; dejections regular; pulse 100, temperature 98.8°. Five or six days after this attack began, ptosis and divergence of the right eye was noticed.

There was paralysis of the right motor oculi. In other respects, the condition of the eyes as before. Dr. Green again examined the ears, but my notes only describe the condition he found in the left. Its membrana tympani was much drawn inwards and opaque from swelling, and there were several spots of ecchymosis. Its hearing was very fair.

At the end of February, 1887, Pauline came again to the Hospital. She was now fifteen, well grown, and apparently healthy. Her headaches had diminished in frequency; for the last few years, she had had three or four each year, lasting from one day to two weeks, the more severe ones being accompanied by complete ptosis of the right eye and dilatation of the pupil. She had noticed no diplopia at these times, and no special change in the position of the eyeball. She stated that the ptosis and dilated pupil always continued till the headache was over, and then gradually passed off, so that at the end of a week or ten days they had entirely disappeared. The latter statement was probably incorrect, and I shall refer to it again. She had just recovered from a headache of two weeks' duration, accompanied by vomiting. There was a moderate amount of ptosis of the right eye, and nearly complete paralysis of all the other muscles, external and internal, innervated by the right motor oculi. Moderate divergence. The external rectus and superior oblique acted normally. Fundus of both eyes as before. She was seen again twice, at intervals of two or three days.

March 4th, there was a little more movement of the eye inward, upward, and downward; a little more action of the pupil and of the ciliary muscle. R., V. $= \frac{2}{3}\frac{0}{0}$. L., with -14 D., V. $= \frac{2}{3}\frac{0}{0}$. Field normal. She promised to come again but did not.

April 24th, I visited her at her home. There was still a slight droop of the right upper eyelid, decided impairment of movement of eye upward, moderate impairment of movement downward, and inward. The pupil did not react fully, and power of accommodation was imperfect for her age. She was, however, conscious of no defect of motion in the eye, nor aware that the pupil was affected. This was eight weeks after cessation of the headache, and it is probable, therefore, that previous paralyses had not passed off completely, as she had stated, especially as her father had observed that her eyes usually appeared not quite straight. That she should never have been troubled by diplopia is not surprising in consideration of the great myopia and imperfect vision of the other eye.

I was unable to see the mother, who was away at the time of my visit, but the father was positive that the attacks had diminished in frequency of late years, the last severe one having been in the previous July, an interval of seven months. Another fact of much interest I first learned from him, that with each severe attack, toward the end of the period of headache, there was a free discharge of ill-smelling fluid from the right ear, staining the pillow, and requiring syring-

ing for some days. At my request and representation of the importance of treatment of the ear, she visited Dr. Green on May 6th. He found a large polypus completely filling the right meatus and removed it, but after two or three visits she ceased attendance.

These cases apparently occur but rarely. I have found but fifteen reported,[2] with one exception already collected by Mauthner, although very possibly some publications during the last year have escaped my search. And of these fifteen, several are very meagerly reported, two in such a way that it seems by no means certain that they properly belong to this category. On the other hand, with one exception, reported by Gubler in 1860, (Mauthner has recently published notes of a case seen in von Graefe's Clinic in 1864), the earliest observation published was in 1882, so that it is probable that the number of reported cases will increase considerably in the immediate future.

The sex is not mentioned in one of the doubtful cases; of the remaining fifteen, including mine, four were males, eleven females.

In the two cases I have regarded as doubtful the side is not given; of the other fourteen, in seven the right, in seven the left motor oculi was affected.

The age at which the paralysis first appeared is not given in three cases, including the two doubtful ones; in one it occurred at eleven months, in one at eighteen months; the latest date, with one exception, is fourteen or fifteen years. The exception is a case briefly referred to by Buzzard,[3] a woman of thirty, "subject for years to paroxysms of facial tic, recurring about every fortnight, and concentrated more or less definitely in the ophthalmic division of the fifth nerve." Within the last year or two each attack had been followed by partial paralysis of the oculo-motor, the paralytic condition lasting for a few days. One of the attacks he observed.

The varying length of the intervals between the attacks has already been noticed. In the case just cited it was shortest — two weeks. In von Hasner's case the attacks recurred every month, and although preceding by two years the establishment of the catamenia, after their appearance were coincident with them. In most cases the interval was not a regular one, and lasted from a few months to a year. In Gubler's case there were two intervals of three years, then one of sixteen years before the last attack, which was followed a fortnight after its commencement by death.

The period of headache varied, even in the same patient, in one case from one day to several weeks. And a similar difference appeared in the duration of the paralysis. Although the patients often are said to have stated, as in my case, that the paralysis passed off completely in the intervals, there is, I believe, in no case the definite statement that its entire disappearance was observed by the reporter. On the other hand, in several instances, evident remains of the paralysis were observed to persist between the attacks.

With four exceptions, it is distinctly stated that pain resembling megrim accompanied the attacks. Of the exceptions, Gubler's patient was seen only some days after the paralysis was established; the case is reported very briefly, but it is said that the man had all his life been subject to violent attacks of megrim. Weiss's case is also very briefly reported (the patient was of little intelligence and unfamiliar with the German language); nothing is said of pain. The other two are the cases classed as doubtful. These were reported in a discussion which followed a report of a case by Snell.[4] In one, by Ormerod, it is not clear that there were ever more than two attacks; the patient was an elderly woman; the Argyll Robertson symptom was present, but the knee-jerk not wanting. It is stated that there was pain in the region of the supra-orbital nerve, but nothing to suggest megrim. Of the other, by Beevor, we learn only that he "had seen a similar instance in which exposure to cold winds were (*sic*) assigned as the cause." Perhaps both these cases had better have been omitted from the list.

Only in one case, that of Thomsen, was there observed contraction of the field of vision during the attack, and here the concentric contraction was found in both eyes, although of much less amount in the eye free from paralysis. This case was complicated by epilepsy. The man was thirty-four years old; the recurrent paralysis began at the age of five; the epilepsy first appeared at thirteen years, and followed directly a fall from a ladder which produced temporary unconsciousness.

The course of the disease is extremely variable. In some cases the duration of the paralysis and the intervals between the attacks seem to have continued the same; in some the attacks became more, in others less severe; in some again the periods of freedom became longer, in others shorter. There is no instance of permanent relief, perhaps because the time of observation was not sufficiently prolonged. Three cases terminated in death.

Different interpretations of the cause of the affection have been given. Some have considered it a purely functional disturbance, analogous to ordinary migraine. Others have supposed a tumor or inflammatory process at the nucleus of the nerve. Others again a pachy- or lepto-meningitis, an anomaly of the vessels, or a tumor at the base.

It seems to me very difficult to admit the theory of a purely functional disturbance, especially in view of the partial persistence of the paralysis noted in several cases between the attacks. There are also difficulties in the way of an assumption of a disease-process at the nucleus, lasting for many years, extensive enough to involve all branches of the nerve, subject to frequent exacerbations, and yet never affecting any other nerves, either of the same or opposite side. A basal origin appears more probable.

The results of autopsy in the three fatal cases also point to the base as the seat of the trouble. Gubler's patient died after a short illness with delirium running into coma. A plastic exudation surrounded the right motor oculi. There were other lesions, but this was the one which seemed best to explain the paralysis.

Weiss's patient died of tuberculosis of the lungs. The right motor oculi was flattened, gray, and showed a tubercular enlargement at the point where it issued from the crus cerebri. The granulations did not extend into the brain substance.

Thomsen's case passed from his observation and died about a year later of gangrene of the lungs. The end of the case was reported by Richter. There was a fibro-chondroma of the right motor oculi, which

[2] Since this case was read a case has been reported by Hinde and Mayer in the New York Medical Record, Sept. 24, 1887.

[3] Clinical Lectures on Diseases of the Nervous System, p. 164.

[4] Lancet, I, 938, 1885.

doubled its size, but had developed in such a way as to separate the nerve fibres without destroying them.

In my own case the history points pretty distinctly to a direct connection between the aural disease and the paralysis of the third nerve. There can scarcely be a doubt that a meningitis was set up by the aural disease in the twin sister. It seems here not unreasonable to suppose an exudation or thickening over a limited portion of the dura, which makes pressure on the motor oculi whenever a re-excitation of inflammation in the ear with retention of pus induces an increased vascularity or swelling. And when it is remembered that the third nerve penetrates the dura some little distance farther forward than the fourth and sixth, it is seen that such a limited thickening might readily be situated so as to affect the third nerve alone.

CASES OF BURNS, WITH SPECIAL REFERENCE TO COMPLICATIONS, SEQUELÆ, AND TREATMENT.[1]

BY JAMES E. CLEAVES, M.D., OF MEDFORD.

Bryant's remark, so often quoted in surgical treatises, that "half the cases of burn admitted into a hospital die, and half of those that die do so within the first three days," whether proved to be true or not, certainly carries with it some hint at the gravity of such cases. Of course, in a general practice, one meets with fewer, and, as a rule, with less severe cases than are seen at a hospital. Now and then, cases more or less severe, or characterized by more or less embarrassing complications, come under the care of the general practitioner, and the importance of the subject grows, as the increase in causes brings greater liability to these accidents. Without claiming to bring to your notice anything peculiar in the following cases or methods of treatment, it is the purpose of this paper to refer to cases illustrating, in a small degree, some of the complicating features of severe burns, and to speak briefly of treatment applicable in these and similar cases.

Case I. A feeble lady, aged seventy years, was badly burned about the whole front of the right arm and right breast, from her clothes taking fire. The burn was especially severe near the axilla and over the breast. From her age and general weakness, her system was in such a condition that the shock from this burn of comparatively small size was very severe. When seen first by me, she was in a state of marked prostration, with very feeble pulse, and with alternate attacks of chilliness and fever. The pain of the wound was very great, and, for its relief, morphia was used subcutaneously, while brandy and beef-tea were given as stimulants. Warmth from hot-water bottles and blankets was applied externally until reaction came. This case illustrates the fact evident in all severe cases of burns, that the early treatment must be of a constitutional, rather than of a local nature. The wound itself may be left untreated for the time being, but immediate attention is required in severe cases to allay the patient's pain, and to lessen the violence of the shock. The time of the infliction of a burn is one of the chief periods of danger; according to Heath, fifty per cent. of the fatal cases terminating during the period of shock. Pain is a most constant symptom in burns, unless they be of such a serious character as to blunt the sensitiveness of the patient's nervous system by the violence of the shock of the accident. In the case under consideration, reaction came on at the end of the first day, with moderate fever, the temperature being, part of the time, at 102°. The wound was first treated with carron oil, and later, poultices with carron oil upon them were applied to hasten the sloughing. On the eleventh day, the patient began to complain of chilliness and of pain in the right lung, and to have a slight cough. On examination, the pulse was found to be 120, temperature 103°, and, at the base of the right lung, were the characteristic evidences of pneumonia. The attack developed with little warning, and was of a mild type, although adding to the general prostration occasioned by the discharging wound on the arm and breast. In this case the poultices were made larger, so as to cover the right side of the chest, and stimulants were given freely.

Pneumonia and bronchitis, as well as inflammations of other viscera, are not infrequently complications of severe burns involving the chest or a large part of the body surface. The internal organs have to take upon themselves the work of the destroyed skin as an excreting organ, and also have a larger amount of blood than usual sent to them, so that congestion and inflammation result. These inflammations are usually of a low type, coming with obscure symptoms during the period of inflammation and suppuration in the wound. Erichson, in observations of fatal burns, found the brain affected in thirty-three out of thirty-seven cases, the thoracic viscera in thirty out of forty, and the abdominal viscera in thirty-one out of forty-two cases.

In Case I, after sloughing, there was a large ulcer, which healed by granulation, surgeon's adhesive plaster being used to compress and restrain the granulations.

At present time, four years after the accident, there is persistent neuralgia about the right arm, and the cicatrix at the front of the axilla is much thicker than at other parts of the burned surface, and the arm is considerably restrained in its outward and upward movements. The patient's age, however, renders any surgical operation for restoring motion impracticable.

In similar cases suitable for operations, where bands of cicatricial tissue cause severe deformity, as about the joints or chin or neck, the bands may at times be cut, or plastic operations for replacing the cicatricial tissues by normal tissues from neighboring parts are sometimes called for. An interesting report of such cases was published by Dr. C. B. Porter, in the *Boston Medical and Surgical Journal* in 1878, and, at its close, were given the following suggestions for plastic surgery:

"(1) Dissect out, if possible, all cicatricial tissue. (2) The pedicles should be arranged so as to get the largest supply of arterial blood possible. (3) Flaps thick with adipose tissue do well, and the fat is absorbed, and the flap gradually assumes the character of the surrounding skin. (4) Compression of the parts operated upon prevents a collection of blood underneath, and hastens the union of the flap to the parts beneath."

Case II illustrates in a marked degree a complication which is very common in severe cases of burns; namely, the congestion of the kidneys, as shown by the presence of albumen in the urine. This patient,

[1] Read before the Massachusetts Medical Society, June 7, 1887, and recommended for publication in the Journal.

a man twenty-eight years old, by trade a cloth-printer, was severely scalded by the bursting of a drying can in a bleachery. He was burned about the forehead, on the side of the head and neck, on the back and buttocks, and about the front of the left thigh, and both lower legs and feet. For three weeks, during the height of the inflammation of the burn, there was albumen in the urine, varying in amount with the degree of fever present. In the "International Encyclopædia of Surgery," there is an interesting report of cases at the Pennsylvania Hospital, in 1880, in which cases careful examination of the temperature and urine was made daily. In these examinations it was found that in mild cases, where there was no variation from normal temperature, no albumen was discovered; while in graver cases, with temperature ranging from 101½° upward, albumen was always present in amount corresponding with the elevation of temperature. The same explanation is offered for the congestion and inflammation of the kidneys as in cases of pneumonia or bronchitis following burns or scalds.

In this case, although there were extensive wounds about the head, no delirium or symptoms of congestion about the brain were present at any time.

In CASE III, a man burned at the same time, the burned surface was upon the face and side of the head, covering a space about the size of the hand. On the fourth day a mild delirium began, which continued for ten days. In this case the wound healed badly. There was great prostration, with formation of bed-sores. The treatment of the burned surfaces in these cases did not differ materially from that in Case I — carbolized oil (1 part to 20) and salicylated vaseline (10 gr. to ℥j) being used in place of carron oil.

CASE IV. A boy twelve years old, was burned with strong sulphuric and strong hydrochloric acids. Carron oil was ordered by the physician, who saw the boy at the time of the accident, and this was used at the boy's home for two days before I saw the case. There was very little pain on the day of the accident, and on the second day the boy was dressed and playing with the other children of the family. The burns began to be painful on the night of the second day, and on the third day, when I first saw the case, there was very severe pain and considerable fever. On examination, I found several small burns about the left knee and leg. The right leg was badly burned from the buttock to the foot. The general appearance of the limb was as if the skin had been parboiled. It had a whitish, sodden look and there were no blisters at any part. The boy's temperature had come up gradually to 103°, and the pain was increasing. Opiates and quinine were used, and the carron oil applied to the wound. By the sixth day, the entire injured surface was denuded of skin and left red and raw. The carron oil was so disagreeable that carbolized cosmoline (1 part to 20) spread upon lint was used, and this giving rise to symptoms of carbolic acid poisoning (vomiting, dark stools and dark scanty urine with the odor of carbolic acid), plain cosmoline was used. On the twenty-eighth day, the granulations had become quite prominent and bleeding, and powdered alum was sprinkled over the surface of the wound and strapping applied with cosmoline dressing outside. The wound healed slowly, the surface breaking open several times with a fresh discharge of pus, before healing was effected. While the cicatricial tissue was forming the foot became drawn up until it nearly touched the buttock.

This case illustrated the fact that even in badly contracted limbs much may be accomplished without resorting to surgical operations to overcome the contractions. Mechanical appliances were used in this case, consisting of a splint made of one-fourth inch iron wire, fitted to the patient's back and running parallel to the limbs; so that with surgeon's plaster, extension could be obtained without interfering with the dressings applied to the wounds.

The most troublesome feature of this case (and one which has persisted to some extent to the present time, five years after the accident) was the most provoking itching, sometimes causing the boy to cry for an hour at a time, especially after dressing the leg. Several times morphine was administered to relieve this symptom after dressing the wound. Since the healing of the wound, carbolized cosmoline has been found to give the most relief for this symptom.

CASE V. A very strong, healthy young man, about twenty years old, while playing with a boy, received a handful of unslaked lime in his face. His mouth being open at the time, some of the powdered lime was inhaled.

He called at my office *three hours* after the accident, complaining of burning in the mouth and throat, but saying nothing of any difficulty in breathing, although his voice was husky. The mouth and throat were inflamed and reddened, but there was considerable expectoration. The lips were congested and the face wore an anxious look. *Fourteen hours* after the accident, I saw the patient and found him quite feverish, with quickened pulse and respiration and with labored breathing. He complained most of pain in the mouth, and of a slight pain in the chest. *Twenty-four hours* after the accident, the pulse was 108, temperature 103°, and respiration 40 per minute. Dyspnœa had increased, there was a frequent cough, and muco-purulent expectoration. *Thirty hours* after accident, pulse 130, temperature 104.05°, respiration 48, and labored. Patient was delirious at times, but could be roused to take medicines and nourishment, swallowing with little difficulty. The cough had become almost constant and a large amount of muco-purulent fluid was raised. There were moist râles throughout both lungs. *Three hours* later the delirium was more marked, and the bowels had become quite loose, moving involuntarily.

Forty-one hours after the accident, pulse 120 and feeble, temperature 104°, respiration 62. Mind wandering continually. Face and chest congested. Râles in both lungs.

The patient died forty-eight hours after the accident.

In this case, there was marked congestion and inflammation, produced speedily from an apparently insignificant cause. The location of the lesions was such that a slight burn was followed by complicating inflammation speedily proving fatal. The treatment in this case was, at the first visit, the use of gargles of dilute acid solutions to counteract the lime. At the second visit, stimulants were ordered and used freely until the case terminated, brandy and carbonate of ammonia being chiefly relied upon. External applications were applied about the chest as in cases of acute bronchitis. Moist air was breathed by the patient.

Burns and scalds about the mouth are not infrequent in young children, from drinking boiling water or inhaling steam. Such cases are frequently fatal from the resulting œdema of the larynx and inflammation of the bronchial tubes. In some of these cases, tracheotomy has been performed, but the operation cannot be regarded as very successful. Ashhurst refers to twenty-eight cases of the kind, of which twenty-three terminated fatally.

In summing up, it might be said that the principal points in treatment are: at first, to relieve pain (generally by means of opiates), to lessen and overcome shock by the use of stimulants and heat, and to dress with simple dressings; later, to support the patient's strength during the time of inflammation and suppuration, and to give to complicating inflammations their appropriate treatment; to keep down granulations by strapping or by mild caustics; to help healing, if necessary, by skin-grafting; to overcome contractions by mechanical appliances, or by strapping, if possible; and, to restore deformed parts to as nearly as possible normal conditions, by surgical means if necessary.

REPORT ON PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M.D., AND R. M. LOVETT, M.D.

OPEN INCISION IN CLUB-FOOT.

Phillipson [1] considers that congenital club-feet may be grouped in different classes according to their severity, but in all classes the chief hinderance to permanent correction is in shortened soft tissues, tendons, fasciæ, ligaments. Schede has in several cases adopted and developed Phelps's method of direct incision in severe cases. In light cases, Phillipson advises simply subcutaneous tenotomy of the tendo-Achillis, plantar fuscia and that of the internal lateral ligament below the internal malleolus, and the tendon of tibialis posticus. In more severe cases, the flexor longus digitorum, abductor, hallucis and flexor hallucis longus, and flexor brevis need also to be divided. If the head of the astragalus is very much distorted a linear division can be performed, but not a wedge-shaped excision.

The incision through the skin for these divisions should be on the inner side of the foot, and the tibialis tendon can be carefully freed and the artery and nerve spared. The wound should be dressed antiseptically, and the foot corrected and done up in an immovable plaster silicate bandage for four weeks, and later in a removable silicate bandage.

TREATMENT OF CLUB-FOOT.

Lorenz [2] thinks that club-foot can be treated without section of the bone, provided proper treatment is commenced at proper time and carried out for a sufficient length of time.

Treatment should begin immediately after birth and tenotomy of the tendo-Achillis should be done at first, and manual correction should be begun immediately. The foot can best be held in a plaster-of-Paris bandage, which should be changed every fourteen days. In lighter cases correction by sticking-plaster strips can be used. After a while, as soon as the foot is corrected and the child able to walk, a properly constructed shoe.

If operation on the bone is necessary, open incision of the soft parts, or tenotomy of the ligaments are not to be relied on, as based on imperfect pathology. Wedge-shaped resection of bone or enucleation is preferable.

INTERMITTENT HYDRARTHROS GENU.

Nicolaysen [3] reports a case in a soldier who was attacked by an effusion in the knee which ran the usual course, but reappeared once after over-exertion. Six months later the same trouble appeared, and lasted two or three days, disappeared spontaneously to present itself regularly after an interval of fourteen days, during which time the joint was entirely well.

Treatment appeared to be without avail until arsenic had been used for two months, when recovery took place.

The spleen was found enlarged when the arsenic treatment was first begun, but gradually diminished. The patient came from a place where intermittent fever prevailed.

INTERMITTENT LIMPING.

Terrillon [4] describes a case of an affection not infrequent among horses, but rare in human subjects. In veterinary practice it is not uncommon for horses to be found that are apparently perfectly sound when at rest and at the beginning of motion, but that begin to limp (generally in the hind leg) as soon as active motion is carried on; with evident pain and discomfort, which increases until the animal is covered with perspiration and falls. Recovery takes place after prolonged rest, but symptoms recur and eventually the animal is killed as useless. At autopsy, a thrombus of the iliac is found.

Terrillon's case in a human subject was that of a man twenty-seven years old, a drinker, who complained of pain in the left foot, which intermitted, but reappeared suddenly on motion, with so great severity that after a while the patient was unable to go more than a few steps. Gangrene of the foot followed, and amputation with recovery.

JOINT AFFECTION IN TABES DORSALIS.

A most complete investigation on this subject has recently appeared,[5] based on the investigation in the Tübingen Clinic, and on 107 cases collected in the literature of the subject. The following is the order of frequency in which the joints are affected: knee, 78; hip, 31; shoulder, 21; tarsus, 13; elbow, 10; ankle, 9; wrist and jaw, each 2; spine, 1. The symptoms usually appear suddenly, without known cause, and often without pain. The joint affection appears usually in an early stage of the disease. The swelling of the joints may be quite large and consist of an effusion in the joint and an œdema of the whole limb. This often appears suddenly and may subside in part with equal rapidity. There are, of course, severe and milder types. In the severe cases the synovial membrane is pale and covered with granulations, the capsule is thickened and covered with a deposit of lime, and in the severest, the capsule entirely disappeared, and the ends of the bone become distorted, hypertro-

Also, Rotter. Centralblatt f. Chirurgie, No. 22, 1887, p. 415.

phied or atrophied. The effusion is rarely purulent, and if so, as a rule it is due to violence. Luxation and spontaneous fracture may occur. Syphilis was found in 13 of the 109 cases, in 21 was known positively not to exist, in 5 it was doubtful, in the remainder no facts could be determined.

Sonnenburg[6] has examined a large number of preparations of arthropathia tabidorum. He considers, with Virchow, that the tabes dorsalis and the lesion of the nervous centres present a predisposing cause or a predisposition through the faulty nutrition of the bones. The matter is, however, as yet not determined, as in some cases it would appear that lesion of the joint was the origin of the lesion of the cord.

Rotter[7] has excised four times in such cases, and reports a fair result in two cases. From what he has found he is inclined to regard the affection as one of fracture of the joint or primary traumatic arthritis, not recognized owing to the impairment of sensation.

Krauss[8] mentions a man who underwent amputation of the thigh for deformity of the knee; neuralgia of the stump followed, and later section of the sciatic was done. The subsequent course and autopsy proved the disease to have been tabes dorsalis, though neither the appearance of the knee nor the clinical course gave any evidence of a central spinal arthropathy.

KNOCK-KNEE.

Mr. Rushton Parker[9] speaks of the tendency that slight degrees of knock-knees show toward recovery if the body weight be taken off the leg even for a short while. He would advocate this as the first and mildest means of treatment in beginning cases, simply that the erect position should be avoided for awhile and the child should creep. Next flat-foot is so commonly associated with knock-knee, and withal so much more common than knock-knee, that it seems reasonable to attribute the knee deformity to it, and the supposition is verified, Parker says, by the success of the following method of treatment: the simple device of raising the inner side of the boot sole and heel and sloping it off toward the outer side, a contrivance adopted from Mr. Thomas.

If mechanical treatment is made necessary, he finds Thomas's knee and splint of the calliper variety the most useful, and there are few cases, he asserts, where the deformity cannot be so corrected without laying up, unless the bend is excessive.

In very hard cases he at once uses osteotomy and applies a long Thomas knee-splint and treats the case as he would treat an ordinary fracture of the leg.

RICHETS.

Dr. Whitman[10] has investigated the question whether children are apt to out-grow bow-legs and knock-knee, by a series of observations made on adults in the streets of Boston. Of 2,000 adult males counted as they were met in the street, it was found that 20% showed some degree of bow-legs, but knock-knee in all other series of observations only appeared in 1.6%. From a consideration of the attainable statistics on the prevalance of bow-legs in children, Whitman concludes that the proportion is about the same as in adults, and reaches the following conclusions: "(1) A bow-legged boy is more likely to become a bow-legged man than a boy with straight legs. (2) If such a proportion of bow-legs exists among adults as would appear from these observations, it would seem more reasonable to treat such cases in childhood rather than to trust to nature for their rectification. (3) If such deformities are to be treated, the sooner treatment is applied the better."

LATERAL CURVATURE.

Mr. Barwell[11] calls attention to the fact that lateral curvature seems to be very much on the increase, a fact which he attributes to the greater pressure of school work. He takes occasion to assert again his original belief that asymmetrical muscular action is at the root of the trouble. Predominance of the muscles on one side, resulting from postural or respiratory causes, causes a lateral curvature of the spine, at first wholly to be corrected by proper apparatus. From this condition there result in the process of growth, the well-known bony and ligamentous deformities. The primarily lumbar form he finds oftenest due to pelvic obliquity from a short leg, and in dorsal cases in girls he holds accountable the faulty position assumed in writing at a desk or table.

OSTEOTOMY, OSTEOCLASIS AND FORCIBLE STRAIGHTENING.

Margary[12] has performed 361 osteotomies, 10 cases of osteoclasis, and 26 of forcible straightening. 207 of the osteotomies were for genu valgum, 83 genu varum, 18 for contraction at the knee, 7 for deforming callus, 4 for anchylosis after polyarthritis, 4 for rachitic curvature of the upper extremity, 1 for luxation of the elbow backwards. 3 patients died, (but none of sepsis). In 1, amputation was necessary. Suppuration was rare. In 1 case, anchylosis of the knee followed. Resulting impairment of motion was very rare. The average duration of treatment was from 2 to 2½ months.

THE AORTA IN POTT'S DISEASE.

Lannelongue[13] has found that there is always a side displacement of the aorta as well as a forward curvature in severe cases of Pott's disease; the aorta was found at autopsy to be firmly adherent either with the walls of a prevertebral abscess or with inflammatory tissue.

An abdominal aortic murmur can in some cases be heard in the region of the navel. The heart is frequently dilated and hypertrophied.

SILICATE JACKETS.

Dr. Burns,[14] of Russia, objects to Sayre's plaster jacket on the ground that it cannot be removed at will for purposes of cleanliness, or for gymnastics in cases of lateral curvature. As a matter of fact, the jacket as now used by Dr. Sayre, is split down the front and laced, so that it can be removed easily at any time, yet the suggestion of Dr. Burns is of interest. He uses four pounds of the best plaster-of-Paris mixed with twenty pounds of the ordinary grade, and three or four pounds of water-glass. Linen bandages are used, the jacket is moulded over a plaster jacket, which has been prepared as a mould and then cut down the front and provided with leather straps and

buckles. It is described as light, cleanly, and durable. The expense is an objection to its use, as each jacket costs between two and three dollars.

POTT'S DISEASE.

Dr. Whitehead[15] describes a method of making continuous extension with a plaster jacket, which he advocates very strongly, and he relates the history of several illustrative cases.

A swathe of adhesive plaster is put around the patient's chest before the jacket is applied. To this are applied two stout webbing loops running from front to back over each shoulder. Two stout steel springs are imbedded in the jacket, and are held in place below by squares of perforated tin, which are firmly incorporated in the waist of the jacket, while above they carry a buckle and overhang each shoulder. The shoulder loop of the adhesive-plaster swathe is attached to the springs, the buckles tightened, and a very efficient extension and counter-extension must necessarily be obtained. It must, however, be a very stout skin that would not grow sore under the adhesive plaster applied under such conditions.

Attention ought to be called to the article of Dr. Ridlon,[16] in which he relates two cases of Pott's disease, one cervical and the other upper dorsal, and calls attention to the difficulty of making the diagnosis between the two conditions in very young children.

LOCAL INJECTIONS IN TUBERCULOUS JOINT DISEASE.

Kolischer[17] was led to the method which he describes by observation of the processes of spontaneous cure in tuberculous joint disease, by calcification and by inflammation excited by traumatism. Both these processes are excited by the injection of a concentrated solution of calcium phosphate at the seat of the disease. The solution is made as follows: seventy-five grains of neutral phosphate of calcium are dissolved in twelve ounces of water, and phosphoric acid is added until perfect solution is obtained. Then nine minims of dilute phosphoric acid (Austrian pharm.) are added, with three ounces more of water. The whole solution is sterilized by boiling and injected into the fungus mass by means of a syringe with a platinum needle. The joint is dressed with gauze impregnated with a solution like the above, except that about ninety minims more of dilute phosphoric acid should be added to it. The pain which follows the injection is very severe, and it is generally necessary to use morphine. There is much fever often, and sometimes a good deal of induration about the joint is present, but it disappears. The skin breaks in many successful cases, but the dressing is continued and a calcification and cicatrization go on. Very favorable results are claimed for the treatment by Kolischer and Del Torre.[18]

PSOAS ABSCESS.

The treatment of psoas abscess is discussed by Owen.[19] Spontaneous absorption is out of the question, and he prefers incision to waiting for the abscess to burst. He favors the anterior opening in the groin, with a counter-incision in the back, except in small abscesses where he would make one small opening in the loin. He uses warm iodine water for washing out the cavity. If the temperature remains high after operation it is likely that another abscess has formed on the opposite side of the spine, which must generally be opened independently, although where a bilateral abscess exists there is generally intercommunication between the two collections of pus.

KNEE-JOINT DISEASE AND EXCISION.

The large number of articles written by eminent men within the last six months, on the excision of the knee, shows an increasing interest in the operation on behalf of both general surgeons and orthopedists. Especially do these articles deal with methods of fixation after operation.

Mitchell Banks[20] furnishes, perhaps, the most complete article of all. He speaks of the increasing popularity of the operation and gives briefly its history in England. In private practice the operation is rarely necessary, and in hospital patients he is much influenced by the stage of the disease and the circumstances of the patient. In patients less than fifteen years old, he believes that the disease is almost always amenable to mechanical treatment. But in patients from fifteen to twenty-five, the disease is much more unmanageable, while in older people it is more formidable still. After trying all the incisions he has settled upon the one below the patella, and he does not use the Esmarch bandage or tourniquet during the operation.

He dovetails the femur into the tibia by cutting a concavity in the tibia with a butcher's saw, and cutting the femur to fit it. The posterior crucial ligament generally is sound, and if it can be saved it gives much stability to the joint. As to the removal of diseased tissue he says: "It is hardly possible to remove too much, for after all, the only thing that is wanted is a skin covering for the bones." In the matter of a splint, Mr. Banks' preference is for a common Thomas knee-splint, but he has no doubt that some of the other methods are equally efficient.

Gerster,[21] perhaps, will serve as an exponent of American ideas in the matter of excision of the knee. He agrees that it is to be especially avoided in infants, while for adults he advises the operation. For complete excision he uses Hahn's incision above the patella, as it gives better access to the bursa under the quadriceps. Much care is needed in sawing off the ends of the bones; in the femur section should be made in a place corresponding to the transverse diameter of the epiphysis, and in the tibia at a right to the long axis of the bone. The bones are secured in place by four long steel nails, which are crossed and hold the bones firmly. Outside of the antiseptic dressing pasteboard splints are used in children, and plaster-of-Paris in adults. For thirty days the dressings are let alone in favorable cases, and then the nails, tube, and dressing are removed and a silicate splint applied. Of twelve cases operated on by him (adults and children), ten were cured, one died of tuberculous meningitis, and one had such severe suppuration that the thigh had to be amputated.

Stoker,[22] writing on the same subject, insists upon the necessity of observing three points: (1) Complete removal of all diseased structures; (2) relative permanence of dressings; (3) thorough fixation of parts.

He finds it possible to keep on dressings two or

three weeks, and often finds the wound healed at the end of that time; he is able to keep on dressings longer, since he discarded the use of the tourniquet and Esmarch bandage, for the after-oozing is avoided. Outside of the dressing he applies hoop-iron splints, bent to fit the contour of the leg, except at the knee, where they are bridged. Plaster-of-Paris he has discarded, on the grounds that it is dirty, that it loosens so easily, and that its removal causes so much pain to the patient. The bones are held together by two silver dowels, which are introduced into the tibia, one on each side of the tubercle, awl-holes having been bored, and driven up into the femur, but they are not crossed. Mr. Baker[23] uses much the same method for fixation, except that he drives in steel pins with an awl-handle and leaves them in place by removing the handle, but he crosses them, to which Mr. Stoker objects, on the ground that greater precision is obtained by not doing so. The bone pins advocated by Marsh, are objected to on the ground that they injure the cancellous tissue very much and break easily.

The technique of the operation is also discussed by Howard Marsh,[24] who has been annoyed in former years, after operation, by the riding up of the femur while the tibia lay still. This formed a serious addition to the inevitable displacements produced by moving the limb and by the involuntary muscular jerks. The apparatus described by Mr. Gaut, is the one upon which he has finally settled; it consists of an outside and a posterior splint. The latter runs the whole length of the leg, and is carefully padded and applied so as to raise the tibia to the level of the femur. This does away with the need of binding down the femur so tightly as is ordinarily done. Then the bones are pinned together with bone knitting-needles, which are driven into the tibia and femur through holes made by a brad-awl. An outside splint running the length of the leg, but interrupted at the knee, is applied along the outside of the leg, terminating below in a foot piece. All this is done before the dressings are applied; suturing and dressing are then done. The bone pins are cut off and left in place.

Riedinger[25] proposes to saw off the under surface of the patella and also of the front surface of the sound part of the femur and tibia after excision of the diseased portion and securing the femur patella and tibia together. This has also been done by Neuber. Riedinger has made a longitudinal straight incision directly over the middle of the joint, sawn the patella into two lateral halves, separating the ligamentum patellæ in the middle; the ends of the femur and the tibia after division of the crucial ligamentum patella are brought out between the split patella and sawn off in the ordinary way.

Israel[26] employs a convex curved incision which extends to the lower border of the tuberosity of the tibia which is sawn off obliquely, saving in this way the insertion of the ligamentum patellæ. After the operation the tuberosity of the tibia is nailed on to the tibia. Israel endeavors by passive motion and massage and articulated splints to secure some motion.

Tiling[27] separates the tuberosity with a chisel, thus sparing the ligamentum patellæ; the other ligaments are also spared by chiselling off the different bony insertions when sound.

HIP-JOINT DISEASE.

In his new book "Hip Diseases in Childhood," Mr. Wright[28] stands forth as the champion of the operative treatment. He speaks from large experience, and the book is most carefully and distinctly written. The account of the pathology of the disease is probably the best in the English language, the conclusion is very brief: "In the vast majority — almost the whole — of the cases of 'morbus coxæ' the disease begins as an osteomyelitis of the upper epiphysis of the femur, or of the intermediate neighborhood of the epiphyseal line.

The symptomatology is full and complete. He attaches less importance to muscular rigidity and more to thickening of the trochanter than American authors do, and he adopts the classification into stages proposed by Mr. Adams. Two-thirds of the book is taken up by the discussion of treatment or rather excision, for the two are almost synonymous in Mr. Wright's mind. A quotation will best show his view of the matter. "Treatment, short of excision, when once suppuration occurs, is useful only as a palliative, or a means of temporizing. He gives a table of 2461 cases of excision of the hip which shows 1566 recoveries to 841 deaths. Two other conclusions of Mr. Wright's would be disputed by American authors, that "A case of hip disease seen before suppuration has occurred, is best treated by the use of a Thomas splint with or without previous extension," and that "excision of the hip cuts short the disease, relieves pain and gives a better limb than the average result obtained without operation." Then follows a table of the author's own excisions, one hundred in number, of which 15 died and 85 recovered.

Clinical Memorandum.

HYDRONEPHROSIS SUPPOSED TO BE OVARIAN TUMOR.

BY S. H. WEEKS, M.D.,
Professor of Surgery in the Medical School of Maine.

BELIEVING, as I do, that this case will be of some interest to the profession, I have prepared the following report for publication. I am indebted to Dr. Alfred Ring, Surgical House Pupil at the Maine General Hospital, for a copy of the Hospital records.

Mrs. M., admitted to the Hospital November 6, 1884. Age, thirty; married; residence, New Hampshire; nativity, Vermont. Has had three children; youngest seven years old. Labor easy, and she got up from each confinement in good condition. Menstruation has usually been regular in time and amount; at times, would extend over several days, and, at such times, be excessive. Patient has been a hard-working woman; appetite fair, bowels regular, weight 138½ pounds. History: In April, 1880, first noticed a bunch about the size of an egg in the right ovarian region. The pain through this mass was sharp and lancinating. During this time, the patient had lung fever, followed by rheumatism in her lower extremities. The growth of the mass, at first, was gradual; but, during the past year, it has been rapid, and the tumor has greatly interfered with respiration, though, at date, the difficulty in respiration is less than it was; the tumor also presses on the liver, though the size of the tumor is less than formerly. Patient states that the size has varied; that when she would pass much water, that there would be a diminution, and when little urine was passed, that the size of the tumor would increase. As soon as she entered the Hospital, she was ordered pulv. effervescens comp., No. 1, every morning; also pil. quin. sulph. gr 2., after each meal.

November 8th. Examination made by the surgical staff; patient first on back, and then in Sims's position. Fluctuation distinctly detected; uterus in normal position, and of normal depth. The diagnosis was ovarian tumor, and an operation for its removal was advised. Examination of the urine showed: color, light straw; odor, normal; specific gravity, 1007; albumen present. She was ordered fifteen grains of bromide of potassium each night at bed-time.

November 10th. Enema given in the morning. At 11 A.M. the patient was etherized, and, in the presence of the surgical staff, and a part of the medical staff, the operation for the removal of the supposed ovarian tumor was commenced. I made the incision in the median line in the usual way, and, on opening into the abdominal cavity, the mesentery was first brought into view, then the bowels and the tumor, covered in front by the peritoneum. Instead of finding an ovarian tumor with a pedicle, I found a cystic kidney. The contents were drawn off by the trocar, which presented a limpid, yellow, and opalescent appearance. About two-thirds of the cyst was removed by the scissors, all hæmorrhage controlled, and the cyst-wall was stitched with silk to the edges of the incision (upper part). The adhesions of the tumor to adjacent structures prevented the entire removal of the cyst. The abdominal wound was closed with four silver sutures. Two rubber drainage-tubes were introduced into the cavity of the remaining cyst, the abdominal cavity being thoroughly shut off from the cavity of the cyst. During the operation the pulse became weak, and f 3i of brandy was given hypodermically. Time of the operation, one hour and ten minutes; weight of tumor, seven pounds.

Recovered well from the ether. No spray was used, but strict antiseptic precautions were observed throughout. 12.30 P.M. f 3i of brandy was given by hypodermic injection. At 12.55, a tablet, ¼ morphia, and $\frac{1}{150}$ atropia, was injected beneath the skin. Pulse 108, temperature 98⅗°, respiration 24. Brandy, f 3i hypodermically. 5.45 P.M. ¼ gr. morphia, to be repeated every four hours until otherwise ordered. 8 P.M. Urine drawn (as also for the few succeeding days); small amount, some sediment. Pulse 116, temperature 90.8°, respiration 26.

November 11th. 2 A.M. Slight attack of vomiting. Slept some during the night. 7.30 A.M. Pulse 120, temperature 100.4°, respiration 22. Very comfortable. 9 A.M. Detected some oozing from wound. The wound was examined, and a small bloodvessel was found in upper part of wound, from which the blood came. This was readily secured by catgut ligature. The antiseptic gauze was reapplied. Patient began to take lime-water and milk — two tablespoonfuls of milk, and one of lime-water every two hours. 5.45 P.M. Pulse 128, temperature 102.2°; brandy f 3iii during the afternoon.

November 12th. 9.30 A.M. Pulse 106, temperature 100.8°, respiration 20. Slept fairly well during night. Wound ordered dressed three times daily, as there was considerable discharge of a sero-purulent character. Milk and lime-water to be increased. 5.25 P.M. Pulse 122, temperature 102.2°.

November 13th. 8 A.M. Pulse 108, temperature 101°. Slept some during the night; is in good spirits. Wound dressed, and looking well. Since noon, beef-tea has been given alternately with the milk and lime-water. During the day, gas passed the bowels. 9 P.M. Pulse 122, temperature 101.8°. Able to take some lemonade, which she found very grateful.

November 14th. 8 A. M. Pulse 103, temperature 100°. Rested well during the night. The discharge from the wound slightly bloody. 7.10 P. M. Pulse 108, temperature 102.4°

November 15th. 8 A. M. Pulse 101, temperature 100°. 7 P. M. Pulse 112, temperature 102.8°.

November 16th. 8 A. M. Pulse 98, temperature 100.2°. 7.30 P. M. Pulse 102, temperature 102°. Very comfortable day. Morphia reduced to ½ gr., still continued every four hours.

November 17th. Morning: Pulse 100, temperature 100.8°. Evening: pulse 104, temperature 102°. The silver sutures were removed. Wound discharging freely. At night, ten grains quinine given per rectum, which caused a slight movement from the bowels, which somewhat fatigued the patient. Brandy f ℥ss given by the mouth.

November 18th. A.M. Pulse 94, temperature 100.2°. Quinine, gr. x, per rectum, causing a slight movement from the bowels. Pulv. eff. co., No. 1, given at night.

November 19th. A. M. Pulse 100, temperature 100.2°. P. M. Pulse 92, temperature 101°. Enema given in the morning, followed by slight movement. Wound discharging freely. Syringed wound with bichloride solution, 1 to 2500. Amount of morphine given every four hours reduced from ⅛ to ¼ gr. Took solid food (steak, etc.) for the first time since the operation.

November 20th. A. M. Pulse 100, temperature 100°. P. M. Pulse 104, temperature 100.2°. Patient bright, and taking more nourishment. Four silk sutures removed from cyst-wall, ordered wound dressed four times daily, and pil. quin., gr. ii, after each meal. Slight attack of vomiting at night.

November 21st. Slept well during the night. A. M. Pulse 96, temperature 99.8°. P. M. Pulse 108, temperature 100.8°. Ordered beef-tea, one-half cup given per rectum every four hours; also quinine, gr. iii, with each injection. Quinine pill by mouth discontinued. Slight attack of vomiting at night. Pulv. eff. co., No. 1, at bed-time, resulting in movement at 3 A. M.

November 22d. Some vomiting in the night. A. M. Pulse 95, temperature 99.2°. Champagne f ℥i given at intervals during the day. Beef enema given every four hours for the day.

November 23d. A. M. Pulse 83, temperature 99.6°. Carbolic acid gauze used on wound. Two beef-tea enemata given in the day. P. M. Pulse 86, temperature 100.6°.

November 24th. A. M. Pulse 90, temperature 99.4°. P. M. Pulse 84, temperature 100.8° Patient feeling very well.

November 25th. A. M. Pulse 79, temperature 99.4°. Enema given in the morning, followed by movement. Bowels slightly distended with gas. Pulv. eff. co., No. 1, given at night, but not retained by the stomach. Quinine, gr. ii, now given every four hours. Morphine, gr. ¼, every four hours.

November 26th. A. M. Pulse 88, temperature 100°. enema given, patient feeling nicely. P. M. Pulse 88, temperature 100.2°. At night had chill, which lasted about half an hour; hot bags and extra blankets applied. Pulse 116, temperature 100°. Quinine, gr. vi, given, and champagne. 10.40 P. M. Pulse 81, temperature 100°. Feeling much better.

November 27th. Patient ate hearty Thanksgiving dinner. Sleeps well nights. The wound is discharging a fair amount, and is dressed four times daily.

November 30th. Wound now dressed three times daily.

December 2d. Slight accumulation of pus at lower angle of wound, where the lowest silver suture passed through abdominal wall.

December 6th. Since last date, the pulse has not exceeded 92; this A. M. it was 104. Temperature not higher than 100.2°; this A. M., 100°. Pus accumulated again in the lower angle of wound. Poultice applied. In other respects, patient doing well.

December 14th. Exuberant granulations about the edge of the wound. Touched with nitrate of silver.

December 16th. Granulations not as prominent. There has been an increase in the discharge since the caustic was applied.

December 18th. Patient up and on the lounge for the first time.

December 25th. Has been up each day since last date. To-day, was able to walk out to the nurses' room.

December 26th. Nitrate of silver again applied to exuberant granulations.

January 5, 1885. Since last date patient doing well. Wound dressed three times each day; discharge small; drainage-tube still kept in. Menstruation began.

January 7th, 10th, 16th, 20th. Patient able to walk a little each day.

January 20th. Patient removed from private room to the ward. Wound now dressed morning and night. The discharge is small. Appetite still continues good. Is gaining in strength. Bowels are regular.

January 21st. Nitrate of silver again applied to exuberant granulations.

January 31st. Since last date, patient's general condition continues to improve. The wound remains about the same, though the discharge is slightly less. The edges of the wound about the drainage-tube have healed.

February 1, 1885. Patient discharged, her general health all the time improving. The wound still discharges, the discharge being thin and watery, but no odor of urine, although I am confident a large part of the discharge is secreted from the walls of the remaining portions of the cyst, in which there seemed to be portions of the cortical structure of the kidney.

The question would naturally arise: why was not a correct diagnosis made before the nature of the tumor was revealed by the operation? It is a fair question, and should receive an answer. The early history of the case tended to mislead the surgeons. I am satisfied that the organ was a "floating kidney" before it became the seat of hydronephrosis, and that this displacement led to obstruction of the ureter, thus causing a dilatation of the pelvis and calices of the kidney by urine, and atrophy of the renal substance, followed by expansion of the capsule, and of what remained of the cortical and medullary substance of the organ.

It will be noticed that the history of the case showed that four years before the operation, she noticed a bunch about as large as an egg in the right ovarian region. In this respect, it strongly resembled an ovarian tumor. In fact, one of our hospital staff, a very skilful diagnostician, saw the patient in the early history of the growth, and, finding this mass in the right ovarian region, pronounced it ovarian tumor. In my experience, it is something entirely new to find a cystic

kidney in such a position. At the time of the examination, with such a history before us, and finding the whole abdominal cavity filled with a cystic tumor, resembling in every particular an ovarian cyst, I feel sure that such a mistake in diagnosis could not have been avoided. I am free to confess that, when I had finished my examination, I felt morally certain that the tumor was ovarian. The appearance of the cyst at the time of the operation may be of some interest: The anterior part of the cyst-wall was as thin as that of an ovarian cyst. As I approached nearer to the base of the tumor, the cyst-walls were thicker, and, at some points, there seemed to be cortical structure of the kidneys very much expanded. The pyramids seemed to be entirely wasted, and the calices were converted into huge spaces or sacs. The patient has been heard from several times since she left the Hospital, and her reports show that her general health has been excellent, being able to do hard manual labor. The last report, about a year ago, stated that there was then a small, fistulous opening, with some discharge, but not enough to cause much inconvenience.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

OCTOBER 24, 1887. The President, DR. O. F. WADSWORTH, in the chair.

DR. ABNER POST showed two cases of

REMOVAL OF THE SHAFT OF THE TIBIA. REPRODUCTION OF BONE FROM THE TIBIA.

The first case was a boy, injured by a blow from a sled, about Christmas. An abscess had formed and had dissected away the soft periosteum from the bone. This was opened in December. The shaft of the tibia became necrosed as a result of the abscess. On the 28th of May all of the shaft of the bone was removed leaving the periosteum. The ends of the channel thus formed were scraped, and the knee-joint was perforated. Bleeding was startling, the blood oozing from every part of the wound. This was controlled by elevation of the part, but it left the patient in a precarious condition. He rallied, however, and the leg which was then limp is now stiff from reproduced bone.

The other case is a girl, upon whom the same operation was done, July 28th. Her leg was kept stiff by means of plaster-of-Paris, and has healed faster, the condition being now the same as that of the boy. She had had rheumatism, but the cause of bone destruction was not so evident in her case as in the other.

DR. W. C. B. FIFIELD said that he was pleased to see these cases. The history of the operation is interesting. It was first done by Géraldis in 1861, and was repeated by him up to the time of his death. The disease seems to have been a phlegmonous periostitis. In the case of a child, whose broken tibia had united at an angle, the French surgeon sawed out a wedge-shaped piece, first carefully removing the periosteum, in hopes of getting new bone growth. The case failed with a false joint, and the good sense of Géraldis then pointed out the difference in prognosis, accordingly as phlegmonous inflammation has or has not preceded the operation. If it has, the periosteum is separated or may easily be separated; if not, separation is a work of difficulty and proliferation is less likely to occur. Even if the normal periosteum can be peeled away, it carries with it no granulations for starting points of the new bone. Dr. Fifield had himself done the operation ten years ago or more, in spite of the unfavorable prognosis of those who were conversant with the case. The shaft being still firmly attached to the epiphysis at the upper end of the bone, it was removed by means of a chain saw. This operation was successful, and the speaker had had the pleasure of seeing his patient skating a year later. After that, he had removed the shaft of the femur on both sides from another child. Bleeding was not profuse in his cases.

The whole shaft of the humerus has likewise been removed. In the after-treatment, the necessity of good feeding was emphasized by Géraldis.

DR. J. C. WARREN said that he had never seen a tibia that needed this operation. Although such cases occur, the occasion must be rare. The tibia is an especially favorable bone for reproduction, owing to the plexuses of vessels in its lower part. In a case of the speaker's, the shaft of the humerus had been pulled off, previous to amputating the arm, leaving the epiphysis and periosteum. Reproduction had taken place to such an extent, that there had been no more than enough flap to cover it, the amputation having removed the lower half of the arm. Such entire removal of bone must be rare in the United States.

DR. ABNER POST, read a paper entitled,

SOME OF THE LATE MANIFESTATIONS OF HEREDITARY SYPHILIS ILLUSTRATED BY CASES.[1]

DR. F. B. GREENOUGH said that treatment is very important in these cases, and that, therefore, diagnosis is very important. Doubtless multitudes of cases of late hereditary syphilis are considered to be scrofula, and are treated with cod-liver oil. He was glad to hear mercury mentioned, for he believed it to be the important drug when it can be borne. Probably if cases of late hereditary syphilis could have been observed early, they would have for the most part presented evidence of the disease early.

DR. J. C. WHITE said that he wished that he felt a greater ability to distinguish between doubtful syphilis and scrofula.

In two or three points he should differ from the reader. He did not find dactylitis common in cases of syphilis; neither is syphilis common with dactylitis, at least three-quarters of the cases of dactylitis seen by him being non-syphilitic. Again we do not know how to distinguish between syphilitic and non-syphilitic dactylitis. Under these circumstances he placed no great stress on the presence of dactylitis alone as proving the existence of syphilis.

Hutchinson's teeth, again, are not a positive proof. When found, they are commonly on the person of a syphilitic, but this, although true as a rule, is not a rule without exception. He has seen them in children where there was no syphilis in three generations.

Further, it is not safe to attach too much importance to the effect of remedies as confirming a diagnosis. He had no doubt but that syphilis is a bacillus disease. Mercury and iodine are both of them pow-

[1] See page 493 of this number of the Journal.

erful destroyers of bacilli, and may be of service in the treatment of other bacillus diseases than syphilis. Mercury is very powerful in destroying lupus when locally applied. He should, therefore, not consider a recovery, while using mercury, as a proof that the disease in a given case was not tubercular.

DR. EDWARD WIGGLESWORTH remarked that in 1871 he had been called in consultation, by Dr. C. F. Folsom, to a somewhat doubtful case of dactylitis syphilitica, published in the *American Journal of Syphilography and Dermatology* for that year, and recently in "Wood's Reference Handbook of Medicine." The diagnosis, subsequently verified, was partly based upon the fact that the swelling of the phalanx was symmetrical, entirely on the dorsal surface and sides, and affecting the distal rather than the proximal end of the phalanx. In strumous dactylitis he held that more commonly, though not always, the proximal end of the phalanx, and even the joint were apt to be involved, the distending deposit shading off as the distal extremity was approached. Taylor, in his treatise upon the "Syphilitic Lesions of the Osseous System in Infants and Young Children," refers to the usual uniform enlargement of the whole bone in syphilitic infants, whereas in cases of osseous inflammation, due to the cachexia of scrofula, the lesions may begin and be greatest at the proximal end of the bone. As to such cases as those recorded by Dr. Post in his very interesting paper, the question is not so much whether the disease is inherited or acquired, or of early or late manifestation, or if there have been observed previous early symptoms or not. The point is whether the malady is syphilis or is not syphilis. Syphilis is syphilis wherever or whenever found, and always calls for its special and appropriate treatment. Cod-liver oil, already referred to, is, however, a tonic often most advantageously employed even in cases of syphilis. Its action has even been compared to that of potassic iodide.

It by no means follows that the date of appearance of syphilitic symptoms is necessarily an early one in cases of hereditary syphilis. Bulkley, Fournier and Zambaco report cases where the manifestations were at the ages of from twenty-three to twenty-six years.

Nor is the disease necessarily hereditary even when the specific symptoms appear at an abnormally early age. Within the year, Dr. Wigglesworth had treated the case of a boy of about twelve years of age, with well-marked secondary symptoms, and the initial lesion upon the penis still evident. The child had been toyed with by an infected nympho-maniac, herself youthful, and had acquired the disease in the usual manner and in the usual situation.

The PRESIDENT said that there are all grades from normal teeth to the perfect Hutchinson's tooth, and that while he had certainly seen such teeth in non-syphilitic people, he had never seen them well marked under such circumstances.

DR. POST, in closing the discussion, said that he was glad that he had brought forward these cases. He had been in doubt as to what to call the series; late hereditary disease is as indefinite a term as tertiary, but he believed it was properly applied to such cases as he had reported. He was quite aware that the diagnosis was not fully established, that some of them were of the kind called scrofulous. He had tried to present the other aspect. He had tried to state that he would not make a diagnosis of syphilis upon the presence of dactylitis alone, but that where that symptom occurred with others, it added weight to them. Alone it establishes nothing. Some of his series had typical Hutchinson's teeth.

Certainly some cases have been reported even older than these mentioned by Dr. Wigglesworth.

NEW YORK NEUROLOGICAL SOCIETY.

MEETING held Tuesday evening, November 1, 1887. DR. C. L. DANA in the chair.

DR. BEVERLY ROBINSON presented a case of

APHASIA WITHOUT PARALYSIS.

The history had been furnished by the assistant house-physician to Charity Hospital. The patient was sixty-eight years of age, born in this country and admitted to Charity Hospital, August 25th of the present year. His previous history was negative in regard to syphilis. He once had had rheumatism in the knees, but the date was not known. His present difficulty dated from May, when he commenced to have headache. Subsequently he fell out of bed to the floor. He was able to crawl back into bed, but from this time his speech was affected. He was treated in Bellevue Hospital, and was from there transferred to Charity Hospital upon the date named. Upon entry he was apparently in perfect physical health, excepting speech. Objectively there were no signs of paralysis. His walk was slow but good. Possibly the right leg dragged a little. The dynamometer registered 20 with the right hand and with the left hand 10. The faradic reactions were normal in the upper extremities. In the lower extremities they were somewhat quicker and stronger upon the left than upon the right side. The sight in the right eye was as good as before the injury. The right eye was found more hypermetrophic than the left, but the optic disks showed the physiological cupping in both eyes. The urine was negative. When admitted the patient could speak only in monosyllables, using most frequently the phrases "Yes," "No," "That's it," and and "Exactly." He read the newspaper and apparently understood what he read. He also used gestures and explanatory words. When asked his age, as "Are you forty?" he would answer "No;" "thirty-two?" "no;" "forty-eight?" "no;" "sixty-eight?" "yes." If given a pencil and paper and told to write his age he would put down an 8 and in front of it a 6, adding "That's it." He could not write his name, writing John in the place of Isaac. It thus appeared to the speaker a case of amnesic and ataxic aphasia with agraphia, depending upon lesion of the foot of the left third frontal convolution. His own interest in it had been directed to the question whether lesion of this area would involve the intrinsic muscles of the larynx. On account of the difficulty of obtaining intelligent coöperation, however, a satisfactory examination could not be made. The treatment had consisted in the administration of fifteen grains of pot. iodid., t. i. d.

DR. DANA asked whether the patient could copy, and whether mirror writing was obtained with the left hand.

DR. ROBINSON did not think that the patient could copy, but would test the point.

DR. DANA suggested that his own name be not

used, and the President's was substituted. The patient wrote Charles Dane. Dr. Jacoby added another phrase and found that the patient wrote s for m and f for i.

Dr. Starr would rule out amnesia in the case. The terms amnesic and ataxic aphasia had respectively a sensory and motor significance. Here the patient apparently understood perfectly, and his difficulty was purely ataxic or motor.

Dr. Robinson explained that a few weeks ago the patient had not understood well and that even at the present time he would probably not understand all questions which might be put to him. Yet, during the last two or three weeks, he had very markedly improved.

Dr. Ball asked how carefully the question of sensory ability had been tested. When told to do certain things would he do them; also would he do the same when written directions were given him.

Dr. Robinson replied that the patient had complied with oral directions, that written directions had not been tried.

Dr. Dana asked whether the patient was able to utter exclamatory language. In some cases where ordinary speech was lost through lesion of the left third frontal convolution, profane or ejaculatory language was still obtained through the corresponding center upon the right side.

Dr. Robinson stated that the patient did not present this peculiarity.

Dr. Putnam Jacobi asked whether the test suggested by Dr. Ball could not then be made.

Dr. Ball directed the patient to take hold of Dr. Robinson's left thumb. The man hesitated and apparently failed to understand, but complied when directed simply to "Take his thumb."

Dr. Starr asked the patient whether he read the papers and understood them, and the man replied, "Yes, of course."

Dr. Ball mentioned the case of Dr. Charles Allen, aphasic for several years and now dead. This case, had, during most of the time, read and apparently understood, yet it was probable that he obtained the sense from leading words and that a large number of the words he did not understand at all. Probably the same was true of this case.

Dr. Robinson asked whether there was any recognized difficulty in the use of the intrinsic muscles of the larynx for phonation associated with the aphasic condition.

Dr. Starr had been interested in this subject through a paper by Dr. Delevan, in regard to a cortical centre for the larynx. For a year he had sent to Dr. Delevan all cases of hemiplegia coming to him at the Polyclinic and the Demilt Dispensary. Fifteen or sixteen cases had been examined without the discovery of any affection on either side of the larynx. He believes that no such case was upon record. It was certainly contrary to the general experience of neurologists to find any difficulty of phonation connected with aphasia. In fact, Dr. Ross, in his last edition, had stated that in the lesion of aphasia the muscles of the larynx were not affected.

Dr. Robinson had retained an impression that literature showed such cases. He had had his attention directed to the subject in this way.

Dr. Starr asked whether a patient could have this paralysis of the larynx without being hoarse.

Dr. Robinson replied that he could. He had seen patients with partial paralysis of a vocal cord who were not hoarse.

Dr. Gray stated that a distinction should be made between hemiplegias from lesion of the internal capsule, and those from lesions of other parts, particularly the pons and the medulla. Of six or seven cases in which hemiplegia was due to hæmorrhage, embolus, or thrombus in the internal capsule, he had had careful examinations made by competent laryngologists, and in none of them was there any paralysis of the laryngeal muscles. In hemiplegia from other causes, alteration of the tone of voice was sometimes obtained. In true and simple aphasia he thought that the voice was not affected.

Dr. Dana added that in pseudo-bulbar paralysis, the larynx was involved, the lesion being in the corpus striatum.

Dr. H. C. Coe followed, with a paper upon

THE SIGNIFICANCE OF PELVIC PAIN.

Pain was not a reliable indication of disease. Often an epithelioma of the cervix would cause less distress than a dislocation. The description of pain by the patient and the localization of its cause by the physician presented separate topics for thought. As described by the patient the pains of the pelvic region were, in general terms, an aching pain in the lower part of the sacrum, a shooting pain in the inguinal regions, and the gnawing pain of carcinoma. All of these pains could be referred to some lesion of the peritoneal or connective tissue, or both — to some plastic exudation not necessarily of great amount. The distress caused by a retroflexed uterus was much greater where there were adhesions than when there were not. It was fair to assume that this constant aching pain was due to the implication of nerves in the exudate. Laceration of the cervix, excepting that extending into the vaginal front, did not, in itself, cause pain. The cervix was a very insensitive organ and laceration was but a link in the chain of circumstances which resulted in pain. Malignant disease did not necessarily give rise to pain. Hart and Barbour say that there is no pain so long as the cervix only is affected. Hewitt says that the pain of cancer is due to localized attacks of peritonitis. The pain was earliest and most severe when the growth is in the body, thus differing from sarcoma of the body in which there was little pain. Possibly in this variety of cancer the intra-muscular nerves were involved in the growth. The shooting, darting, sickening pains associated with disease of the tubes was due to nothing but peritonitis. Hegar refers to cicatricial nodules in the broad ligaments, and even in the case of ovarian neuralgia it seemed probable that the pain was due to pressure upon the nerve before it entered the organ, rather than to changes within it. Otherwise this pain would not be relieved by the relief of perimetrial adhesion, as frequently occurred.

The inference was to give a guarded prognosis in regard to the relief of pelvic pain. If the pain, associated with a fissured cervix, was due to cicatricial nodules in the broad ligament, we might cure the laceration and the endometritis and yet the pain would continue. To remove the ovaries for the relief of pain was even more hazardous.

The speaker thought that gynecologists exaggerated the frequency of reflex pain. With Dr. Dana, he

considered anæmia the most frequent cause of vertex headache. Pelvic reflexes were found in the upper lumbar and intercostal nerves. He had not found sciatica of ovarian origin according to Dr. Mundé's suggestion. It might occur as the result of some exudates, but must be rare as a reflex pain. Dr. Mundé, himself, somewhat oddly remarks that this pain is relieved by a blister over the sciatic notch. Dr. Polk's plan of separating adhesions for the relief of pain presented scarcely less risk than the usual operations referred to. Treatment by electricity, according to the methods of Apostoli, gave the most satisfactory results. Reflex or transferred pains might also be due to inflammatory foci and might be treated in the same way.

DR. GRAY, as a neurologist, felt at a loss to know how to discuss such a paper. Many pains besides those of pelvic origin centered in the back, such as muscular pains and the pains of peripheral neuritis. He had himself often referred patients to competent gynecologists for examination, and had found nothing in the pelvis to account for pain over the sacral, lumbar, or coccygeal vertebræ. Yet, on the other hand, one could not deny the capricious vagaries which distinguish the truly reflex pelvic pain.

DR. PUTNAM JACOBI remarked that while the specialism assisted investigation, it was a misfortune to the patient. She did not consider that the writer of the paper had proved his position. Pelvic pain might be more definitely mapped out. The uterus, the central organ of the pelvis, was supplied by the lumbar plexus; and lesions of this organ were accompanied by pain in the track on the lumbar nerves. Two or three other definite points were known. Pain referred to the distribution of the femoro-cutaneous nerve, was the most characteristic accompaniment, not of ovaritis, but of ovarian neuralgia. Again, pain in the end of the spine might be spinal, ovarian, or endometrial in origin. A retroverted uterus without periuterine lesion would cause aching in the sacral region but no coccyodynia. The speaker considered pain from pelvic exudation rare and somewhat hypothetical. Even chronic peritonitis gave only a dull aching pain, which was quite tolerable, except when the patient was moving about. The worst case which she had ever seen, one which finally died from an exacerbation, was comfortable when in bed. The ganglion had been found frequently diseased in cases of pelvic pain, especially in those associated with posterior perimetritis; and in some cases of violent hysteria, it had been found atrophied. This ganglion, situated between the body and the cervix, was often the site of excessive tenderness and a permanent neuralgia might result from a peritonitis which would persist long after the removal of its cause.

DR. RANNEY quoted Dr. Beard as having said that the nervous system is like a mountainous region, in which echoes are returned with equal intensity from distant parts. This description was peculiarly applicable to pelvic pain. As a general practitioner he had frequently treated pelvic pain locally, without relief, in cases where it had finally disappeared upon the removal of a distant cause. It was not, in his opinion, possible to establish the seat of any pain unless removal of the supposed cause had established cure. He had failed to find compliance with this formula in the interesting paper under discussion.

DR. DANA stated that he had been disappointed often when sending patients with pelvic pain to gynecologists for examination; and that painful neuroses, even, had in some cases resulted from gynecological treatment.

DR. PECKHAM considered that the reader of the paper had underrated the suffering from direct pressure as a factor of pelvic pain. A retroflexed body or the hypertrophied cervix of an anteflexed body might cause a good deal of suffering by direct pressure upon the sacral nerves. Again, pain in the right or left iliac region might often be attributed to tension where with a shortened broad ligament and lateral deviation of the uterus there was pulling upon the ligament of the opposite side. Pain persisting after operation might later be found to have disappeared. The eye which looks on the sun retains for a time its image. Thus the nerves of other parts after prolonged irritation retain the impression of that irritation and the habit of pain after the removal of the cause. Time is thus required in these cases to perfect a cure.

The speaker endorsed the value attributed to electricity by the author of the paper. Whether it acted by direct influence upon the nerves themselves or by modifying the pelvic circulation was not apparent.

DR. STARR read a preliminary report of

THE STEVENS' COMMISSION.

The meeting adjourned.

Recent Literature.

Lessons on Gynecology. By WILLIAM GOODELL, A.M., M.D. Third Edition. Philadelphia. 1887.

The third edition of this well-known book comes to us, "thoroughly revised, and greatly enlarged." The result is that with all the charm of Dr. Goodell's style we have a work on gynecology which is thoroughly abreast of the times. No one who has ever read one of the author's lectures need be told how interestingly and with how much spirit he treats his subject. From beginning to end of the book it is interesting and instructive reading, and we heartily recommend it to any one, whether student or practitioner, who is interested in the subject.

The Diagnosis and Treatment of Eczema. By TOM ROBINSON, M.D. London: J. & A. Churchill, 1887.

It is unfortunate that a fantastic conception of pathological processes based upon the assumption of an "eczematous diathesis" and expressed in a desultory style of mixed metaphor and incoherent statement should obscure a writer's practical shrewdness. One patient "bursts out into" an eruption, another is "spattered" with vesicles, in others, notably children, eczema may be induced by "storms of uric acid," while another has a "distinct secretion upon his testicles." The skin is the canvas upon which the "eczematous picture" is painted, while the causes of eczema are the various "brushes" with which this "eczematous picture" is produced.

No statement is made, however, as to who may be the artist who employs such brushes to paint such pictures upon such canvas. In the opinion of the author, pityriasis rubra and lupus erythematosus are both varieties of eczema and "where an eczema occurs on both sides of the body, arsenic is of service."

After reading productions like the above, it is comforting to turn to Lord Bacon and to find that he says "Books must follow sciences and not sciences books."

G. H. T.

Differential Diagnosis of the Diseases of the Skin for Students and Practitioners. By CONDICT W. CUTLER, M.S., M.D. G. P. Putnam's Sons: New York and London. 1887.

This book consists almost entirely of a collection of tables of the differential diagnosis of all the diseases of the skin, and the impression derived from reading it, is much the same as that expressed by the Scotchman who was discovered absorbed in Webster's unabridged dictionary and being asked what he thought of the book replied that the stories therein were very pretty but "unco" short. These tables are prepared with care and thoroughness and presumably demanded an amount of labor in their production disproportionate to their usefulness.

G. H. T.

Food Adulteration, and its Detection, with Photomicrographic Plates, and a Bibliographical Appendix. By JESSE P. BATTERSHALL, Ph.D., F.C.S., Chemist, U. S. Laboratory, New York City. Published by E. & F. N. Spon, New York and London: 1887. 328 pp. 8vo. 12 Plates.

This work compressed into a volume of moderate size, the more salient features of the present status of food adulteration as it is exhibited in the United States. It treats of those articles which an extended experience has shown to be most liable to falsification, including however only those admixtures which have actually been detected by chemists of repute, within the past few years. It economizes space by omitting the many rather sensational forms of adulteration mentioned in many earlier treatises on the subject, the practice of which, if they ever did exist, now at least appear to have been wholly discontinued. The methods of examination given are those most approved of by standard authorities, although given often in a condensed form, from the more extensive works on food analysis. The colored photogravure plates of tea leaves, and of those sometimes substituted for them are very excellent. The appendix of bibliography, and American legislation relating to adulteration add greatly to the completeness of the work.

B. F. D.

— A correspondent calls attention to an instance of *la linguistique* from Cornil and Ranvier's "Manuel d'Histologie Pathologique," p. 1036: "*gros rein blanc* (whaxy kydney)."

— The British Trichological Association is the somewhat appalling title of a society which, it is suggested, bears by evolution a somewhat similar relation to the art of the barber that conservative dentistry bears to the crude tooth-pulling of a former generation. Trichopathy is to have a special hospital for its study in theory and practice, and if the society is successful in its aims, the bald heads will disappear from good society. The transcendental barber no longer means to be accosted by the classic inquiry of Mother Goose, but instead of saying how many hairs will make a wig, he will tell us what will make a wig unnecessary.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, NOVEMBER 24, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

SOURCES OF SYPHILIS IN THE FEMALE.

PROFESSOR FOURNIER, the French syphilographer, has compiled some statistics relating to the sources of syphilis in the woman. During twenty-seven years, he has made notes, in his private practice, of 887 cases, which 842 were of sexual, and 45 of non-sexual origin. In the second group, which constitutes a series of cases deserving, according to him, the qualification of "unmerited syphilis" ("the syphilis of innocents,") there were 7 cases in which the disease was inherited; 4 in which the disease was accidentally contracted in infancy; 8 cases of infection transmitted to wet-nurses by infants hereditarily tainted; 5 cases of midwives, who had contracted syphilis in their fingers or hands in the practice of their profession; 12 cases of "domestic contagion," derived from nursing infants belonging to nurses or servant girls that were syphilitic (these twelve cases were all observed in married women or young girls); 2 cases of syphilis transmitted by vaccine; 2 of syphilis communicated by catheterization of the Eustachian tube; 1 case consecutive to rape; and 4 of unknown derivation, but certainly not of venereal origin.

Of the 842 cases in which the disease was clearly of sexual origin, 366 were women of known dissolute habits, "women of the town"; 220 were married women; and 256 were persons whose social condition remained unknown.

Passing by the first group, that of the abandoned women, 65 of whom (17.7 per cent.) were play-girls (*filles du théâtre*), and analyzing the 220 cases of syphilis in married women, it appeared that of these there were 164 "that had been honestly and conjugally infected with syphilis"; that is, these women had contracted the disease from their husbands, and without any fault of their own. Of the 220 married women, 56 were doubtful cases; these latter had contracted syphilis from "lovers," for their husbands, when examined, were found exempt from syphilis; a few of them had been syphilitic before their marriage

With regard to the 256 patients whose social posi-

tion could not be satisfactorily ascertained, it seems probable that a certain proportion of them had become infected through no fault of their own; but, on account of the obscurity investing their history, Professor Fournier thought it best to include them all with the 366, making a total of 622 believed to be syphilitic from voluntary indulgence in vice. This left, out of the whole number of syphilitic cases, a percentage of 19, representing a certain number of persons who were suffering from all the horrors of this dire disease solely through the misdeeds of others, without having personally been guilty of any moral delinquency.

These statistics, says Professor Fournier, plead powerfully in favor of more energetic measures for protecting the public, and especially the innocent, against the ravages of this great social scourge.

UNIFORMITY IN OBSTETRIC NOMENCLATURE.

As to the importance of uniformity in obstetric nomenclature there can be no difference of opinion: if conventional symbols have been found convenient, even indispensable, to mathematicians and astronomers, it is quite certain that a uniform method of designating pelvic diameters, fœtal positions and presentations, and other data of exact knowledge would be of great advantage to all who read and teach obstetrics.

To Professor Alexander Russell Simpson, of Edinburgh, belongs the credit of taking the initiatory steps which are likely to result in the adoption of a universal nomenclature. In his introductory lecture[1] at the University of Edinburgh, October 19, 1887, Professor Simpson gave an entertaining and gratifying account of his recent visit to this country, and also a brief history of his own and his associates' efforts to perfect and present to the profession an obstetric nomenclature for the civilized world. The desirability of such a nomenclature was suggested by Professor Simpson to the International Medical Congress which met in London in 1881, and a committee was appointed of different nationalities to consider the subject and report at the next congress. At Copenhagen, however, the committee could report but little progress; but the subject was again referred to the committee for further conference, and subsequently Professor Simpson submitted a scheme to the Edinburgh Obstetrical Society. This scheme with some modifications suggested by the numerous specialists to whom it had been submitted, was presented by Professor Simpson to the International Congress in Washington, for final action. After a long discussion the scheme was referred to a committee consisting of Professors Simpson, Lusk, King and Miller for final revision: this revised report was unanimously adopted.

Copies of the proposed nomenclature are soon to be distributed to the various obstetrical writers and teachers of the countries represented at the congress, and although it is almost inevitable that some changes will be made, it is probable that the scheme will be essentially accepted.

While we cannot reproduce the proposed nomenclature here, we may say that it is essentially the one now followed in the Harvard Medical School. It is proposed, however, and it is indeed necessary, that when initial letters are employed, they shall be those of the corresponding Latin words; and it will therefore be necessary for us to substitute *dextra* and *læva* for right and left; O. R. P. will thus become O. D. P., while O. L. A. remains the same. The only decided change to us is the manner of designating presentations of the shoulder. Having said this much it is unnecessary for us to express our approval of the new nomenclature, and our hope that it will meet with universal acceptation.

[1] British Medical Journal, Nov. 5, 1887.

THE NEW MASSACHUSETTS "ACT CONCERNING COMMITMENTS AND TRANSFERS OF THE INSANE."

AT the close of the last session of the Massachusetts Legislature, a bill was passed which seems worthy of more consideration than was given to it by the body which passed it. We refer to the "Act concerning Commitments and Transfers of the Insane." This act provides, in the first place, that on and after the first day of July, 1887, each State Lunatic Hospital shall receive patients only from a certain district surrounding that hospital, the State outside of Suffolk County being divided into four districts. These districts, however, are arranged so as to take in the four older hospitals, Danvers, Taunton, Worcester, and Northampton, and patients from any of these districts may, if they choose, be sent to the new hospital at Westborough — an arrangement which would seem to be reasonably simple and satisfactory. The Suffolk County insane, however, are excepted from this provision. They "may be committed alternately and in equal numbers to the State Lunatic Hospitals at Danvers, Taunton, Worcester, the Westborough Insane Hospital, and the Boston Lunatic Hospital at South Boston; omitting from the enumeration such insane persons as, upon request of their friends, shall be sent to the Westborough Insane Hospital, the McLean Asylum, or any duly authorized private asylum." Further provisions exempt patients who are able to pay, from the provisions of this act, and put discretionary power as to its enforcement into the hands of the State Board of Lunacy and Charity.

The chief argument — and one which, to the ordinary mind, had a show of fairness in behalf of the establishment of a special hospital for the insane under homœopathic management — was that it was no more than right that the insane patient might be treated, if he or his friends chose, by physicians of the homœopathic school. Therefore, the hospital at Westborough was established, and provision was made for furnishing homœopathic treatment to such insane patients as desired it — a provision which has been

maintained in the act under discussion. The pauper insane in Suffolk County, however, are placed in a curious position by this act. If they desire homœopathic treatment at Westborough, they are privileged to claim it; but, if they object to homœopathic treatment, they must take pains to become insane during the terms assigned to the other hospitals, for, if they fall insane during the term assigned to Westborough, they have no choice but to be sent there and receive homœopathic treatment. Moreover, in spite of the great over-crowding of the Boston Lunatic Hospital, it must receive its quota of one-fifth of the Suffolk County insane in the year, which, at present, is impossible.

We do not know whether this act was framed with deliberation or in ignorance. It was certainly hurried through the Legislature at the close of the session without due deliberation. By its provisions, four-fifths of the Suffolk County insane have the privilege of choice between regular and homœopathic treatment in the hospitals. What justice or what fairness there is in excluding the other fifth from such a privilege, and in sending them to Westborough whether they wish or not, is known only to the framers of the act. To the ordinary mind, it does not seem to be either just or right, and certainly, if any class of the insane deserve fair treatment, it is the unhappy class in whom poverty is added to their disease.

ON THE PSYCHOLOGY OF JOKING.

IN a very characteristic lecture delivered before the Medical Society of London, October 17, 1887,[1] Dr. Hughlings Jackson calls punning a species of "mental diplopia." "It is," he says, "a caricature of normal mentation. A miser has been defined as an amateur pauper; the habitual drunkard is certainly an amateur lunatic; and in the same style of speaking we may say that punning is playing at being foolish; it is only morbid in that slender sense."

Further on, however, our lecturer treats the punster with greater respect. He thinks that it was a great advance when men began to value things for their beauty apart from their use; when over and above mind required for mere animal existence, he had some surplus mind for greater ends of life. "For the dawn of a sense of the merely ridiculous, as in punning and the simplest jokes shows the same thing as the dawn of asthetic feeling — surplus mind, something over and above that required for getting food, and for mere animal indulgence."

Dr. Jackson finally finds reason for the conclusion "that persons who are deficient in appreciation of jocosities in their degrees of evolution, are in corresponding degrees deficiently realistic in the scientific conception," "*pari passu* with the evolution of the sentiment of jocosity (playing at unreality) in the evolution of power of realistic scientific conception — from sense of the merely ridiculous with parallel realistic conception of simple things, up to sense of humor with parallel realistic complex things."

[1] Lancet, October 22, 1887.

MEDICAL NOTES.

—The Crematory of Paris will be opened during the present month. It is estimated that the furnaces will be able to consume 4,500 bodies annually, which is said to be about the average number of corpses leaving the hospitals in Paris during the year.

— A correspondent of the *Lancet* calls attention *à propos* of the recent anti-vaccination agitation in England to figures taken from a very instructive colonial surgeon's report for 1886, by Mr. P. B. C. Ayres, of Hong Kong:

Small-pox Hospital (European), 11 admissions, with one death — that is, a mortality of 9.1 per cent. Small-pox wards of Tung Wa Hospital (Chinese), 54 admissions, with 42 deaths — a mortality of 77.7 per cent. In connection with the European cases it is stated in the report that "most of the cases were of a mild type," but that the Asiatic cases were "mostly of the worst type, unvaccinated, and the majority children.

— Dr. Graham, of Canada, in a recent address, quoted the following account from Dr. Roouth of an interview held by the latter with the late Dr. Golding Bird a few weeks before his death. "He was" says Dr. Roouth, "then in the zenith of his popularity, and recognized by all as one of the ablest of our London physicians. I called upon him one morning with a relative to consult him. Several other medical men preceded me. His rooms were full, and I had to wait three hours ere I could obtain admission to his study and consult him about the case. I congratulated him on his success in practice. 'Yes,' he said to me, 'you are right; but I wish nevertheless, to make your remark a text for a little parting advice. You see me at a little over forty in full practice, my rooms are full and I am making my several thousands per annum (I think he said seven), and if I die to-morrow I do not leave as many hundreds to my family. All this I have done by sheer perseverance, unceasing hard work, and no holiday. But I am to-day a wreck. I have fatal disease of the heart, the result of anxiety and hard work. I know I cannot live many months and my parting advice to you is this: never mind at what loss, take your six weeks' holidays. It may delay your success, but it will insure its development. Otherwise you will find yourself at my age a prosperous practitioner, but a dying old man.' Six months after this conversation he was dead."

— A correspondent writes to the *British Medical Journal:* There are said to be at present no fewer than 2,600 soldiers in hospital in the Odessa district under treatment for ophthalmia of a more or less acute form. It has, it is stated, been found necessary to erect tem-

porary wooden hospitals for the accommodation of this extraordinary number of ophthalmic patients. No doubt the excessively hot, rainless, and dusty summer, and the dazzling sun-glare on the barren steppes outside where the garrison were encamped for four months, have this season abnormally swelled the ordinary number of patients from this disease, which every autumn crowds the military hospitals. In the northern provinces the hospitals are usually filled in the early spring with this class of patients, who suffer from the snow-glare of the protracted northern winters. One would naturally suppose that owing to the general prevalence of this affection in the Russian army, ophthalmia would not only be especially studied by the medical faculty, but the Russian military specialist would excel in theoretical and practical knowledge of this distressing complaint. But such is not the case. The greater part of these ophthalmic patients are, it is said, never treated by a qualified practitioner, but are left entirely in the hands of ignorant regimental dispensers. There are no available statistics to show how many Russian soldiers are every year rendered permanently blind through aggravated ophthalmia and neglect of treatment, but on the authority of the first ophthalmic medical men in Russia, the number is very large.

BOSTON AND NEW ENGLAND.

— The Medical Department of Dartmouth College graduated a class of twenty-eight on the evening of November 22d.

— The Boston Medical Library Association have recently received by the will of the late Charles Eliot Ware, M.D., the larger portion of his medical library. The gift comprises nearly two hundred and fifty volumes of standard medical works, and one thousand medical pamphlets and periodicals.

NEW YORK.

— On the 18th of November the "anniversary discourse" before the Academy of Medicine was delivered by Dr. Andrew H. Smith, who chose for his subject, "The Family Physician of the Future."

— Typhoid fever is said to have become so prevalent at Albany that the Mayor, at the instance of the Secretary of the Board of Health, has issued a proclamation requesting the citizens to boil the reservoir water before using it. The water is obtained from the Hudson River, and as the latter is unusually low, it is believed to be of even worse quality than is ordinarily the case. It is at all times, unfortunately, liable to contamination from the sewage of Troy, Cohoes, and other places along the upper Hudson, as well as that from the towns on the Mohawk.

— At the last meeting of the Society of Medical Jurisprudence and State Medicine, Dr. E. Miller Reid, of Baltimore, Chairman of the Section on Medical Jurisprudence of the American Medical Association, read a paper on "The Application of Legal Medicine to the Exigencies of the Times."

Miscellany.

ANTIPYRIN IN SEA-SICKNESS.

THE Paris correspondent of the *Lancet* writes: "The Société de Biologie has devoted part of its last two sittings to the discussion of the different means recommended for the relief of sea-sickness. A note was presented by M. Hantz on the best way of administering cocaine, and received without any expression of opinion. M. Dupuy said that sea-sickness was more severely experienced by dyspeptic subjects, and particularly those who had dilatation of the stomach. In eleven cases he had given antipyrin in doses of from two to three grammes for a few days before embarking, and the patients had all informed him that they had been free from sickness. M. Dastre said he had instituted a series of experiments upon animals, imitating as closely as possible the movements of 'pitching' and 'rolling.' He has found that there was an incredible displacement of the abdominal viscera, which strike against the diaphragm and cause the gastric uneasiness. The body struggles with these displacements by means of muscular contractions, and the respiratory rhythm accommodates itself to them. Professor Brown-Séquard remarked that this theory of visceral displacement was very old, and one which he had been able to verify in his frequent passages across the Atlantic. It was evidently the view entertained by Wollaston, who recommended Arago to place a pad over his stomach when he crossed the Channel. M. Maurel had no doubt as to the influence of the stomach, but thought the cerebral shock also played a part in the determination of the symptoms, inasmuch as the sickness always occurs when the boat is going down, never when it is being lifted up. The best preventive was lying on the back. Beyond the statement that sea-sickness is associated with dilatation of the stomach, and the hope held out by M. Dupuy that in antipyrin we now possess a remedy for it, there was nothing new in the views expressed by the different speakers."

TABLE OF FEES IN BOSTON IN 1785.

AT a meeting of the Boston Medical Society, December 7, 1785, the committee appointed to regulate the fees of practitioners in physic in this town having duly considered the business, report as follows, viz:

Midwifery, £2, 8*s*.
Capital operation, viz.: amputation of the large extremities, stone, trepan and the excision of large tumors, £5.
Amputation of fingers and small tumors, £1, 6*s*.
Tapping for dropsy, dislocations and fractures of large bones, £1, 8*s*.
Dislocation and fractures of large (?) bones, 14*s*.
Operation for fistula in ano according to the difficulty of the operation from 28*s*. to 100*s*.
Visit and passing the catheter, 12*s*., if frequently repeated 8*s*.
Dressing at surgeon's house, 4*s*.
Single visit, 4*s*.
Consultation, 1st, 12*s*., each visit after, 6*s*.
Rising in the night, 20*s*.; extra advice, 12*s*.
Decoction of red bark pr. lb., 8*s*.; common, do., 4*s*.
Huxham's tincture, pr. dr. 2*s*.; simple 1*s*., 6*d*.; red, do., 3*s*.
Emetic, cathartic, anodyne, each, 2*s*.
Blister large, 3*s*.; middling, do., 5*s*., small, 1*s*.

Visit in a vessel in the stream above the castle, 9*s.*; below the castle, 28*s.*
Sp't Mind, pr. dr., 1*s.*, powdered red bark, pr. oz., 6*s.*, common, do., 3*s.*
Alterative powders, 4*d.* each, pills, 3*d.*
Elec., pr. oz, 1*s.* 6*d.*
Juleps and mixtures, 9*d.* each.
Visit in the country beyond 8 miles, 6*s.* pr. mile; short of 8 miles, 4*s.* pr. mile.
Venereal cases, 60*s.*
N. B.— From the 25th of August, 1795, all the above charges were raised 50 pr. cent.

This schedule of fees were sent to the Boston Medical Library Association, by Dr. J. Nelson Borland of New London, Conn. It presumably belonged to his great-grandfather, Dr. James Lloyd. November 7, 1887.

MERCURIAL WASHES SOMETIMES DANGEROUS.

A CORRESPONDENT requests us to republish the concluding paragraph of a lecture on "Practical Legal Medicine," — given at St. Mary's Hospital by A. J. Pepper, M.S., late Examiner in Forensic Medicine to the University of London, etc., and published in the *London Lancet* of November 5, 1887, p. 905, — as a gentle *caveat* in the present fashionable practice of injecting and washing wounds and other surfaces with poisoning solutions.

Mr. Pepper says: "In concluding this lecture, I will direct your attention to a source of danger to life which, so far as I know, has not hitherto been noticed in the medical press. I refer to *poisoning from the use of perchloride of mercury in the form of very weak solutions* — for example, 1 in 1500 or 2000. I understand that in midwifery practice it is not at all uncommon to employ injections of the strength just mentioned for cleansing purposes, not only as a corrective against septic discharges, but also as a prophylactic Where the patient is free from organic disease of the kidneys one has little need to fear untoward consequences from the treatment under consideration. I am aware of two cases of death from acute inflamation of the bowels following closely on the injection of very weak mercurial solutions into the vagina shortly after parturition. As in each instance no other cause of the fatal complication could be discovered, there is little doubt that the acute irritative lesions in the intestines were due to the perchloride in the course of its elimination. The action of the salt was concentrated, so to speak, in this particular region by reason of grave renal affection. In one of the two cases I made a very exhaustive post-mortem examination. The whole of the small and large intestine was acutely inflamed. There were thousands of hæmorrhagic patches, punctate and irregular in shape. There were a few minute recent ulcers. The catarrhal congestion was extreme. Lymph was effused into the substance and upon the surface of the mucous membrane. Slight general peritonitis seemed to have started at the middle of the colon, where the intestinal lesion was more marked than elsewhere. The stomach was not affected. The kidneys were in an advanced state of fatty degeneration. No aperients had been administered to the patient, but a solution of bichloride of mercury (1 in 2000) had been injected into the vagina to prevent decomposition of the lochia. Profuse diarrhœa ensued, and continued until death. The body temperature was never raised, and latterly it was subnormal. I was at a loss to account for the ultimate cause of the diarrhœa and its fatal consequences until the circumstances were explained to me by an obstetric physician who was present at the necropsy, and who had witnessed a precisely similar case in his own practice. The lesson to be learnt from the foregoing narrative is — that even a very attenuated solution of a mercurial salt should not be employed as a vaginal injection without first ascertaining the state of the kidneys by an examination of the urine."

THE VERMONT NERVINE ESTABLISHMENT.

THIS institution is located at Burlington, Vt., and managed by Dr. A. J. Willard, late Superintendent and Resident Physician of the Mary Fletcher Hospital. Though still in its infancy, it is in successful operation, giving good promise of permanence and usefulness. The manager is desirous of securing endowments, to the end that the advantages which he offers may be made useful to nervous invalids who are unable to pay for such treatment as is desirable for this large and increasing class of patients. The Adams Nervine Asylum, the benefits of which are limited to residents of Massachusetts, has shown what may be done in this direction.

LAPAROTOMY FOR TUBERCULAR PERITONITIS.

A MOST interesting discussion on the treatment of this affection took place at a meeting of the Clinical Society of London, October 28th, with papers by Mr. Barwell and others. This *crux medicorum*, which has long been given over by medicine, seems to have been taken up enthusiastically by the broad shoulders of surgery. The *Medical Press*, commenting on the discussion, says:

"The number of cases on record in which laparotomy has been performed for the relief of tubercular peritonitis is now sufficiently large to enable us to form some opinion as to its propriety and as to its effects. Mr. Treves quoted thirty-six cases, in only six of which recovery did not take place, and this alone would suffice to warrant further trials when we consider the intractable nature and fatal tendency of the malady. A series of ninety-six cases brought before the Congress of German Surgeons yields almost, if not quite, as favorable statistics. In view of these successes, it may almost be laid down as a rule of treatment that, whenever we detect symptoms of tubercular peritonitis, the proper course is to open the abdomen and cleanse the peritoneum. The extraordinary impunity with which the peritoneal cavity can be manipulated under these circumstances is not the least interesting feature of the operation. The fact has long been recognized that, when the membrane has been the seat of chronic inflammatory changes, it is less apt to resent interference than under normal conditions, and advantage is taken of this to subject it to treatment which would have inspired surgeons of but a few years since with unmitigated horror."

Evidence was presented in the discussion that con-

comitant tuberculosis of the lungs is often favorably influenced by the amelioration of the abdominal disease. The accuracy of the diagnosis in some of the cases of most marked benefit from surgical treatment was confirmed by microscopical examination of the granulations with which the peritoneum was covered.

In several of the cases alluded to, the ascites had been first treated by aspiration, which, though it relieved the mechanical distress, did not have the effect of the more daring operation which was subsequently performed. Most operators attach great importance to the use of the drainage-tube, which is generally brought out through the abdominal wound, but Mr. Barwell did not employ it in the case which he brought before the Society, and objected to it as unnecessary, and even useless, seeing that a tube from the front could not be reasonably expected to drain the abdominal cavity of a patient lying on the back. In any case, he maintained that it was preferable to give the patient a chance of doing without it for the first twenty-four hours, even if it had subsequently to be inserted. Although Mr. Treves was firm in his advocacy of the use of the tube, which he considered a principle of the treatment, one of his cases tended to prove the contrary, for, although the tube was inserted, subsequent accumulation took place, in spite of all the efforts made to obtain a free discharge. It is not without interest to note that in this particular case, the patient being a child, Mr. Treves went a step further, and injected a solution of iodine, again not only with untoward result, but with positive advantage to the patient, whose temperature then and there fell to normal, and never after rose.

ANTAGONISM AMONGST BACTERIA.

DR. C. GARRÉ, of Basel, has found in cultivation of micro-organisms that there is a sharp antagonism amongst some, probably through their excretions (*Deutsche Med. Wochenschr., No.* 27, 1887. *London Medical Record, October*, 1887). For instance, some aërobes, which spread only on the surface of gelatine, in a short time so alter the nutritive substratum that certain other micro-organisms cannot exist in it. He says that this fact has not been taken into consideration as yet, though various observations made in the cultivation of cholera and typhoid-bacilli, and experiments on the multiplication of pathogenic bacteria in water have shown that there is probably antagonism between the pathogenic species and saprophytes. To elucidate this, Garré adduced the following facts. A non-liquefying cultivation was planted on the surface of meat-peptone gelatine. After complete development, it was removed with a sterilized platinum spatula. Other micro-organisms were then planted on the remaining sterilized medium. A comparison of the retarded growth with another cultivation gives the degree of antagonism between the two species. With liquefying species the nourishing substratum was filtered through potter's earth, and gelatine added afterwards. In this way the mutual relations of a number of pathogenic and non-pathogenic species were tested. One species proved to be pre-eminently antagonistic; namely the bacillus fluorescens putridus, described by Flügge. It excretes specific, easily diffusible substances, the oxidation-products of which tinge the gelatine with a greenish color, and hinder the development of the one set of species, whilst it has no effect whatever on the other set. If such cultivations were removed from the gelatine in the manner described on the third or fourth day, and the staphylococcus pyogenes aureus inoculated on this "fluorescens medium," no development took place, nor did the typhoid-bacillus, the pneumonia-bacillus, etc., develop. The Asiatic cholera-bacillus and the bacillus-mycoides developed but slowly, but the bacillus-anthracis and the comma-bacillus had a luxuriant growth. It appears, therefore, that the bacillus fluorescens putridus is a pronounced enemy of the pneumonia and typhoid-bacilli, and by its implantation the nutritive substratum is protected against them. The reverse, however, does not hold good. There are, however, so-called symbiotic bacteria that flourish side by side, and some even, which Garré terms metabiotic bacteria, whose existence depends on the presence of others. Garré asserts that these facts are not confined to experiments in test-tubes. He points to the strife between saprophytes and cholera-bacilli in ichor and canal water, the cholera-bacilli always succumbing. Such conditions may occur in the intestines, and may in some cases lead to the erroneous supposition of natural indisposition to cholera. The torpid development of periostitis of the jaw, when the staphylococcus must come into conflict with other species, is explained by Garré on the supposition of such antagonism. He closes with the two following points as regards immunity. 1. That immunity from a certain disease may be caused not only by micro-organisms of like species (vaccination), but perhaps by entirely different microbes. 2. Antagonism quickly produced in the living body may favorably affect infectious diseases already existing. If this be true, a wide and fruitful field is open up to bacterial treatment.

MEDICAL APHORISMS.

A CORRESPONDENT signing himself "Artz," sends to the *Canada Lancet* the following professional aphorisms of Amédée Latour:

1. Life is short, patients fastidious, and the brethren deceptive. 2. Practice is a field of which tact is the manure. 3. Patients are comparable to flannel — neither can be quilted without danger. 4. The physician who absents himself runs the same risk as the lover who leaves his mistress; he is pretty sure to find himself supplanted. 5. Would you rid yourself of a tiresome patient, present your bill. 6. The patient who pays his attendant is but exacting; he who does not is a despot. 7. The physician who depends on the gratitude of his patient for his fee is like the traveller who waited on the bank of a river until it finished flowing, so that he might cross to the other side. 8. Modesty, simplicity, truthfulness! cleansing virtues, everywhere but at the bedside; there simplicity is construed as *hesitation*, modesty as *want of confidence*, truth as *impoliteness*. 9. To keep within the limits of a dignified assurance without falling into the ridiculous vauntings of the boaster, constitutes the supreme talent of the physician. 10. Remember always to appear to be doing something — above all, when you are doing nothing. 11. With equal and even inferior talent, the cleanly and genteely-dressed physician has a great advantage over the dirty or untidy one.

Correspondence.

THE CONDITION OF THE NEW YORK QUARANTINE INDEFENSIBLE.

NEW YORK, November 19, 1887.

MR. EDITOR,—Will you please oblige me by publishing this correction of mistake in your summary of the proceedings of the recent meeting of the American Public Health Association, in your issue of 17th inst., so far as they relate to my remarks on the condition of the New York Quarantine Station? So far from attempting to defend it, I distinctly declared it to be disgraceful to the State. That while in its conception and plan, I believed it to be the most complete quarantine establishment in the world, it had never been finished and adequately equipped, and that much that had been done up to fifteen years ago, had been neglected and allowed to decay in the face of continuous dangers. But, nevertheless, such measures had been extemporized in the recent emergency, as, in my judgment, have been effectual in preventing any danger of the introduction of Cholera by the *Alesia's* and *Britannia's* passengers. Truly yours,

A. N. BELL.

— Sir William Gull, the eminent English physician, who has lately suffered from an attack of hemiplegia is recovering.

— On Hospital Sunday at Birmingham, England, the Jews arranged to hold a service so as to be in harmony with their Christian fellow citizens in the charitable movement. The theatres also joined in the work, the orchestra furnishing the musical part of the programme, and a clergyman delivering an address.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 12, 1887.

Deaths reported 1,873: under five years of age 630; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 331, consumption 245, acute lung diseases 263, diphtheria and croup, 158, diarrhœal diseases 56, typhoid fever 44, scarlet fever 35, malarial fever 14, cerebro-spinal meningitis seven, puerperal fever seven, measles six, erysipelas five, whooping-cough three. From scarlet fever, Boston 13, New York nine, Somerville three, Philadelphia, District of Columbia and Chelsea two each, Portland, Cambridge and Newburyport one each. From malarial fever, New York six, New Orleans four, Baltimore three, Lawrence one. From cerebro-spinal meningitis, New York, Baltimore, Worcester, Fall River, Chelsea, Haverhill and Newburyport one each. From puerperal fever, Pittsburgh three, New York, Philadelphia, Charleston and Chelsea one each. From measles, New York four, Baltimore two. From erysipelas, New York two, Baltimore, Pittsburgh and Somerville one each. From whooping-cough, Baltimore two, New York one. From small-pox New York one.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending October 29th, the death-rate was 21.5. Deaths reported 3,808: infants under one year of age 920; scarlet fever 138, measles 76, diarrhœa 65, whooping-cough 68, fever 50, diphtheria 45, small-pox (Sheffield 19, London, Bristol and Birmingham one each), 22.

The death-rates ranged from 13.1 in Leicester to 32.1 in Preston; Birmingham 18.1; Bradford 20.0; Brighton 19.9; Halifax 15.2; Hull 15.1; Leeds 21.0; Liverpool 24.8; London 21.5; Manchester 25.0; Newcastle-on-Tyne 23.6; Sheffield 24.6; Sunderland 18.1.

In Edinburgh 21.2; Glasgow 24.4; Dublin 32.1.

The meteorological record for the week ending November 12, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Nov. 12, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 12, 1887, TO NOVEMBER 18, 1887.

BYRNE, C. B., captain and assistant surgeon. Relieved from temporary duty at Fort McHenry, Md., and will return to his proper station, Washington Barracks, D. C. S. O. 242, Division of the Atlantic, November 11, 1887.

WALKER, F. V., first lieutenant and assistant surgeon. Relieved from duty at Post of San Antonio and assigned to duty at Fort Ringgold, Tex. S. O. 150, Department of Texas, November 8, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 19, 1887.

RIXEY, P. M., passed assistant surgeon. Ordered to the Naval Dispensary, Washington, D. C.

SOCIETY NOTICES.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION. — A Southern Surgical and Gynecological Association has been formed with the following officers: Dr. W. D. Haggard, of Nashville, Tenn., President; Drs. R. D. Webb and J. W. Sears, both of Birmingham, First and Second Vice-Presidents, respectively; Dr. W. E. B Davis, of Birmingham, Alabama, Secretary; and Dr. H. P. Cochrane, of Birmingham, Treasurer.

NORFOLK DISTRICT MEDICAL SOCIETY. — A meeting for Scientific Improvement will be held at the Hall of the Roxbury City Guard, 67 Warren Street, Roxbury, November 29, 1887, at 7.45, P.M. Communications: I. "Lessons from a Year in Obstetrics. Topics: Antisepsis: Abdominal Palpation; Ante-partum Hemorrhage; Uræmia," H. W. Broughton, M.D II. "The Examination of Drinking-Water," J. A. Tanner, M.D. Dr. Benjamin Cushing, Dr. D. D. Gilbert, and Dr. E. P. Gerry, are expected to take part in the discussions. Members of other Districts are cordially invited to be present and participate.

S. ALLEN POTTER, M.D., *Secretary*.

PULMONARY TUBERCULOSIS AS A SEQUEL TO ORDINARY PLEURISY WITH EFFUSION.[1]

BY HERMAN F. VICKERY, M.D., OF BOSTON,
One of the Physicians to Out-patients, Massachusetts General Hospital, and Assistant in Clinical Medicine, Harvard Medical School.

THE object of this paper is to show the possibility of a pleurisy with serous effusion being, clinically, the first step towards consumption, or, in other words, that a man who has heretofore been apparently sound, and falls ill with acute pleurisy, may be destined, finally, to succumb to pulmonary tuberculosis.

Undoubtedly, this proposition will be accepted by many unhesitatingly. There is ample authority for making it. We may instance Gerhardt,[2] Niemeyer,[3] Germain Sée,[4] Bartholow,[5] Anstie,[6] and Donaldson.[7] Strümpell[8] says: "In an ætiological sense, we must declare the larger part of the ordinary 'pleuritic effusions,' which, clinically, seem to be primary, to be tubercular. . . . The further course of the cases, if we can watch them for years, almost always permits us, finally, to recognize the tubercular nature of the disease." Indeed, some have claimed that every pleurisy is tuberculous in its origin.

On the other hand, Donaldson[9] states that "of fifty-three cases reported by Blakiston, not one became phthisical during several years after recovery from the pleurisy." And Flint[10] regarded pleurisy as having "little or no tendency to eventuate in phthisis."

In August, 1884, Chauffard and Gombault[11] made a preliminary report of certain experiments having a direct bearing upon our subject. They injected into the peritoneal cavities of twenty-three guinea-pigs a small amount of fluid obtained from serous cavities; twenty of the twenty-one cases from whom the fluids were taken had pleuritic trouble, and one peritonitis. In some cases, however, the fluid was purulent, but in the rest it was serous. Other animals were kept with the inoculated ones, so as to control the experiments, and scientific cleanliness was observed. Of the twenty-three cases, in four there was no result, death being too speedy, in nine there was a negative result, and in ten there was positive tuberculosis. The experiments permitted them, in certain instances, to affirm the tubercular nature of a pleurisy which had apparently terminated in complete recovery.

Dunin, writing upon the present subject, says in the *Gazette Hebdomadaire* of May 6, 1887: "In the majority of cases, there is reason to suspect the tubercular diathesis." He evidently regards this as a conservative statement. He feels able in many instances to distinguish the portentous cases from the benign. The tubercular case is usually young. Being in good health, he is suddenly seized with high fever, perhaps a chill, great pain in the side, and sometimes with somnolence, severe headache, or delirium; the course is tedious; the amount of effusion may not be large, but it is not readily absorbed, and, even if we aspirate, the fever persists, so that convalescence may be delayed for weeks or months.

Usually, the fluid is serous. It is sometimes excessively coagulable: out of three of this sort, two have died of phthisis, and the third, although still well himself, has lost a brother from the same disease.

The benign form is chronic, and insidious in its onset, the patient seldom seeking medical advice till, after some weeks, the effusion begins to cause dyspnœa.

Having myself become greatly interested in the matter, I will venture to report a number of positive cases, of which four have been kindly described to me by others, and the remainder have come under my personal observation.

Unfortunately, I have not been able to follow up a series of cases, so as to learn what proportion of the whole number developed pulmonary trouble eventually, but I should certainly expect to find that proportion much greater than was observed by Flint or Blakiston.

CASE I. Reported by Mr. A. F. Chandler, Medical Student. R. B., aged twenty-three. Family history good. Habits alcoholic. In April, 1886, after exposure to wet and cold, he began to have a slight cough, with scanty, white, and frothy expectoration. He was tapped in the left side, and soon became much better; but the cough persisted and grew worse, till, in October, 1886, almost all the rational and physical signs of phthisis were present. The changes were mainly confined to the upper third of the left lung, and, although no disparity in the respiratory movements of the two sides could be detected, there was a slight dulness in the lower portion of the left chest, and respiration was slightly diminished there also, but it was vesicular in quality.

CASE II. The notes of this and the following case were kindly furnished me by Dr. G. M. Garland, whose patients they were. Miss Minnie R., aged twenty-seven, had never had any thoracic trouble before October 1, 1884, when she had a chill, followed, forty-eight hours later, by pain in the right axillary region, and cough, with scanty expectoration.

November 9th, three pints of serum were removed by Dr. Garland. The patient then gained in every way, but the cough persisted. One year later, she died of consumption at her father's home in Germany.

CASE III. A commercial traveller, aged forty-one, had a large pleuritic effusion on the right side in 1881, which subsided without tapping, but convalescence extended over several months. He then remained well till November, 1886, when he "took cold" and had an incessant cough, losing ten pounds in two weeks. There was no expectoration, nor were there any night-sweats. On examination, the right side seemed to be slightly fuller than the left, and to move less with respiration than did the left. There was normal resonance over both fronts; behind, the right subscapular region was slightly dull, and gave a diminished respiratory murmur. On June 4th (three days ago), the patient applied again to Dr. Garland for relief. He had lost thirty-three pounds. The temperature was 99.5°, the pulse 100, and the physical signs were such as to warrant Dr. Garland's statement that "the man evidently has tuberculosis of the right apex."

CASE IV. Reported by Mr. L. S. Stevens, Interne at the Massachusetts General Hospital. Charles M., aged thirty, printer. Tendency to phthisis on the mother's side. With the exception of an attack of

pleurisy when young, and of fever and ague in 1878, he had been in perfect health until March, 1880, when he was treated in the Massachusetts General Hospital for an acute pleurisy on the right side, with moderate effusion, for which he was tapped. The physical signs at the time were confined to the base of the right chest. Reported several months later, when there was still dulness and feeble respiration at the right base. Re-entered the Hospital February, 1887, for "rheumatism and other disorders," at which time there was obtained a history of progressive loss of flesh, strength, and appetite, dating back three months, with night-sweats, but no cough. Signs in the chest were found throughout the upper third of right side, and at the extreme left apex, and showed, besides catarrh, a slight consolidation, limited to the right side.

CASE V. Mr. F. E. L., of Malden, aged twenty-six, examined April 14, 1887. Family history good, except that one sister died of consumption nine years ago. Three years ago, having been well previously, he had an acute attack of pleurisy, which lasted six weeks. He was tapped twice successfully, and about two quarts of "lightish-green," clear fluid were removed each time. Upon a third aspiration, nothing but a little blood was obtained. From this illness he never fully recovered. There is now, occasionally, a slight diarrhœa. Both lungs present the physical signs of advanced phthisis. He weighs ninety-six and one-half pounds, or twenty-eight and one-half pounds less than in 1884.

CASE VI. J. M., aged sixty, seen March 25, 1887. Always well till he was forty years old. Sixteen years ago, was in bed three weeks "with a cold," but regained his health. Three years ago, he had palpitation and dyspnœa on exertion, with a slight cough. Three pints of clear fluid were withdrawn from the left side. He recovered, and was apparently well till November, 1886, when he "took cold." He has since then lost fifty pounds. The pulse is 96. There are at both summits dulness, bronchial respiration, increased vocal resonance and fremitus, and crackling râles. The right side is the worst; that is, the side opposite the pleurisy.

CASE VII. P. F., aged about twenty, seen June 3, 1887. Entered Massachusetts General Hospital, August 22, 1881, with symptoms of acute pleurisy. He was aspirated, and fifty-six ounces of serum were removed. He was discharged "well," but he is now feeble and emaciated, and presents signs of consolidation at the left apex and the right base, with coarse, crackling râles and bronchial respiration.

CASE VIII. Mr. N. H. M., aged thirty-seven, seen in February, 1887. A sister of his father died of phthisis. Eight years ago, he had pleurisy with effusion, not having been subject to cough previously. Recovery was apparently complete. One year ago (seven years after the pleurisy), had a hacking cough, which has now returned. He has lost flesh and strength. There is dyspepsia, and also a tendency to diarrhœa. At the top of the right lung there is slight dulness, with numerous moist râles in the upper third of both lungs. The expectoration is in part frothy, and in part muco-purulent, with some cheesy-looking particles. Repeated examinations show large numbers of the specific *bacilli tuberculosis*. Dr. Harold Ernst was kind enough to confirm this last observation, after looking at several slides which I took to him.

CASE IX. J. C., coachman, aged forty-one. Lost a mother, brother, and sister of phthisis. He was never ill up to three weeks before entering the Boston City Hospital, in November, 1884. The first symptoms were a slight cough, with very scanty expectoration, and a sharp, "catching" pain in the left side. Upon entrance, the record states that there was flatness in the left front, below the third rib, and over the entire left back. Vocal fremitus was absent, ægophony was present, the heart's apex was in the median line of the body. At the end of three weeks the effusion had cleared up, and the patient was discharged "well." Just one year later, however, having been in apparently good health meanwhile, he entered the Massachusetts General Hospital with nearly identical symptoms, except that it was the right side, and not the left. The diagnosis was pleurisy with effusion, and the case seemed sufficiently typical to be shown to the students as an instance of that affection. An unfavorable prognosis as to the man's future health was expressed, because the pleurisy had now affected both sides. Two weeks after entrance he was discharged "well," to go to the Convalescent Home. Four days before he left, the record gives: "Good resonance and respiration in both fronts. A few friction-murmurs throughout right front. Behind, dull below middle of right scapula, and nearly flat below the angle of the scapula, with feeble respiration and voice-sounds. Coughs but little. Temperature normal."

September 27, 1886 (about two years after the first attack of pleurisy), the patient entered the Massachusetts General Hospital again, with slight changes in the left lung, but marked changes in the right lung, the lower portion of which had probably never expanded after the pleurisy. He was evidently in consumption. In a short time he developed an ischio-rectal abscess, which was opened.

November 11th. He left his bed to walk a short distance, but he fell, fainting, and soon died. No autopsy was allowed.

CASE X. J. S., aged thirty-two, teamster, seen in May, 1887. For fifteen years, he has been subject to chronic pharyngitis. Otherwise, he was well till five years ago, when he began to experience discomfort in the left side, and had a cough, with scanty expectoration. At the end of about four weeks he was aspirated, "two quarts" of "tea-colored" serum being removed. He now complains of a cough, worse at night, with a viscid, whitish expectoration. The temperature was 100° F. At the inner end of the left clavicle there was dulness, with broncho-vesicular respiration and fine, crackling râles. The signs, though of limited extent, seemed distinct.

The reason of this sequence of diseases is given variously by different authorities. Some believe that the pleurisy is, in reality, preceded by minute tubercular foci in the lungs. Dunin thinks that this is always the case. To others, it seems reasonable to suppose that in a certain number of cases the pleuritic effusion, by compressing the lung and hindering its respiratory movements, renders it a favorable nidus for the ubiquitous bacilli. Thirdly, the tubercles may originate in the pleura, and thence extend. The work of Chauffard and Gombault above referred to, would seem to point in this direction; and Delafield [12] reports the case of a seaman, who had a large effusion of clear serum into the right pleural cavity, and in whom tu-

[12] American Journal Medical Sciences, October, 1880.

bercles were found in the right pleura, and only there.

Coming now to the practical lesson, it is briefly this: in all cases of pleurisy with effusion, long after apparent recovery, the patient is in danger of pulmonary tuberculosis, and demands all possible hygienic precautions.

MULTIPLE NEURITIS. CASES.[1]

BY GEORGE B. SHATTUCK, M.D.,
Visiting Physician, Boston City Hospital; Instructor in Clinical Medicine, Harvard Medical School.

ALTHOUGH I find it necessary at the very outset of my remarks this evening, gentlemen, to warn you that I have no new theories to advance, and no really new facts, even, to record, I still shall abstain from going farther in that direction and apologizing for my choice of a subject, and my mode of treating it under these circumstances.

The earliest recognizable and suggestive clinical description of multiple peripheral neuritis, as caused by the use of alcohol, originated in Boston with Dr. James Jackson, in 1822.[2] Subsequently, the earliest detailed report in this country of cases of multiple neuritis, with accurate specifications as to the anatomical situation and the supposed pathological processes involved in the affection — the earliest, at least, of any with which I am acquainted — proceeded from another Boston source, Dr. S. G. Webber (1884),[3] and mainly from cases presenting themselves at the Boston City Hospital. Again, last year, Boston and its City Hospital furnished another contribution to the subject in a paper by Dr. C. F. Folsom, read before the Clinical Section of the Suffolk District Society.[4] It, therefore, seemed to me not amiss that this subject should be brought up in Boston again, and that the records of the City Hospital should contribute their story from the point where it had previously been left. Nor do I feel that, except, possibly, to a small number of nervous specialists, in doing this I am really in any sense thrashing out old straw. From Dr. Jackson's description of a complex of symptoms which attracted his notice in 1822, the subject received no attention whatever until 1852, when it was taken up by Magnus Huss, of Sweden, in a work on chronic alcoholism. It was not until the end of 1883, as Dr. Allen Starr states in last year's excellent Middleton Goldsmith lecture, the best *résumé* of the whole question of multiple neuritis which has as yet appeared, that the third stage in its history, that of pathological discovery, could be considered as terminating. Not until that recent date, had the symptoms of the affection been recognized as constituting a distinct, clinical picture; had previous hypothetical lesions in the spinal cord been abandoned, and the pathology of the disease been described.

Since 1883, an elaboration of the symptoms, as bearing on diagnosis and differential diagnosis, and of the pathological processes, has been going on. But as late as the beginning of this year, Dr. Starr, whose bibliography would indicate a pretty comprehensive research, mentions finding only about one hundred published observations of cases.

Moreover, I am convinced that still the general practitioner is not on the lookout for the complex of symptoms, and, in most cases, does not understand or recognize the disease when presenting itself to his observation, as it unquestionably has in the past, does now, and will in the future, with sufficient frequency to make it really important that he should; especially as there is no reason why he should not care for many of these cases himself if he chooses to, and, in any event, he would, at least, know what was the best disposition to make of them, and what to say with reference to the probable course and prognosis. Within a few days a typical case of alcoholic neuritis has come under my care, in which the diagnosis previously made was, "incipient paralysis."

When Dr. Webber read his paper before the American Neurological Association, in June, 1884, he had found the records of six cases without autopsies, and twelve cases with autopsies. In addition to, and distinct from these, he mentions eighteen cases as having entered the Boston City Hospital in the autumn and winter of 1883–84, in his own service, or that of Dr. J. H. Denny — in the nervous service. Of these, he reported four in detail. In May of this year Dr. Folsom reported three cases — two from the City Hospital service. In addition to these two cases, the records show that fifty-one cases of multiple neuritis have been observed and recognized at the Hospital since the summer of 1884. These have all occurred in the nervous service, or been transferred to it, except one case, which entered and died in one of the other services. Of these cases, twenty-nine have been in males, and twenty-two in females; and, I think, in no case has the patient been under twenty years of age, nearly all being between thirty and fifty years old. I have selected eleven cases for reporting in as brief a manner as possible.

The predominating cause of neuritis among such a class of patients as the City Hospital receives, and, indeed, among all those affected by it, I believe, is alcohol, and the abuse of alcohol produces this group of symptoms more often among women than men, though it so happens that a greater proportion of men have entered the Hospital. Phthisis is beginning to be recognized as a not infrequent cause of the affection, and I have, consequently, included some cases. It is difficult, however, to get such illustrative cases as would be desirable among our patients, and, had I had more time at my disposal, I should have looked for them elsewhere. Phthisis is too apt to be preceded or complicated by an alcoholic history. There are two cases in which the underlying cause could not be ascertained, probably owing to the limitations of our means of information, though, in each case, especial pains were taken to get at all sources of information. I am fully alive to the unavoidable imperfections of hospital records, even when carefully revised and controlled. The only case among those recorded breaking out in a sudden, acute, explosive manner, suggestive of an acute disease with an infectious origin was the Case I, reported by Dr. C. F. Folsom in his paper last May. That case followed positive exposure to cold and wet. He was under my care for some months after the expiration of Dr. Folsom's service. I questioned him carefully many times, and I could not evolve any reasonable source of exposure to infection from his statements in regard to his surroundings. There is no other case among those gone over which lends any countenance to the German theory that cases

of multiple neuritis, as such, are due to a specific germ. It may, however, very well be that beri-beri has its specific microbe, and that multiple neuritis is often an accompaniment of beri-beri. Œdema and swelling of joints were neither marked nor frequent features of the cases recorded.

Personally, I have not seen any cases which could be traced to such toxic influences as arsenic, lead, sulphide of carbon (to which rubber-workers are exposed), etc.

Brissaud[5] thinks that acute poisoning by a large amount of arsenic is necessary to produce multiple neuritis with paralysis, that it does not follow chronic poisoning; if such a position were substantiated, it would, of course, simplify the consideration of arsenic as a possible cause in a given case.

I have not gone into questions of differential diagnosis, except incidentally. The distinguishing points between multiple neuritis and acute anterior poliomyelitis, Landry's ascending paralysis, locomotor ataxia — the forms of nervous affections with which it may sometimes, but not often be confounded — have been several times differentiated. I think that the cases I report, if regarded from the combined points of view of history, symptoms, and course, will not be challenged as probably ranging themselves under the category of multiple peripheral neuritis.

I have not dwelt on the question of treatment especially. It is a question whether any given treatment is applicable to any number of cases. In the acute stage, pain must be relieved as it occurs; subsequently, when pain has subsided, electricity, rubbing, and massage are useful in correcting and restoring the paralyzed muscles. Nutritious food, and enough of it nearly always; stimulants almost never; arsenic, salicylic acid, quinine, antipyrine sometimes, are indicated.

In the determination of the electrical reactions of cases in my own service, I wish to acknowledge the attentive assistance of my senior house-officer, Dr. C. F. Carter.

CASE I. *Alcoholic Neuritis; no Phthisis. Two Attacks.* E. M., a male, aged twenty-six years, furniture polisher, single. No specific history. No history of exposure to cold. Uses alcohol "a little." About the first of May, 1883, began to have sharp pains in the feet extending gradually into the calves, knees and thighs. These pains were followed by numbness in the legs and later in the thumbs, loss of power in legs and hands, burning sensation in the feet. After being in bed ten days these symptoms diminished. When admitted to the hospital, July 11, 1883, in Dr. Webber's service, was able to move arms and legs but complained of weakness. Could move feet but little. Paresis of extensors of hand. Sensation good. No noticeable atrophy of arms and legs. No cutaneous reflexes. Patellar reflexes absent. No ankle clonus.

July 13th. No lead line on gums. Complete paralysis of the extensors of the feet. The tibialis anticus and peronei do not react to faradism, extensors of the arm react feebly.

July 31st. Faradism administered every other day. Improving rapidly. Can move feet very well; the muscles react somewhat to faradism.

September 6th. Walks about fairly well, though complaining of some pain in the feet; has difficulty in raising the toes when walking, the feet being thrown forward and the toes striking the ground first.

Discharged October 30th, at which time he was able to walk as well as ever he could, but the electrical reactions were still diminished. Duration in hospital three and one-half months; total duration six months.

Admitted second time to hospital June. 15, 1885, in Dr. C. F. Folsom's service with symptoms similar to those reported. Had continued the use of alcohol since his discharge.

June 17th. Patella tendon reflex absent; increasing loss of power in grasps of hands; could rise from chair only with assistance; when standing would lean far forward and could not maintain equilibrium with the eyes shut.

June 27th. Extreme sensitiveness to pressure over main nerve trunks of both arms and legs, but no pain on motion.

July 22d. Could walk the length of the ward without assistance. Previously mentioned symptoms diminishing. Discharged from the hospital September 14th, much relieved, and has not been heard of again. Duration in the hospital, two months.

CASE II. *Alcoholic Neuritis with subsequent Phthisis.* M. T., aged twenty-seven years, female, single, domestic, with an unimportant family history. Had been a hard drinker at times and for three or four weeks before admission to hospital, September 5, 1885, in Dr. Folsom's service under care of Dr. Morton Prince. She had had difficulty in walking for several days, and numbness in both legs for two weeks. Absence of the patellar reflex, patches of anæsthesia on the inside of the legs. Walked with difficulty on account of staggering, which she attributed to weakness; complained of pains in the calves. Hand grasps of fair strength, no ataxia of the hands; tremor when extended. Reaction of degeneration in muscles of both legs.

General condition improved slowly up to October 18th, when signs of incipient phthisis were noticed and these developed steadily, but the patient was discharged relieved of the neuritis, January 13, 1886. Duration, five and one-half months.

CASE III. *Alcoholic Neuritis.* M. K., aged thirty years, male, employed in a brewery, loading the teams. A large, strong man, who, up to the beginning of present attack, had enjoyed good health. Had been in the habit of drinking a good deal of beer in the early morning before breakfast, after loading the wagons. Entered the hospital, September 17th, (in Dr. Denny's and Dr. Shattuck's service.) Temperature, 99°, pulse, 72; tongue bright red like raw beefsteak; feet slightly swollen and œdematous; pupils equal, reacting to light and accomodation, slight nystagmus on looking to the right; grasps equal but both weak; knee-jerks and plantar reflexes absent; tenderness on pressure over both posterior tibials; tremor of extended hands. It was learned from patient's wife that he had been sick in bed for sixteen days before coming to the hospital, having lost the use of his legs at the beginning of that period; he had had double vision and been "queer," especially in regard to his memory which was greatly impaired. Was unable to walk or stand when brought to the hospital.

September 27th. Had been somewhat noisy at times since previous record; without knowledge of where he was or how long he had been there; remem-

[5] Paralysies Toxiques, Thèse. Paris, 1886.

bered nothing of recent or past occurrences; sometimes unable to pass water without being catheterized; tenderness over posterior tibials about the same; unable to stand on feet.

October 7th. At this date could stand with assistance.

October 14th. Mental condition improving slowly; cried like a child and bewailed himself bitterly if left alone in bed with the screens around the bed. Was able to stand without assistance; tenderness over posterior tibials less pronounced.

October 20th. Walked about the ward with a cane.

October 30th. Walked without a cane, could stand easily with his eyes shut; mental condition clearer; patellar reflex still absent; electrical reaction of degeneration in both legs; grasps by manometer right = 86; left = 80.

November 8th. Was improving mentally and physically rapidly. Could walk well, even vigorously. Was anxious to go home and was discharged much relieved. I communicated with his employers and learned that he, the patient, had exhibited unusual stupidity, and inefficiency in his work for about three months before coming to the hospital; that he had lost strength in his feet and legs and been complaining of them for "a year or more;" that he gave up work the last day of August. Used "to drink hard" but not to intoxication. Duration of symptoms from beginning, twelve to fourteen months; of acute symptoms before entrance, seventeen days; in the hospital seven weeks and a half.

Case IV. *Alcoholic Neuritis.* A. H., aged thirty-three years, male, grocery and liquor business. Had hip disease, left hip, when four years old, but grew up to be a strong, vigorous man; no rheumatism; no venereal. Used to be a butcher, until six years ago when he took up his present occupation. Drank liquor moderately, until two years ago, when he began to drink hard, twenty-five or thirty glasses of all sorts of liquor in the course of the day. Had an attack similar to the present one eighteen months ago, from which he partially recovered, on leaving off alcohol partially. Subsequently began to drink again, kept himself in a boosy state most of the time, but was never too drunk to take care of himself. Up to thirteen weeks before coming to the hospital had been drinking especially hard, but since then has abstained entirely. Entered the hospital, November 1, 1887, as a private patient under Dr. Shattuck. Thirteen weeks before began to notice increased weakness in his legs, the hands also became weak and he had to give up work; a week later limbs became numb and felt asleep, but were acutely sensitive to the touch; for three or four weeks had had sharp, darting, corkscrew pains in the legs, and especially in the feet, but not such as to keep him from sleeping; these pains had been diminishing, and at entrance had assumed the character of occasional dull pain and a numb feeling; no pain in arms, except slight lameness in region of right elbow; eyesight good, but fifteen weeks ago saw double and vision was blurred for a week or two.

November 1st. Appetite good, sleeps pretty well; temperature 98.8°, pulse 104. Tongue clean, protrudes straight; pupils equal, reacting to light and accommodation; grasps weak, with manometer right = 35, left = 32; left leg three inches shorter than the right; weakness of extensors of both feet very marked; toe-drop on left foot; knee-jerks and plantar reflexes absent; tenderness on pressure over the course of all nerves of the arms and legs, but most pronounced over the posterior tibials; sensation diminished in legs and arms, but more marked in some areas, less noticeable on arms than on legs; perverted sensation on legs and feet, a touch on inner side of right foot referred once to left foot and again to right leg, a touch on right leg between knee and ankle referred to top of left foot. Romberg's symptom not tested on account of hip. Reaction of degeneration in legs.

November 10th. Improving slowly under galvanism (weak current), massage, quinine and arsenic. Present duration three and one-half months. Remains in the hospital, and will probably recover perfectly, perhaps in from four to six months.

Case V. *Alcoholic Neuritis.* K. S., aged thirty-eight, female, married, housework. Had "rheumatism" twice, facial erysipelas once. No syphilitic history. Had borne six children and had two miscarriages; youngest child eight years old. Acknowledged the habit of drinking "a little beer." Entered the hospital, November 15, 1886, Dr. Shattuck's service.

Subjective Symptoms. For a month had complained of great weakness, poor appetite, occasional dry cough. Any little unusual event worried or excited her unduly; lately when excited had experienced feeling of oppression about the heart. Sleep pretty good.

Objective Symptoms. Examination of thorax and abdomen negative result, except a good deal of tenderness in lower intercostal spaces on both sides of thorax. Tongue pale and flabby. Tongue, eyelids and hands tremulous. Pupillary reaction to light and accommodation present. Patellar reflex absent; plantar reflexes very active; slight diminution of sensation in legs; tenderness on pressure in right calf and over upper portion of both sciatics. Temperature 99.2°, pulse 104, respiration 24. Urine normal.

November 20th. Appetite and sleep pretty good, but mentally mildly confused. Got out of bed several times at night and wandered about aimlessly. Complaining of pains in the legs, and of a "crushed" feeling about the heart. Pulse small and somewhat accelerated.

November 24th. Complaining of stiffness in the knees, and much tenderness over the nerves of the legs was noticed.

November 27th. Marked tenderness over both sciatics and over posterior tibial nerves on both sides; slight diminution of sensation in areas over both legs, especially on right; loss of power in muscles which move right toes and foot, less on the left side. Knee-jerks still absent. No tenderness in the arms. Had delusions that she went to various places during the day, at night got out of bed and wandered aimlessly about.

December 4th. Quite emotional; no memory, delusions as to time and space.

December 7th. Still great tenderness over nerves in the legs, especially posteriorly; knee-jerks still absent, and plantar reflexes active. Tongue brown, dry and heavily coated; pulse 120; temperature 100°. Thorax and abdomen were examined without finding anything abnormal.

December 10th. Growing weaker; attempts at speech for the most part unintelligible mutterings. Sordes on teeth and lips.

December 12th. Failed rapidly since the last record; nearly comatose, respiration very rapid, swallowing almost nothing; when moved in bed seems to suffer great pain. Death.

Duration in hospital twenty-five days; from beginning about two months. An autopsy could not be obtained; about one and one-half inches of the upper part of the posterior tibial nerve was given Dr. W. W. Gannett for microscopical examination, but he failed to find any signs of neuritis in that piece.

CASE VI. *Alcoholic Neuritis with previous Phthisis.* E. F., aged thirty-one years, female, married, housewife. No history of alcoholic habits. Entered the hospital, general service, July 21, 1885, on account of phthisis, for which she was treated. One sister died of "consumption." She reported having had "rheumatic" pains a year previously, and confessed to drinking beer. Her illness began four months before admission to the hospital with a "cold." Record says: "for past three weeks has noticed that she sees double at times. At first the right eye turned out somewhat and the eyelid drooped a little. . . . Pains all over her, especially in the legs."

August 4th. Pains in the legs less, general condition improved.

August 13th. "Rheumatic" pains now chiefly in the feet.

August 17th. Feet strongly extended and painful. Gastrocnemii painful and spasmodically contracted and twitching.

August 31st. Less pain in feet, but still strongly extended.

September 2d. Splints applied to feet.

September 4th. Patient could move feet freely; slight sensation of pins and needles in the legs. Sat up.

September 16th. Could move the feet freely, but still complained of the pin-and-needle sensation, pains in legs and feet much better. The signs in the lungs had increased in extent, and the patient constantly lost flesh and grew weaker. She was transferred to the "nervous service," in charge of Dr. Prince, and the record of this service says: "For the past four weeks has been unable to walk; complains of numbness in the legs and a feeling of pins and needles in the toes; legs and arms have been very painful on pressure for six weeks. Some tenderness now present over the course of the anterior crural and sciatic nerves; general weakness of the legs; no anæsthesia of the legs; patellar reflex absent.

September 26th. Marked choreic movements of toes reported as coming on at intervals of an hour or two and lasting a few minutes. Right tibialis anticus responded to only the strongest faradic current; electrical excitability with faradic current much diminished in both calves, and the same true of the extensors of the thighs; other muscles were not tested; electrical sensibility of the skin diminished.

The pulmonary signs pursued a progressive course; the patient failed and died November 17th. The autopsy gave: tuberculosis of lungs (chronic), tubercular ulcer of the intestine, fatty infiltration of the liver. Dr. W. W. Gannett, who made the autopsy, removed the ischiatic nerve of the left leg from a little below the middle of the thigh, together with its two primary branches, down nearly to the ankle, hardened portions in osmic acid and examined them microscopically, but no evidence of neuritis or other lesion was discovered.

CASE VII. *Alcoholic Neuritis with Phthisis.* E. W., aged thirty-two years, female, housewife. Was brought to the hospital, October 18th, to Dr. G. H. Lyman's service, in a delirious condition, and unable to give an account of herself. From the husband, the following points were subsequently obtained: One sister died of phthisis; had been married seven years; never pregnant, catamenia very irregular and scanty, but painless. For three or four years, patient had been much troubled with vomiting, and this had increased markedly in the previous six months. For about three years, had been subject to so-called hysterical attacks, lasting a few hours, during which time her mind was much confused. For three weeks, had vomited much less; fell into a state of semi-unconsciousness two weeks before, from which she had not been aroused. Tongue dry, brown, and parched; pulse 132; abundant fine, moist râles over both backs, most marked at right apex, where there was dulness, broncho-vesicular breathing at both apices. Urine and fæces passed involuntarily. Pupils equal, reacting to light; no strabismus. Feet held in position of equino-varus; loss of power in extensors, and muscles of calf of leg flabby, patella tendon reflex absent, tenderness on pressure over nerve trunks of legs and thighs; sensation diminished over both legs. Weakness of extensors of forearms, with tendency to wrist-drop.

October 24th. Pulse 148, respiration 48. Patient's pulse and respiration became more rapid, and she died October 26th.

An autopsy by Dr. Gannett gave, as a pathological diagnosis: Chronic adhesive pleurisy; fatty infiltration; chronic tubercular broncho-pneumonia of liver; tuberculosis of spleen; tubercular ulceration of intestine; infantile uterus, small ovaries. The brain and cord were removed for examination. The peripheral nerves were not examined.

The husband, upon being further questioned, admitted that his wife took stimulants by physicians' orders, but never, to his knowledge, to excess. It was also subsequently learned from the physicians in charge before the patient entered the hospital (Drs. Doe and Breck), that a diagnosis of alcoholism had been made early in the summer; that the patient had been noisy and troublesome at times, but there had been no signs of tuberculosis, and no paralysis as late as the end of September.

CASE VIII. *Alcoholic Neuritis, with Nephritis.* C. S., aged thirty-three years, female, married, a housewife. Decided alcoholic history. Unable to walk for a week before admission to the hospital, September 14, 1885, under Dr. Prince. When seen, complained of loss of power in the legs, and was unable to stand; also of a feeling of numbness in the legs. Had to lift the legs to cross them. Patella tendon reflex absent. Spots of incomplete anæsthesia and analgesia on the legs, which became more extensive and more pronounced a few days later. Pain and tenderness over nerve-trunks and muscles in legs, but not in arms; also over muscles of abdomen, chest, and back. Reaction of degeneration in muscles of legs.

October 20th. Knee-jerk still absent, but tenderness over the nerve-trunks of legs little noticeable.

November 12th. She had improved so far as to be able to walk a short distance, and was discharged, relieved, at her own request. Course, two months.

Case IX. *Alcoholic Neuritis — Nephritis.* F. M., aged forty years, female, widow, dress-maker. Had always good health. Borne four children, and had as many miscarriages. No syphilitic history obtained. Entered the hospital, November 16, 1886, Dr. Shattuck's service.

Subjective Symptoms. For two months, had been losing appetite and strength, smell of cooking causing nausea. Had felt nervous and "fidgetty," and a strong craving for beer. Said that she had lost more flesh than she could "afford to." Gave up work three weeks before admission.

Objective Symptoms. Well developed, rather corpulent. Tongue red and glazed. Decided tremor of tongue, less of the extended hands. No tenderness or impairment of sensation over the arms. Great sensitiveness over the nerve-trunks in the calves, and in front of the thighs. Below the lower third of the thigh, considerable hyperæsthesia of the skin, sensation perverted; and, in lower portions, tactile sensibility impaired in areas. Patellar reflex absent. Unable to move toes of left foot, and those of right but slightly.

Examination of thorax and abdomen. Negative.

Urine. Turbid, alkaline, albumen; sediment, pus, squamous epithelium, numerous hyaline casts. Temperature 97.4°, pulse 124, respiration 24.

November 19th. Grew steadily worse since record. Slept little, delirium of a muttering type, stupor, at times somewhat noisy. Pulse rapid and small, temperature subnormal.

November 22d. Stupor had increased, gradually deepening, interrupted by occasional delirium. Pulse had continued rapid and almost imperceptible at the wrist; respirations were shallow and jerky; temperature always subnormal. Patient swallowed pretty well till just before death, which occurred on this date.

Duration. Six days in the hospital; nine weeks from the time she began to feel sick.

Autopsy by Dr. Gannett. Chronic adhesive pleurisy; injection of kidneys; chronic salpingitis; chronic pelvic peritonitis. Right ischiatic nerve removed, hardened for twenty-four hours in a one per cent. solution of osmic acid, and examined in glycerine. It showed extensive destruction of axis cylinders, and loss of white substance of Schwann.

Case X. *Multiple Neuritis. Alcohol and Phthisis not present; No Syphilitic History, though undoubtedly frequently exposed to infection; Toxic Influences could not be ascertained as present, or as having been active; Epileptic until two years before coming under observation; No Rheumatic History; No History of Exposure to Cold or Fatigue.* T. H., aged forty-five, female, widow, nurse. Entered the hospital, April 6, 1887, Dr. Shattuck's service.

Subjective Symptoms. Three months before, began to have a feeling of numbness in the fingers of the right hand (Dr. J. J. Putnam's "numb fingers"). This extended up the arm, and then up the other arm, and both feet and legs were affected in the same manner. Since five weeks, had not been able to walk without assistance. She said when she stood, it felt as though she were standing on pins and needles. Could not hold anything in her hands without watching it. During the first part of attack, could not see to read; subsequently, as well as usual; at one time, had difficulty in swallowing, but that passed away. Complained of cramps in feet and legs, and of coldness of extremities.

Objective Symptoms. Great tenderness on pressure over all the affected parts, but greater over nerve-trunks in the left leg and arm than in right; sensation in hands and arms, in feet, legs, and thighs much impaired, considerable pressure with the finger not felt, but a slight prick was felt immediately. Patellar reflex entirely absent; both grasps extremely weak; could not stand without assistance, but by leaning on a chair-back walked very slowly moving the feet a few inches at each step. Pupils responded to light and to accomodation. General health was pretty good, temperature and pulse normal.

April 16th. Complaining of pain in the limbs, but less severe. Sitting up daily for a time. Pain relieved by friction with hot olive oil; also had massage and weak galvanic current.

April 26th. Was able to walk a short distance without assistance. Still complained of slight pains and of vague disagreeable sensations in the legs and feet. Blisters were applied over the course of the nerve-trunks.

May 6th. Steady improvement since last record, and had been out walking in the yard a few times. The day before returned from the yard feeling cold, and went to bed. Shortly after had an epileptic convulsion followed by two others.

May 16th. No return of the convulsions, continued to improve, and was transferred to St. Luke's Home, from which she was discharged, June 7th, "much relieved." She has since been heard of as pursuing her usual avocations. Duration before entering the hospital three month; in the hospital, St. Luke's Home, two months; total five months.

Case XI. *Multiple Neuritis. No Cause Ascertained.* E. K., female, forty-six years old, married. Entered hospital, August 27, 1887. Service of Dr. T. M. Rotch, who was succeeded in charge by Dr. A. L. Mason, by whom patient was transferred to Dr. Shattuck. Family history negative. Said she had an attack similar to the present at the age of seventeen years, following exposure to wet and cold, and had had "rheumatism" several times. She thinks the present attack due to exposure in her work as a washerwoman. She seems to be a very respectable person, and repeated careful questioning has failed to elicit an alcoholic history. She is a German; has been ten years in this country; occasionally but not regularly takes a small amount of beer. Present attack began three weeks before entrance, with pains in ankles, knees, and hands, some swelling of ankles, chilly sensations. Appetite poor.

Physical examination. Well developed and nourished. Heart and lungs negative. Tenderness on pressure over nerves of body, limbs, and head. Sensation diminished. Atropy and marked loss of power in the arms and legs. Patellar reflexes absent.

Temperature 100.2°, pulse 124, respiration 30. Urine pale, acid 1011, no albumen.

September 5th. Atrophy more marked. Tenderness over nerves still persists.

September 23th. Legs flexed on thighs constantly; considerable pain on attempting extension. Appetite good.

September 29th. Grasps very weak. Legs cannot be straightened.

October 6th. Flexion more marked; has been sitting up in chair daily since last note.

October 12th. Legs have been straightened by means of ham splints; and massage daily.

October 19th. Can move legs freely, but cannot flex and extend feet. Is just able to stand, but cannot walk.

November 3d. Moves legs a little more freely, but is unable to stand. Reaction of degeneration quite marked in arms and legs.

November 8th. Patient was transferred to Dr. Shattuck's service. Physical examination revealed the following: Marked loss of power in muscles of forearms and hands; grasps extremely weak, (with dynamometer right = 10, left = 13). Both legs weak, and moved with great difficulty. Complete toe-drop on both sides. Plantar and patellar reflexes absent. Some atrophy of muscles of forearms and legs; right calf measures 10 inches in circumference, left 10¾ inches. Sensation much diminished over forearms, hands, legs, and feet, more marked in some areas than in others. Tenderness over peripheral nerves most marked in forearms and legs.

This patient is still in the hospital, and has been there now two months and a half. Her attention was first attracted to her condition three weeks before admission, making the total duration about fourteen weeks. She improved at first somewhat, and then relapsed. She is again improving slowly but steadily under galvanism, massage, citrate of iron and quinine, and generous diet. She will probably recover, though it may take from six months to a year. I have been unable to discover any toxic influence as a cause, and I am inclined to believe her statements with reference to alcohol.

THE ENDOSCOPIC INSTRUMENTS OF JOSEPH LEITER OF VIENNA AND THE PRESENT DEVELOPMENT OF ENDOSCOPY.[1]

BY OTIS K. NEWELL, M.D.
Assistant Demonstrator of Anatomy at the Harvard Medical School.

WHOEVER has had much experience with the endoscope, especially in examination of the bladder, knows with what difficulty a well-illuminated field is maintained, since every deviation of the mirror reflected light, by hand-movement or otherwise, leaves the field in darkness, and the examination must be discontinued until the light is returned. This want of a permanent and easily maintained illumination has undoubtedly been what has kept the practice and good results of endoscopy so much in the background.

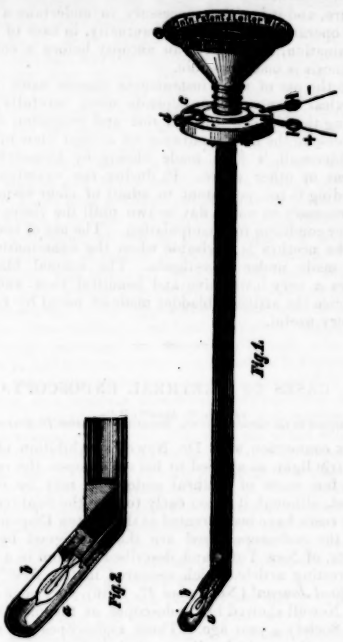
One year ago, I had the pleasure of showing before the Suffolk District Society my own endoscopic tubes. Since that time the improvement in methods of illumination has been so great, that from the practical standpoint there is scarcely any comparison. This has all been brought about by the successful application of the electric light to endoscopic illumination through the efforts of Joseph Leiter, the celebrated instrument-maker of Vienna.

About twenty-five years ago Bruck, of Breslau, had produced an electrical illuminating apparatus for examination of the mouth and bladder. The light was from a platinum wire, and in order to overcome the intense heat produced, a coil of pipe for circulation of cold water about the lamp was necessary. This instrument, although it could be used, was never of very practical application.

[1] Read before the Massachusetts Medical Society, Suffolk District, October 29, 1887.

In 1877–78, Dr. Nitze, of Vienna, devised, and had made by Leiter, similar endoscopic instruments, but their complexity and high cost stood in the way of their extended use either for instruction or practical purposes. Urged by Nitze to further continue experimental work with these instruments, Leiter, by his indefatigable energy and admirable devotion to the not very remunerative work, has at last succeeded in perfecting all that seems necessary to the further and rapid development of endoscopy.

In 1883, I had the pleasure of visiting the International Electrical Exhibition at Vienna, and I afterwards learned that it was there that Leiter's attention became directed to the carbon filament light, and the problem of endoscopic illumination seemed then to be solved. Professor Dittel, who had already obtained some good results with the previous instruments in examination of the bladder, gave his strong coöperation to Leiter, and towards the end of 1886 a practical endoscope for this purpose, cystoscope, was produced. In 1887, an electro-reflector for the illumination of plain endoscopic tubes was finished, and as it was to be applied to all tubes for examination of any of the body cavities, Professor Dittel suggested for it the name of "Panelectroscope." The gastroscope was made under the the direction of Professor Miculicz, who has had the most extended experience with this instrument. It corresponds closely to the cystoscope in construction differing only in a double reflection of the picture in its optical arrangement, and in having in addition a double air current through its tubes, one for cooling the lamp and the other to distend the stomach.



In March of 1887, Professor Dittel showed the instruments before the Imperial Medical Society of Vienna, and the thanks of the society were voted to Mr. Leiter for the self-sacrifice and zeal which he had shown in bringing his efforts to a successful termination.

In detailing the construction of these instruments I can do no better than to quote as much as possible from a description by my friend, Dr. Alexander Brenner, of Vienna, published in the *Centratblatt für Chirurgie*, 1887, No. 25.

THE CYSTOSCOPE.

The body of this catheter-shaped instrument is formed by two thin metallic tubes, one within the other, separated by an intermediate layer of non-conducting material. These two tubes are connected with the battery. The lumen at the outer end of the tubes is closed by an ivory plate into which two cylindrical metal capsules are sunk. The capsules are connected one with the inner, one with the outer tubes for conduction. If now a small incandescent lamp is united with the tubes at their lower end, and the capsules are connected above to the wires from the the battery, the current circulates through the carbon filament, and with a strength of about three to four volts brings it to a white heat. The intensity of the light when run by the battery and fluid as made by Leiter (Fluid = 336 gms. pure chromic acid; 250 gms. sulphuric acid; 2000 gms. water), remains for hours equal. The lamps last about thirty hours, and when burned out can be replaced.

In order to be introduced into the bladder, and for its best protection, the lamp is covered by a metallic capsule, the "lamp-house," which screws down over

it. A thick crystal glass window is placed in the side of the lamp-house, and through it the rays of light stream out into the bladder-cavity. The capsule forms a water-tight joint about the lamp, and excludes possibility of injury to the bladder in case the lamp should break. At the same time it admits of the lights being held under water whereby the heat distributed upon its relatively large surface is rapidly conducted away by the fluid in the bladder, the instrument being always used in a bladder filled with water to which some antiseptic has been added. The water circuit for cooling is thus unnecessary. A circuit-breaker is attached to the outer end of the instrument, the "Pavillion," so that the light may be first started after the instrument is within the bladder. It consists of a metal switch which is connected with the inner tube, and can be moved from an ivory isolating plate on to the ring in connection with the outer tube and battery, and the current thus conducted to the inner tube and lamp. When the switch is pushed back upon the isolating plate the current is broken.

In a bladder distended with from six to eight ounces of fluid, the instrument can be kept for an hour without any appreciable change in the temperature of the surrounding fluid being felt, and without causing any pain to the patient from the instrument becoming warm. The cystoscope is introduced with the circuit open. After introduction the current is closed and the bladder illuminated. Before withdrawing the instrument the circuit is again opened. Figure 6 shows the cystoscope in an artificial bladder.

The battery for these lights must be so arranged

FIG 6.

as to admit of regulating the current strength in order that the lights be not ruined by too high tension. Such a battery is the one made by Leiter in which the elements are raised and lowered on a supporting screw-rod. The plates are lowered into the fluid until the lamp glows with sufficient brilliancy. Any battery with which the current strength can be regulated suffices, and the same may be accomplished by the use of a rheostat.

The optical part of these instruments is similar to the already familiar Nitze instrument, the lenses focusing for a large field with diminished size of object.

My endoscopic tubes as figured in this JOURNAL of November 11, 1886, and above, are now made by Codman & Shurtleff, attachable to the panelectroscope. With them, excepting the interposition of the fenestrum, the object is seen directly, but must be gone over in detail. Through the open tubes *instrumentation within the bladder* is admitted, and small pieces of tumor or other objects can thus be removed for examination. In this connection it is perhaps interesting to quote from my paper of last year Professor Grünfeld's statement that "the introduction of instruments into the (male) urinary bladder under control of the endoscope, as well as their application there, was, for apparent reasons, not to be thought of." The anterior bladder-wall is only to be seen by the Leiter-Dittel cystoscope with mirror reflection.

FIG. 4.

The construction of the panelectroscope is made apparent by the figure. The electric lamp is moved up or down by screw-adjustment so that the rays of light may be reflected from the fixed mirror *a* into the tube in the manner indicated by the lines in the

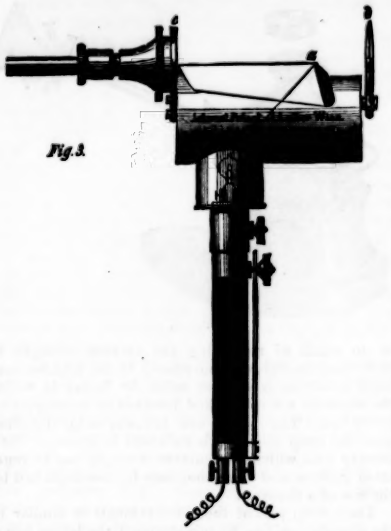


Fig. 3.

figure. Over the top of the mirror a view of the field is obtained, and instruments may be passed down into the tubes. A lens may be inserted at *b* for myopic or hypermetropic individuals.

FIG. 5.

The importance of these instruments lies in the fact that from their simple construction and practicality a closer knowledge of the physiological and pathological conditions of the bladder may be readily obtained.

I have already had the pleasure of twice diagnosing a tumor of the bladder, once for Dr. M. H. Richardson, and again for Dr. C. B. Porter, both of the Massachusetts General Hospital. It is no exaggeration to say that the growth could be seen as plainly as a section under the microscope, and there seems to be now nothing in the way of bringing these hitherto obscure cases to rational and intelligent treatment.

Who is not familiar with that type of intractable bladder disease, where with symptoms of stone, tumor, foreign body, tuberculosis, or other cause of cystitis, all manner of examination still fails to reveal its true nature, and it is either necessary to undertake a serious operative measure, or, eventually, in case of fatal termination, to plead for an autopsy before a correct diagnosis is made possible.

In the use of these instruments, success aside from practical manipulation depends upon carefully preparing the bladder through rest and irrigation so as to remove the only hindrance to a clear view of the bladder-wall, a fluid made cloudy by hæmorrhage, mucus or other cause. If, during the examination, bleeding is too persistent to admit of clear vision, it is necessary to wait a day or two until the viscus is in better condition for manipulation. The use of cocaine in the urethra is advisable when the examination is not made under anæsthesia. The normal bladder offers a very instructive and beautiful view, and for practice the artificial bladder made of metal by Leiter is very useful.

CASES OF URETHRAL ENDOSCOPY.[1]

BY G. W. ALLEN, M.D.,
Surgeon in the Genito-Urinary Department, Boston Dispensary.

IN connection with Dr. Newell's exhibition of the electric light, as applied to his endoscopes, the report of a few cases of urethral endoscopy may be of interest, although it is too early to give the final results. The cases have been treated at the Boston Dispensary, and the endoscopes used are those designed by Dr. Klotz, of New York, and described by him in a very interesting article, which appeared in the *New York Medical Journal* (November 27, 1886), very soon after Dr. Newell showed his endoscopes at the meeting of this Society a year ago. These endoscopes are made of coin-silver, which allows of their being very thin and light, and are less affected by the solutions used in treatment. To the distal end is attached a disc, faced with unpolished gutta-percha, to prevent the reflection of light, and large enough to keep a redundant prepuce out of the way when the endoscope is pushed in deeply.

The light used in these cases is furnished by an Argand gas-burner, intensified by means of a lens, and reflected into the urethra from a head-mirror. The patients have been examined standing. In treatment, nitrate of silver alone has thus far been used, in solutions of one, two, and three per cent., applied by means of a cotton tampon on the end of a wire. I have not yet examined the membranous or prostatic urethra. Of the various appearances described by Dr. Klotz, I have yet seen only congestion of different degrees, with an occasional granular appearance, œdematous swelling of the mucous membrane, rigidity of the urethral walls at the seat of strictures of large calibre, and, in one case, dark spots, which probably showed a higher degree of inflammation about the lacunæ of Morgagni; also, occasionally, dilated capillaries in the bulbous portion.

The results here reported are by no means remarkable; but, considering the short time covered by the treatment, the lack of experience, and an imperfect light, they seem encouraging enough to warrant a continuance of the practice, with such improvements in method as may be developed. The patients have all expressed themselves as feeling better than under any

[1] Read before the Massachusetts Medical Society, Suffolk District, October 29, 1887.

other treatment, even when the improvement has apparently been slow.

Case I. S. R., aged twenty-three, had gonorrhœa five years ago, and has had an almost constant urethral discharge ever since. He has been treated quite steadily for nearly two years with injections, irrigations, sounds, etc. On August 4th, he was examined with the endoscope. The mucous membrane of the urethra was found to be congested, especially in the bulbous portion, where a network of capillary vessels was visible, and in the middle of the spongy portion, where there were granular patches of a deep-red color, and where a marked rigidity of the mucous membrane was noticeable at two or three points. A one per cent. solution of nitrate of silver was applied. This treatment was repeated twice a week until August 30th, with steady diminution of the discharge, and improvement in the appearance of the mucous membrane; but suddenly, without apparent cause, the discharge increased in amount, although thin and watery, and treatment was suspended until September 20th, when the endoscope showed considerable congestion, less, however, than when first examined. After this, the treatment was less frequent and regular, but improvement continued. The strength of the solution applied was increased to two, and later, to three per ent.

October 27th. What little discharge there is, is of the sticky nature of prostatic secretion. Endoscopic examination shows diminished congestion throughout. In the middle portion, the mucous membrane is still quite rigid, although much less so than at first. In place of the granular patches, reddish-brown spots, the size of a large pin-head, are to be seen.

Case II. C. S., aged thirty-three, had gonorrhœa eight years ago, and again three years ago; since this last attack, there has been a constant discharge. Within the last year, he has had two attacks of inflammation at the neck of the bladder, the last one, in June, very severe; and, on August 23d, when the endoscope was first used, the effects were still noticeable in a slightly increased frequency of, and straining after, micturition. The mucous membrane, at the first examination, appeared deeply congested, especially in the bulbous portion, and the anterior half of the penile urethra; in the middle portion, it was swollen, granular, and rigid. It was touched with a one per cent. silver solution, which was subsequently changed, as in the first case, to two, and then to three per cent. This treatment was continued six weeks, about twice a week, with relief of the urinary symptoms, and gradual improvement in the appearance of the mucous membrane.

October 6th. The patient was examined for stricture, and one was detected with a bougie à boule No. 31 (French scale), but it easily admitted a 33. The size of this stricture, on June 7th, was 27, and no instrument larger than 27 had been passed through it since, or at that time.

Improvement continued, although very slow, the meatus being sometimes perfectly dry, and sometimes showing a slight discharge. A relapse of the urinary symptoms was relieved by a deep injection of nitrate of silver, and at present, the mucous membrane, although considerably congested for the space of about two inches in the middle portion, no longer has the livid hue which it had at first, and the rigidity of the urethral walls is very much diminished.

Case III. F. C., aged twenty-eight, first had gonorrhœa ten years ago, has had many fresh attacks and exacerbations since, and has had a constant discharge for more than a year.

August 25th. The endoscope revealed a congested condition, especially of the middle portion of the urethra, which was painted with a one per cent. solution of nitrate of silver, and, five days later, already looked better.

September 3d. The patient reported himself as entirely free from discharge for the first time in a year.

October 22d. He returned with a slight discharge. The condition of the mucous membrane was about the same as when last seen. It was touched with a two per cent. silver solution.

Case IV. E. M., aged nineteen, has had a chronic urethral discharge for nearly a year. The urethra was examined with the endoscope, September 13th, and the mucous membrane found to be quite deeply congested in the middle portion, where it was also rigid and sensitive to the touch. The one per cent. solution was applied, and, at the third visit, the discharge had stopped, the local condition was found improved, and the patient said he was better than he had been for six months. The improvement has not continued uninterrupted. At times, generally after nocturnal emissions or other sexual excitement, there has been a little discharge, and a slightly increased degree of congestion has been noted, but, on the whole, he is doing well. At present, the discharge is almost imperceptible, and the urethra looks much healthier than it did six weeks ago.

Case V. W. C., aged nineteen, had gonorrhœa nine months ago, but has had no discharge for four months. He has a stricture, which has been dilated to 28.

September 15th. He complained only of vague sensations in the penis, and the endoscope showed a moderate degree of congestion at a point just anterior to the bulbous portion. This was touched with the silver solution, and the treatment repeated every four or five days, the endoscope showing a gradual improvement in the local condition. The patient says he is better than at any time since the beginning of his trouble. The mucous membrane now appears almost normal, and he is practically well.

REPORT ON DERMATOLOGY.

BY G. H. TILDEN, M.D.,
Physician to Department for Diseases of the Skin, Boston City Hospital; Instructor in the Boston Polyclinic.

MYCOSIS FONGOIDE.

The evidence collected during the past two years with regard to mycosis fongoide has gone to show [1] that there are no specific microörganisms which bear an etiological relation to the development of its cutaneous lesions, and that the streptococci mentioned by Rindfleisch and Hammer in this connection, are in reality those belonging to septicæmic processes, while those described by Auspitz and his assistants are merely accidental and such as might be found in any so favorable a culture medium as fungous tumors, deprived of epidermis.

[1] Vide Dermatological Report in this Journal of May 12, 1887.

Kühne[2] has recently given the results of his examination of the pathological specimens furnished by a victim of this disease. The case presented the usual clinical picture and fatal termination of mycosis fongoide. Death took place with symptoms of general septicæmia and after partial gangrenous destruction of several of the cutaneous tumors.

Two points of interest were shown by the microscopic examination of sections made from the cutaneous lesions:

(1) The walls of the contained bloodvessels were normal in structure and were not invaded by the new growth, and composed of embryonic cells, as is the case in true sarcoma.

(2) In no section made from pathological cutaneous tissues still covered by epidermis, were to be found any microörganisms whatever.

CUTANEOUS PIGMENT.[3]

If the skin of a white man be transplanted to the body of a negro, the white and transplanted portion of skin becomes as black as the skin of the negro. Black skin, on the other hand, when transplanted to a white man, loses its pigment and becomes white. The cutaneous pigment reaches the epidermis by means of the prolongations of cells which lie at the junction of the rete Malpighi and cutis, and which deliver their pigment granules to the cells of the epidermis. These pigment-carrying cells and their prolongations play an important part also in the nutrition of the epidermis. For, as long as the network formed by the pigment cells is not present or undeveloped, so long do the epithelial cells of transplanted skin present all the signs of poor and insufficient nutrition. The epithelial layer is thin, the nuclei of its cells do not readily absorb artificial coloring matter and in the cells themselves are to be found vacuoles and fat granules. As soon, however, as the pigment cells make their appearance, there ensue numerous karyokinetic[4] figures.

In white skins also, these branched cells exist, but they and more especially the network formed by their prolongations, are difficult of demonstration on account of their deficiency in pigment as compared with the same cells in the skin of the negro.

Kölliker confirms the statements according to which no pigment is formed in the epidermis, but is conveyed to it by means of the immigration of pigmented and wandering cells from the neighboring connective tissue. In human hair; in the "velvet" of the antlers of the stag, when in a state of development; in the feather germs of the hen and in the epidermis of the dromedary and gorilla, this condition of things is most easily detected and demonstrated. The branched and pigment-carrying cells as they insinuate their prolongations between the epidermal cells supply the latter with pigment. The horny cells of the epidermis are usually uncolored on account of the small amount of pigment contained in the epidermal structures. Sometimes, however, they contain a diffused pigment or else granules of pigment; as may be seen in dark hairs, in the nails of the enthropoid apes, and in the horny layer of the skin of the gorilla and of the whale. In the skin of the negro and in the pigmented epidermis of the Caucasian race, v. Kölliker was unable to find branched pigment cells, but he did find often in such cases, numerous, small, rounded and spindle-shaped pigment cells in the outermost layers of the cutis, which pigment cells also recurred among the deepest layers of the epidermal cells.

[4] Karyokinetic figures are lines and figures which appear in the nuclei of epidermal cells while they are in a process of division and multiplication. Their presence indicates the existence of cell activity and life.

IMPETIGO, FURUNCULOSIS AND SYCOSIS.

At a meeting of the Medical Society of Wiesbaden, Dr. Max Bockhart[5] delivered a lecture upon this subject. With regard to the existence of impetigo as a distinct disease there has been difference of opinion. Erasmus Wilson was the first to give a definite form to the conception of impetigo, by saying that he regarded as impetigo only those pustular eruptions which appeared upon the skin as pustules from the beginning, and which were not developed from pre-existing nodules or vesicles. Hebra, on the other hand, denied the existence of impetigo as a distinct disease (with the exception of impetigo contagiosa, so-called, and impetigo herpetiformis), and was of the opinion that impetiginous pustules were always a secondary development from some preëxisting form of cutaneous inflammatory process.

So-called impetigo simplex is a pustular eruption, which begins as such and the pustules of which it is composed, are formed quickly and undergo but little subsequent change in the way of development. As a rule they are small in size, varying from that of the head of a pin to that of a pea. If punctured and emptied of their contents they quickly refill, remain for days unchanged, and gradually dry to yellowish crusts, which, as a rule, are slow in falling off and which leave behind no scar. Oftentimes these pustules are pierced by a hair and usually the skin in their neighborhood remains unchanged, or is but slightly reddened. It is seldom that itching forms a prominent symptom, being usually absent, or if present but slight in amount. These lesions may develop upon any part of the body and, as a rule, they are scattered over the skin in variable quantities, their most common seat being the extremities and particularly the nates. Sometimes they may be seen upon the mucous membrane of the lips and front of the mouth, in which situation they result in the formation of rounded and superficial erosions. Occasionally the eruption may be almost universal. In cases where the disease attacks hairy portions of the body, such as the bearded parts of the face, the clinical picture presented is not that of impetigo but that of sycosis non-parisitica. The affection may be acute or chronic and the eruption appears in successive crops. Often during the course of the disease there are formed one or several furuncles in the midst of the impetiginous eruption, and even after the disappearance of this eruption it is not uncommon to see furuncles subsequently develop. Besides this form of simple and idiopathic impetigo there occurs a variety of the eruption, called by the writer accidental, and which appears only during the course, and as a complication, of various inflammatory and pruriginous cutaneous diseases, such as eczema, scabies, prurigo, etc. This latter form of eruption, however, is the same in course and appearances as the former.

With regard to the etiology of this disease, the

[5] Monatsheft. f. Prakt. Derm., 1887, No. 10.

writer has examined ten cases of idiopathic impetigo, and twelve of the so-called accidental variety. From each one of these twenty-two cases was taken the purulent contents of unruptured pustules, which was examined both microscopically and by means of culture experiments. The microörganisms thus obtained were propagated from generation to generation in various media. In every one of the specimens of pus thus examined were found the same kind of cocci, namely, small staphylococci of from 0.5μ to 0.8μ diameter. They were found both free and contained in the pus cells, and existed occasionally as monococci, more often as diplococci, and were sometimes arranged in groups. Their number was variable and cultivation showed them to be made up entirely of two varieties, namely staphylococcus pyogenes aureus and albus. These two varieties are to be distinguished one from the other, merely by the different colors of their colonies when produced in pure cultivations. They are the same microörganisms which are found in connection with acute purulent processes in other tissues than those of the skin, such as felon, acute infectious osteomyelitis, ulcerative endocarditis, acute abscesses and phlegmonous inflammation of the subcutaneous connective tissue. In the lesions of impetigo both varieties of cocci were usually found combined in the same pustule, but occasionally only one or the other would be present. In the contents of the unruptured vesicles of so-called impetigo facei contagiosa, the writer has never found either the staphylococcus aureus or albus. Examination of the furuncles, which so often appear during the course of impetigo, showed that they as well as the impetiginous pustules, contained both staphylococcus aureus and albus.

The idea naturally suggests itself that these microorganisms are the cause of both the above forms of cutaneous lesion, and in order to determine this point by other than clinical evidence, Bockhart made two innoculations upon himself with pure cultures mixed, of staphylococcus aureus and albus, in the sixth and tenth generations. The innoculations were made upon the arm, the skin of which had been previously disinfected and slightly scratched with a scalpel. In each instance there ensued in from twelve to fourteen hours after innoculation, the development of numerous, separate and typical pustules of impetigo. The experimenter saw many of these pustules during the process of formation, and is able to confirm the statement of Wilson with regard to them, namely, that they appear as pustules from the beginning and do not materially increase in size after having once been formed. After an existence of eight days most of these pustules had dried up and the crusts had fallen off without leaving behind any scar. Two of them, however, became transformed into painful furuncles, which lasted for two weeks or more. The pus taken from these pustules and furuncles was found by examination and by cultivation experiments to contain both staphylococcus aureus and albus.

In order to determine in what manner these cocci were arranged in the cutaneous tissues and in what way they found an entrance into the skin, the author caused to be excised from his arm a piece of skin upon which were situated three pustules. From microscopical examination of sections made from this piece of skin and from the innoculation and cultivation experiments mentioned above, Bockhart draws the following conclusions: The pustule peculiar to impetigo is caused by the entrance into the epidermal tissues of the staphylococcus pyogenes aureus and albus. The openings through which these microörganisms find entrance, are: (1) The openings of the ducts of the sweat glands, (2) the mouths of the hair follicles and the ducts of the sebaceous glands, and (3) regions of the skin which by reason of insult are deprived of the horny layer of the epidermis. So soon as these pyogenetic cocci have been introduced into the skin they propagate and develop in the wall of the excretory duct of a sweat gland and in the Malpighian layer of cells immediately around its mouth; or in the outer root-sheath of a hair follicle, and in the excretory duct of a sebaceous gland and its neighborhood; or else in any portion of the epidermis which has been deprived of its horny layer. They multiply with great rapidity and set up in the surrounding tissues an acute and essentially purulent inflammation, the activity of which is shown by the rapid formation of pustules. The process, however, does not usually spread beyond the epidermis, and the pustule represents its ordinary culmination. Furuncles, however, may be developed from pustules, which are situated over a hair follicle, or over the duct of a sweat gland by reason of the propagation of these pyogenetic microörganisms into these glandular tubes and sacks, and the consequent excitement of peri-glandular inflammation. The so-called "core" of the boil is modelled by the glandular and follicular sheaths, and consists of masses of cocci and necrosed tissue.

Not only in these two varieties of cutaneous lesions did the author find the staphylococcus aureus and albus constantly present, but also in the lesions of so-called sycosis non-parisitica. Five examples of this disease were examined, and in every case the nodules, pustules, furuncles and abscesses peculiar to it were found to contain the staphylococcus aureus and albus separately or in combination. As a rule, sycosis of the upper lip is accompanied by chronic nasal catarrh and it is suggestive in this connection to note that the mucous discharge from the nose of one patient afflicted with sycosis was found to be swarming with these pyogenetic microörganisms. Clinically, however, sycosis differs from impetigo in two points: (1) That usually the pustules in sycosis are developed from preëxisting nodules, and (2) that in sycosis there are often developed large inflammatory swellings which may contain but little pus. In the opinion of the author these clinical differences are due to the peculiar structure of the regions of skin which are the seat of sycosis.

These pyogenetic microöganisms are among the most ubiquitous of all the pathogenetic bacteria. They have been found in wash water and in the swaddling clothes of infants. Bockhart detected them, both by microscopic examination and by the production of pure cultures upon gelatine, in the scrapings from the skin of three healthy persons out of eight examined, and under the nails of one individual out of six examined with reference to their presence. The experiments of the author seem, so far as they go, to fulfil the four conditions supposed to be necessary in order to establish the claim of any special microörganism to be considered as pathogenetic with regard to any special disease, namely:

(1) Their presence in every case of the disease.

(2) Their presence in sufficient quantity to account for the existing pathological condition.

(3) Their isolation and the production of their pure cultures upon some medium outside of the living organism.

(4) The reproduction of the disease in question by the innoculation of some healthy organism, with the pure cultures thus obtained.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

NOVEMBER 14, 1887. The President, DR. O. F. WADSWORTH in the chair.

DR. GEORGE B. SHATTUCK read a paper on

MULTIPLE NEURITIS.[1]

DR. S. G. WEBBER said that many of the cases reported to-night seem to be much milder than his own. Before the disease was recognized he had seen a few cases supposed to be temporary disease of the spinal column; and a few supposed to be locomoter ataxia, which may have belonged to this class; but making all possible allowance for unrecognized cases, there was in 1883 to 1884 a very great increase in the number of patients with the symptoms of neuritis, above the number previous to 1883. People drank beer and liquor before, and it is singular that there should be so many cases seen in so short a time with so few seen previously. Possibly there have been changes in the manufacture of beer that may account for it. In one respect the cases of the reader differ from most of those of the speaker. In his own there was a marked contraction and stiffness of the extremities, the legs being flexed on the thighs and the thighs on the abdomen. This contraction was not so marked in the arms. There seems also to have been less tenderness than in Dr. Webber's cases, at least it was not spoken of. In other respects the symptoms were about the same. Numbness was a marked symptom in some of the cases. The tenth case of Dr. Shattuck suggests lead poisoning, but if lead was not found in the urine after treatment with iodide of potassium, it was probably absent.

Inflammation of the muscles without neuritis needs to be diagnosticated from the changes caused by neuritis. Last year Dr. Jackson reported such a case and another case has been reported in the *Zeitschrift für Klinische Medicin*.

DR. C. F. FOLSOM said that he wished to call attention to cases of peripheral neuritis in which there were neither pain nor unusual tenderness on pressure, several of which he had lately seen. He supposed the lesion to be a sub-acute parenchymatous degeneration. If in the legs, the differential diagnosis between neuritis and posterior spinal sclerosis may be exceedingly difficult and sometimes for a while impossible.

He had also seen two cases ending in recovery, which involved the arms, where the conditions closely simulated those of anterior poliomyelitis. He believed that the favorable prognosis of the books, in the case of anterior poliomyelitis of adults is due to errors in diagnosis, multiple neuritis being mistaken for that disease.

[1] See page 523 of the Journal.

He asked whether the contraction mentioned by Dr. Webber might not be due to the posture of extreme flexure to avoid or diminish pain, and now controlled by splints, etc., more than formerly.

DR. J. J. PUTNAM inquired as to the symptoms in the case where autopsy showed nothing.

DR. SHATTUCK answered that in one case a small piece of nerve only, could be got. In this *piece* the result was negative.

Dr. J. J. PUTNAM spoke of the various different forms under which neuritis appears, some of them suggesting the presence of regular system-disease, like those met with in the affections of the spinal cord.

A recent writer upon the pathology of lead paralysis, reasoning in this manner, has suggested that the original cause of the neuritis may perhaps consist in a slight disorder of the ganglionic matter of the spinal cord, and that the reason the nerves become diseased at their peripheral extremity first, is that this part is farthest removed from their nutritive ganglionic centre.

Dr. Putnam spoke of a case formerly in the Massachusetts General Hospital, under the care of Dr. S. L. Abbott, where the symptoms tended unequally to show the presence of multiple neuritis of all four extremities. The case ended fatally. The peripheral nerves, unfortunately, were not examined, but a number of spots of softening were found in the brain, and the lateral columns of the spinal cord were sclerosed, and the bloodvessels greatly thickened.

It is quite probable that these latter changes were chronic, and in a measure independent of the neuritis, but some pathological connection may exist between them. This seems the more probable from the fact that the ganglionic cells were evidently more or less altered.

A large number of patients have been under observation at the out-patient's department of the Massachusetts Hospital, not presenting the atrophy and paralysis and marked sensory disorders seen in Dr. Shattuck's cases, but characterized by either persistent or recurrent numbness and prickling, with slight weakness, but without neural tenderness, having the same location as the severer symptoms.

DR. WEBBER spoke of the pathological changes which he had found in a case of neuritis. Even the specimens which were most extensively changed, contained some fine fibres which seemed unaffected. Perhaps these belonged to the sympathetic system. In other specimens taken nearer the trunk, one or two degenerated fibres were found, the others being apparently healthy or only very slightly changed.

DR. S. L. ABBOT said that the case referred to by Dr. Putnam was exceptional, as the autopsy showed several spots of softening in the brain. It has recently been emphatically stated that in general neuritis the brain is never affected. At the outset the patient complained mostly of pain in the feet which was decidedly lessened during the use of salicylate of soda. As the pain became more general, however, it was not controlled by this remedy. The progressive paralysis with corresponding defect of intelligence led to the impression that there was acute cerebral softening, a condition which was found at the autopsy.

DR. P. C. KNAPP said that, although the pathological processes in peripheral neuritis were not yet thoroughly understood, we must, nevertheless, rec-

ognize at least two processes. One was a true inflammation of the nerve, attended with hyperæmia, swelling, cell-infiltration, and hæmorrhages into the connective tissue; the other was a degenerative atrophy without inflammation, where the nerve-fibre atrophied, and was replaced by connective tissue. The clinical types of multiple neuritis were varied and numerous. We could distinguish at least three distinct classes; those due to toxic agents of a purely chemical nature, such as lead, arsenic, and alcohol; those due to some poison, chemical or organized, following infectious disease, as diphtheria, typhoid, or tuberculosis; and finally a class of apparently idiopathic cases, where a special infectious agent might be the cause of disease. In regard to Brissaud's theory concerning arsenical neuritis, it did not seem to him to be supported by facts, for Dana; in an exhaustive review of the subject, had found that arsenical neuritis might also arise from continuous exposure to small doses, even from poisoning by arsenical wall-paper. Rosenheim is at present disposed to deny that there is a special infectious form of multiple neuritis, and he finds scarcely an autopsy of a case apart from the chemico-toxic forms, where neuritis, has not developed with or after some acute infectious disease or tuberculosis. On the basis of his own investigations he cannot admit that an organized virus is the agent of disease in multiple neuritis. Although autopsies on such cases are rare, nevertheless a certain number of such cases have been reported clinically, as, for example, an interesting series of cases recently reported by Eisenlohr. In regard to the cases of multiple neuritis at the City Hospital, it had seemed to the speaker, judging merely from his own impressions in visiting the hospital since 1883, that the majority of cases had occurred in the last half of each year, being admitted in the late summer and in the fall, and that in the spring and early summer there had been fewer cases. Eisenlohr had found multiple neuritis commoner in certain years, as in 1886–7, and had also seen more cases in the fall and winter. Alcoholic neuritis exhibited two distinct types: the paralytic form with atrophy, and the ataxic form which closely resembled tabes dorsalis. In regard to the paralytic form Buzzard makes the rather remarkable statement that foot-drop is as characteristic of alcohol as wrist-drop is of lead. This is manifestly incorrect, for foot-drop may occur in other forms of neuritis, as the speaker had seen it in lead paralysis and in neuritis after typhoid. There was a symptom-complex, however, from which, without any history of alcoholism, it seemed justifiable to diagnosticate alcohol. That was when, as in Dr. Shattuck's fifth case, there was added to the symptoms of neuritis, a peculiar and characteristic metal condition. The patient became demented, passed urine and fæces in bed, was childish and lachrymose, had various delusions, and while lying helpless in bed would tell a detailed story of going to various remote places, seeing different people, and would give a full account of the conversation held with them. Such a mental condition, when added to neuritis, the speaker believed was almost pathognomonic of the alcoholic form.

Dr. W. N. Bullard desired to draw the attention of the Society to the great similarity between certain forms of multiple neuritis when existing in persons subject to chronic alcoholism, and some forms of general paralysis. In certain cases where the mental weakness was marked, an immediate differential diagnosis was impossible.

Dr. Bullard also asked the reader whether any data had been obtained in regard to the time of the disappearance of the patellar reflex, and the time of its reappearance.

If it can be shown, as seems probable, that in many cases the appearance of this reflex is one of the earliest symptoms preceding many of the more prominent ones, it may be of much value as a means of diagnosticating this disease in the earlier stages.

Dr. T. M. Rotch remarked that during the last year he had had three cases of multiple neuritis under his care, all women. All were extremely hyperæsthetic. In one the mental excitement was extreme, amounting at first to mania and later to imbecility: alcohol appeared to be a cause in this case. In the second case there was no acute mental excitement, but a dull apathetic condition. In the third case there were spasmodic contractions. The cause was not known in the last two cases.

Dr. Myles Standish wished to call attention to a possible relationship between the so-called tobacco amblyopia, or amblyopia *ex abusu* more properly speaking, and alcoholic paralysis. In April, 1886, he reported in the *Boston Medical and Surgical Journal* a case of alcholic peripheric multiple neuritis, which had been preceded three months by amblyopia *ex abusu*; since that time a case that had been under treatment for several weeks at the out-patient department of the Boston City Hospital for amblyopia *ex abusu* was noticed by him to have a peculiar walk, and upon examination it proved to be a case of alcoholic multiple neuritis. He has had still other cases related to him by brother practitioners. The point he wished to make is that amblyopia *ex abusu* may be an early indication of alcoholic peripheral multiple neuritis, and if such is the case the sooner so understood the better.

Dr. Shattuck, in closing the discussion, said with reference to Dr. Webber's criticism upon the number of cases reported as occurring since 1884, that the service to which such cases were apt to be referred was much larger than formerly when Dr. Webber was connected with it, and, moreover, that these cases of multiple neuritis were more generally looked out for and recognized than formerly. There were, undoubtedly, among the fifty-one cases found in the records, several which a strict revision would probably exclude, but there were also others where the diagnosis was not made which ought by such a method to be included. The pathology of the affection is far from being definitely settled.[2] There is an acute degeneration in the course of the peripheral nerve-trunks, but as there is variation in the clinical picture, so there is probably variation in the pathological process. At least, two forms of degeneration of the nerves are accepted. It is not definitely settled whether the cord is involved or not. No constant lesions have been found; an incidental lesion may, of course, be found in the cord or in the brain. The speaker said he knew the cases reported by Dana were not in accord with Brissaud's statement that arsenical poisoning must occur in the severe acute form to produce neuritis; if Brissaud's position were correct it would simplify the ætiology of those cases where the cause

[2] Bernhardt Zeitschrift f. klin. Medicin. Vol. XI, p. 363, 1886. H. Oppenheim, p. 232, 1886.

could not be ascertained, and arsenic in common with other toxic agents might be suspected, as in case No. X of those reported. In this case the urine was examined for arsenic without result, but it might have been too late. To Dr. Bullard's question as to the absence of the patellar reflex, he replied that this symptom was occasionally, but very rarely absent; it was among the early symptoms in its appearance and one of the last to yield, so that some cases were frequently discharged well, or greatly relieved in other respects, whilst the patellar reflex was still absent or much diminished. It was, therefore, difficult to gather useful data in regard to its duration. The speaker was disposed to agree with Dr. Folsom, that contractions and flexions, referred to by Dr. Webber, were characteristic of the more severe forms of the affection, and they had been noted in one or two of the cases reported.

DR. J. B. AYER reported a case of

SEPTICÆMIA FROM PURULENT INFLAMMATION OF THE PORTAL VEIN (SUPPURATIVE PYLEPHLEBITIS).

A lady, seventy-one years of age, has had several bilious attacks (not severe) yearly since the age of eleven, which have not grown worse of late years. He was called to her, October 27th, for bilious vomiting, accompanied by epigastric and general pain, and relieved her by giving a hypodemic injection of morphia. Debility followed the attack, but she had begun to sit up when he again saw her on the morning of November 2d, for severe chills. Eight chills occurred at irregular intervals up to the evening of November 7th. Before the chills the temperature was in the neighborhood of normal, but rose after the chill as high as 105°. During the next four and a half days (up to the 12th) there were no chills, and the temperature became more regular with a higher average. On the 11th it was between 102° and 103°. On the 12th (the last day of her illness) there were three severe chills.

The diagnosis of septicæmia was plain, but its origin was difficult to determine, there being no enlargement of the liver, nor marked enlargement of spleen, no constant epigastic pain, nor *marked* jaundice. Dr. Minot saw her in consultation. The autopsy was made by Dr. Cutler.

DR. E. G. CUTLER, who had made the examination, said there was old inflammatory thickening of the wall of the gall-bladder with adhesions to the front wall of the stomach. In the centre of these adhesions was a perforation, the size of a slate pencil, into the stomach. Several gall-stones were found in the hepatic and common ducts and the mucous membrane was ulcerated in one or two places. In the portal vein near one of these ulcerated ducts was a broken-down thrombus, and scattered throughout the liver were several abcesses varying in size from that of a nickel to a pullet's egg. These abscesses all contained a foul-smelling bloody pus and had ill-defined walls. The hepatic acini were not well marked and the hepatic cells were cloudy.

The spleen was enlarged and very soft (it measured 7 x 4 x 2 ½ inches); on section, the Malpighian bodies were indistinct.

The kidneys weighed each about five ounces and the tubules of the cortex were cloudy and tawney. There was a small cheezy nodule in the upper part of the right kidney.

The heart was moderately filled with a loose dark clot — the muscular walks were friable, and on section proved to be quite fatty. There was slight fatty degeneration of the intima aortæ. The valves were competent, and except two small vegetations on the right anterior aortal segment, were healthy.

The lungs were rather dry, and on close inspection were found to be slightly emphysematous. They were otherwise not abnormal.

The stomach contained a considerable quantity of fluid stained by bile and aside from the perforation spoken of was healthy. The intestines were not abnormal.

The uterus had several very small sub-serous fibroids and a mucous polyp in its interior as large as the last joint of the thumb.

The other organs were not diseased.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT.

STATED meeting, at 19 Boylston Place, October 29, 1887.

Society called to order by the President, DR. JOHN HOMANS, at 8.08 P. M.; seventy-two members present.

The records of the last meeting were read and approved.

The report of the Secretary, giving the names of deceased members, removals out of, into, or within the district, together with the names of newly-elected members of the Society, was given.

The President called for the report of the special committee on the employment of a stenographic reporter.

DR. NICHOLS, for the Committee, said: At the last annual meeting of the Society, the question of employing a reporter, and also of employing a clerical assistant, was referred to the Committee of Supervision, with full powers. They referred it, with full powers, to the Sub-Committee, which presents the following report: The Committee have arranged to have the postal-cards directed for the sum of thirty-five dollars. They have also procured the services of a medical stenographer, at the rate of three dollars an evening, the bills to be presented and paid monthly, and either party to have the privilege of terminating the agreement at any time. The Committee were led to make this arrangement by several facts: First, there was a very general demand on the part of the Society for a stenographic record; second, it was found, upon consultation with the different Secretaries of the Sections, that they were unanimously in favor of such a report of the meetings; and finally, it was found that a gentleman could be obtained possessing medical acquirements, thus answering a serious objection that had been made to the stenographer previously employed. The one objection to the course which the Committee have adopted was the one of expense, and that we felt to be a serious one; but, in guarding against the contingency of a depleted treasury, they have put the whole matter in the hands of the Treasurer, so that he can terminate the agreement at his option.

DR. BUCKINGHAM said: I have the honor of being on that Committee, and there is one thing I wish to say. It is very certain that this Society is going to have extra assessments from time to time. Probably

the extra assessments will be more frequent during the next two or three years than they heretofore have been. This was understood when the Committee took its action, and the Committee understood, too, that there were men in the Society who find it hard to meet their expenses. I speak of this because, when the extra assessment comes, we wish no one to think that the Committee has taken a step in the dark; it has been foreseen.

DR. J. LESLIE FOLEY read a paper on

THE HAIR: ITS DISEASES AND TREATMENT.

DR. O. K. NEWELL demonstrated the use of

LEITER'S PANELECTROSCOPE AND CYSTOSCOPES,[1]

in connection with various kinds of endoscopic tubes, including his own improved patterns of tubes for examination of the bladder. After showing various books and pamphlets, in order to point out the different stages in the development of the endoscope of to-day, he explained the principles on which Leiter's instruments are based, in virtue of which a constant and steady illumination may be maintained.

Members of the Society were then given opportunity to look at the inner surface of an artificial bladder, which had been made for such study.

DR. G. W. ALLEN exhibited a set of

KLOTZ'S ENDOSCOPES,[2]

and reported a series of cases in which they were used.

The President appointed the following Secretaries of Sections: I, M. H. Richardson; II, A. N. Blodgett; III, G. Haven; IV, F. H. Williams; V, G. H. Monks; VI, C. H. Williams; VII, G. F. Jelly; VIII, W. J. Otis.

By vote of the Society, the President appointed the following Committee of five to prepare a list of candidates for officers of the Society: Drs. D. W. Cheever, F. I. Knight, F. W. Draper, E. W. Cushing, A. B. Morong.

Motion for adjournment being in order, the Society adjourned at 9.45 P. M.

Recent Literature.

A Manual of Midwifery. By A. L. GALABIN, M.A., M.D. Small 8vo. pp. 753. 227 illustrations. Philadelphia: P. Blakiston, Son & Co. 1886.

The author has sought to write a book "which should be a manual in point of size, and yet should include all that is likely to be required by students and practitioners": he has succeeded very well. By leaving out the usual description of the female sexual organs and of the development of the embryo, subjects which belong properly to works on anatomy and embryology, space has been saved for the consideration of topics of more strictly obstetrical importance. The book is free from that profuse quotation of authorities, which only embarrasses the student and leaves him in doubt as to what the author himself really believes; and this feature, together with a clear and unassuming style, makes the reading easy and agreeable.

The chapter on Puerperal Fevers is not all that could be desired; but opinions on this subject are in such a state of change, that the perfect portrayal of puerperal pyrexia must not be expected at present.

The chapters on Operative Obstetrics are excellent, although to the American student less valuable, since the descriptions are made with reference to the left lateral position, still the customary one for obstetric operations in Great Britain. For decapitation the author recommends a hooked knife with a serrated edge,— a suggestion worth consideration perhaps, although the combined use of Braun's hook and Ramsbotham, Jr.'s, decapitating knife has proved easy and effectual.

Altogether the book is an excellent one, and well adapted to the use of students.

Hand-Book of Gynecological Operations. By ALBAN H. G. DORAN, F.R.C.S., Surgeon to the Out-Patients, Samaritan Free Hospital for Women and Children, London. Philadelphia: P. Blakiston, Son & Co. 1887.

This hand-book treats of the surgical operations on the female genital organs, leaving out of consideration those minor manipulations and forms of treatment which are usually included in works on gynecology but which are not distinctly surgical. The author's special acquaintance with, and predilection for abdominal surgery as applied to affections of the pelvic viscera, fostered by his connection with the Samaritan Free Hospital, in London, naturally result in a large portion of the work being devoted to this branch of gynecological surgery. In this part of his subject the author is thoroughly at home, and has a great deal to say which is worth reading. This is the most valuable part of the book. The other parts of the work devoted to plastic operations on the vagina and cervix, while fairly well treated, are not especially original nor quite so clearly described as they might be. As a whole, however, it is a very well written and readable book, and one which will well repay study on the part of those general or special surgeons, who are called upon to perform the operations of which the book treats.

To make his work as comprehensive as possible, the author has discussed several subjects which are not usually treated of in similar books, and which lie on the border-line between obstetrics and gynecology. Such for instance are Extra-uterine Pregnancy, Cæsarean Section, and Porro's Operation. Their presence here is, however, quite in keeping with the scope of the book, and distinctly adds to its value.

The illustrations are, as a rule, very good; many of them being original, and drawn from fresh specimens and from preparations in the Royal College of Surgeons. The book is attractively printed and bound.

— It is said that a bill to make vaccination compulsory is soon to be introduced into the Austrian Reichsrath.

— The late Chaplain of Clerkenwell Prison is said to have remarked that at one time that institution contained in separate cells, on charge of drunkenness, a grandmother, a mother, a daughter, the latter with a baby at her breast.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 1, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE VARIATIONS OF THE NORMAL KNEE-JERK.

THE study of the knee-jerk has fairly entered upon the second stage of its existence. In the twelve years that have elapsed since Westphal and Erb first published their discovery of the significance of the knee-jerk, investigators have sought chiefly to explain the mechanism of its origin, and its variations in disease. The second stage in the study, the investigation of its variations in health, may fairly be said to have begun with Jendrássik's [1] discovery that, in health, if a decided muscular effort, such as clenching the hands, was made at the moment the tendon was struck, the muscular response was increased. Jendrássik's discovery was corroborated later by the exhaustive and interesting experiments of Drs. S. Weir Mitchell and Morris J. Lewis,[2] who found that various changes in the activity of the nerve-centres caused corresponding variations in the intensity of the knee-jerk. These experiments have lately been supplemented by a series of extremely valuable and interesting observations made by Dr. W. P. Lombard, and published in the October number of the *American Journal of Psychology* for the present year. Dr. Lombard's observations were made upon himself during a period of six weeks; sixty-six hundred and thirty-nine observations being made at two hundred and thirty-nine different times.

These investigations are more exact than any others that have yet been made, for Dr. Lombard has devised an apparatus which can strike a blow upon the tendon with the same force and upon the same spot each time, while every movement of the foot during the knee-jerk is registered and measured in millimeters. By this apparatus, therefore, a constant force can be given to the blow, and an exact register can be made of the amount of the knee-jerk.

From these investigations, Dr. Lombard has found that the knee-jerk undergoes great variations in health. The average extent of the knee-jerk on rising, when not fully awake, is low; it rises greatly after breakfast, falls off during the forenoon, rises after luncheon, falls off during the afternoon, rises after dinner, and falls again during the evening. There is, moreover, a constant decline during the day, the after-dinner average, for instance, being lower than the after-luncheon average. Fatigue, hunger, sleep, depressing weather, or anything which lowers bodily activity, lowers the average extent of the knee-jerk; rest, a meal, wakefulness, and invigorating weather, which increase bodily activity, increase it. Furthermore, even under circumstances which depress the average, mental excitement may raise it temporarily, while, when in vigorous condition, drowsiness or sleep may depress it. Not only do the various muscular efforts reënforce the knee-jerk, as Drs. Weir Mitchell and Lewis have shown, but various mental stimuli, such as an unusual noise or music, have the same effect. We have not space here to dwell upon all the curious and interesting details of Dr. Lombard's experiments, for which we must refer those interested to the article itself; but these experiments form a most valuable contribution to our knowledge of this important symptom.

THE DOCTOR'S WIFE.

IT is useless to suppose for an instant that any description of the doctor's wife can do justice to her, for doctor's wives differ as stars from each other in magnitude: or, a comparison more to the point, quite as widely as their husbands. It is even doubtful if a composite photograph could so blend their many virtues and individualities as to produce a face in which each community could find their own doctor's wife. But yet, as a class, the wives of physicians possess certain common traits, as well as common graces, which are known and appreciated not only by their husbands, but by all those who possess an extended acquaintance with doctors and their families, though these characteristics are modified by the peculiarities of the woman, and the character of the practice to which she is wedded. The wife of a doctor in general practice differs very decidedly from the wife of a specialist. The business of the latter is commonly confined to certain hours: his office door is tended by a trained servant, who does not need appeal to the wife for information as to the doctor's whereabouts; but, in general practice, when the domestic answers the bell, and holds a parley with the anxious individual who wishes to find the doctor, the doctor's wife is very apt to be somewhere within hearing, at the head of the stairs, or behind the office door, and is very likely to take the conversation into her own hands. She, perhaps, knows the caller, and is able to dispose of him according to his merits. If it is near the time of the doctor's return, she may exercise va-

rious transparent devices for keeping him, allowing him, if he is garrulous, to tell her what has driven him to consult the doctor.

In the early days of her married life, she may have gone forth herself to pursue her husband in his route through the village, to hasten his footsteps in some new direction; but it would take something very unusual to start her off in a chase after the doctor in her maturer years. It seems to be a superstition among the more helpless class of patients that the doctor's wife must have some share of the wisdom which they attribute to her husband, and it is by no means rare for her advice to be asked as to the course to be followed when the doctor himself is not available, and she learns, in the course of years, a series of stock recommendations — that a baby in a fit may be safely put into hot water, that a broken leg can be left an hour or two until the doctor comes.

But there are patients who resent her interference and disregard her suggestions. They will neither tell their errand, nor promise to call again. They arouse, sometimes, her pity, sometimes her curiosity, a quality of which the model doctor's wife should possess but a minimum. She finds it difficult sometimes to manifest a proper interest in her husband's business without appearing too curious. She is seldom a gossip, or, if she is a little talkative with her neighbors, one of the staple topics of conversation will be the dreadful uncommunicativeness of her husband, whom, under such circumstances, she will possibly characterize as "close-mouthed."

The doctor's wife is almost sure to hold strong opinions on hygienic subjects, and she talks with an air of learning about sewers and traps and ventilation. If she is the wife of a doctor who practises in the city, she holds strong ideas about medical charities. Perhaps she appreciates too highly the doctor's unpaid efforts. She has been known to express very radical ideas about hospitals, and night-calls she abominates. She does not like the doctor to imperil his life by attendance on diphtheria. In fact, her constant tendency is to over-value his services. She feels that he does not receive all he ought for the exhausting labor he performs. And yet, with the sweet inconsistency which belongs to the sex, she hurries the good man off on certain occasions. She has been known to drop to sleep after the night-bell had summoned him, and, awakened again by the noise he makes on his return, oblivious of the time that has passed, to chide him that he has not yet started.

She takes it to heart when the doctor is discharged from a case and a rival practitioner installed over it, and if the family who have thought it for their interest to make the change are numbered among her friends, a little coolness is an almost inevitable result. Her life-long friends do not always fully appreciate her husband's peculiar virtues, and it is a constant surprise to her that any of them should continue to employ their old practitioner.

The doctor's wife is usually emphatically the domestic manager. The domestic machinery is of necessity left to her control, for the irregular and absorbing nature of the doctor's vocation renders him somewhat unreliable as a purveyor. He is occasionally absent-minded, even when present in the body. If he undertakes to do the marketing, he will forget to order the dinner. On the other hand, the care of the children is apt to pass into the doctor's hands rather more than in other families. He gets up at night to see why John coughs, and what it is that makes Benjamin so restless.

There is one fond delusion which the doctor's wife hides in her own breast, and never reveals, except to her mother, her sisters, and her few intimate friends, and occasionally to her husband, when he is particularly exasperating: she is sure that her husband's success in his profession is, in reality, due to her. His professional attainments are all very well, but, without her directing hand, who can tell where his lack of worldly wisdom would have led him.

ON THE PATHOGENY OF SEA-SICKNESS.

At a recent meeting of the Society of Biology the subject of sea-sickness was discussed by Dupuy, Dastre Brown-Séquard, Laborde, and others.

Dupuy has found sea-sickness much more frequent and more grave in dyspeptics with dilated stomachs. He has of late been in the habit of recommending his patients to take daily, for two days before and three days after embarkation, thirty grains of antipyrine. In every instance he has had occasion to felicitate himself on the success of this treatment.

Dastre has ascertained, by carefully conducted experiments, that the viscera undergo displacement by the heaving and pitching of the vessel; to attenuate as much as possible this displacement, which is the principal factor in sea-sickness, the organism reacts by contraction of the antagonistic muscles, and especially the diaphragm, and thus a particular rhythm is imparted to the respiration.

Brown-Séquard remarked that it had long been known that sea-sickness results from displacement of the abdominal viscera and consequent traction on the nerve plexuses; on this account he had seen recommended to voyagers abdominal belts with a pad designed to make pressure over the stomach.

Morel thought that there was no doubt that displacement of the viscera, and particularly of the cerebrum, was the chief cause of sea-sickness. What, moreover, proves this, is that every thing which minimizes this displacement, horizontal décubitus, walking, suspension in a frame, etc., attenuates the sea-sickness. It is also worthy of note that the vomiting always follows the pitch of the vessel. Another speaker, who followed Morel, doubted the existence of any cerebral displacement, though conceding that of the abdominal viscera.

Laborde felt inclined to give due weight to the

cases which had been named, but thought that due account had not been taken of nervous predisposition as a prominent factor in the pathogeny of this affection. Sea-sickness, in fact, is a vertigo, and many persons are attacked with it as soon as they get aboard of a ship, even before the least oscillation has been experienced. In such persons every kind of treatment is certain to be futile.

AUSTIN FARM AND THE SUFFOLK COUNTY INSANE.

FOR a good many years the city of Boston has been considering the question of what should be done for its insane. The accommodations in the city asylum are substantially what they were forty years ago, so that to-day the city is forced to keep some seven hundred of its insane, away from the reach of their friends and their families, in the State institutions. These are already overcrowded, and the day cannot be far distant when the law requiring Boston to care for its own insane in a city asylum must be enforced.

When the plan arose for transferring the various pauper institutions to Long Island, the suggestion was made that some relief for the present state of affairs in regard to the city's insane might be obtained by converting the buildings at Austin Farm — then the asylum for female paupers — into an asylum for the insane. This plan met with the approval of Dr. Fisher, the Superintendent of the Boston Lunatic Hospital, who, in his last three reports, has urged its acceptance, and has suggested the details requisite for putting it into successful operation. Having made a careful inspection of the buildings, he decides that they are not suited for violent or sick patients unless extensive repairs should be made. With slight changes, however, they would be well adapted for quiet, mild cases. He furthermore objects to limiting the institution to chronic cases, for he believes that it would often be advantageous to send mild acute cases and convalescents there, and that it would be well to send other selected cases there for a few weeks for the benefit of change of scene. His plan contemplates that Austin Farm should be regarded as a branch of the Boston Lunatic Hospital, with a resident assistant physician, but under the same management as the Lunatic Hospital, so that transfers of patients from one institution to the other might be made without any legal formalities, just as patients are now transferred from one ward to another.

This plan involves no extraordinary expense; it is simple yet well-adapted to the situation, and it affords an excellent opportunity for a suitable classification for the insane. It has not, however, met with the approval of the Board of Directors of Public Institutions. They have seen fit to establish at Austin Farm a separate and independent institution for the care of the insane, and have put it in charge of a gentleman, who, although skilful and experienced as a general practitioner, is entirely lacking in the special training and experience requisite to fit him for that position.

In former days the Board of Directors of Public Institutions was made up of gentlemen whose character and high-standing in the community were sufficient assurance that the institutions should be conducted with the highest regard for the welfare of their inmates and for the public good. The Board, as at present constituted, has greatly deteriorated. Various acts of late indicate that its members are "there for the offices," and that they are disposed to use those within their gift for the benefit of their friends. Their course in regard to Austin Farm is indefensible. Without any satisfactory reason they have rejected the carefully-studied plan of an expert in asylum management for a scheme similar to that employed in our State asylums, which has incurred the criticism of all competent alienists, who regard proper classification of the insane in asylums as a crying need. Worse than this, however, they have gone back to the old method of treating the insane as paupers, to be shut up in a county almshouse under the care of some local practitioner. That is a method which enlightened communities have abandoned. Furthermore, their appointment of a superintendent must be condemned. No man is fit for such a position unless he has had the special education and training which render him qualified to speak and act as an expert in mental diseases; lacking such training he is unfit for the position, and his appointment is wrong. The last place where personal favoritism or political influence should prevail is in an insane asylum. The Cook County asylum in Illinois shows the results of political influence in its management, and, if the reports from it be true, its example is not one which Suffolk County would do well to imitate.

MEDICAL NOTES.

— Dr. J. W. White, physical director of the University of Pennsylvania, has offered, in the name of the University, a prize of excellence in general athletics to the principal schools in Philadelphia.

— In the report of the Customs Inspector at Shanghai, China, a case is reported in which a young man had lost an eye by puncture for his father's debt; the physician called in attendance was successful in saving the other eye, but the injured eye was lost. The practice is said to be common in some districts of China, and the attention of the Government has been called to it.—*Medical News.*

— Apropos of the cases of mischief following the puerperal use of corrosive sublimate recently referred to in the JOURNAL, we note that in a paper on the "Washing out of the Puerperal Uterus," Dr. Halliday Croom has collected reports of four fatal cases after mercurial irrigation, and thirteen cases followed by serious symptoms. The strength of the solution, when

used, should not be stronger than 1 in 5,000. In cases of anæmia and renal disease, he says, corrosive sublimate should be avoided altogether.

— A report on the case of the Crown Prince of Germany, covering the time from his visit to England up to November 10th, has been published by Sir Morell Mackenzie simultaneously in the medical journals of England and the *Berliner Klinische Wochenschrift*, by the request of the Crown Prince. After giving the history, of the substance of which our readers have already been informed, he concludes: "In my opinion the œdema is due to limited perichondritis, which, in its turn, has probably been set up by the growths which have been formed from time to time in the larynx. Although the nature of the growth which has lately appeared has not been determined by microscopic examination, it presents every appearance of cancer."

— Mr. Justice Kay, in the case of C. A. Vogeler & Co. *v.* Middleton, recently before one of the English Courts, was asked to restrain the defendants from advertising and selling an oil as St. Joseph's Oil, as being an infringement of the plaintiff's trade-mark, and calculated to deceive the public. The judge after remarking that both the plaintiffs and defendants were vendors of quack medicines which were largely advertised to heal all manner of external injuries, declined to rule that the use of any saint's name in the calendar was an infringement of the plaintiff's trade-mark. But lest either party should use his judgment as an advertisement, he hoped they would add that no one should employ either preparation except under medical advice. We fear that neither party will be likely to conform to the judge's excellent counsel.

— A correspondent of *Science* calls attention to the fact that the discovery, through the experiments of Goldscheider, and of Dr. Donaldson and Prof. G. Stanley Hall in Johns Hopkins University, to prove the existence of a separate system of nerves for temperature, was anticipated by Sir William Hamilton. His observations of psychological phenomena seem to have been nearly as extensive as his philosophic reading. In his edition of Thomas Reid's works (vol. ii. p. 875), after commenting on a singular and exceptional case of paralysis, in which sensations of touch did not seem to be localized, he takes the occasion to hazard the conjecture, based upon observations of his own, that there is a distinct set of nerves for sensation of temperature. His language is:

"I may notice also another problem, the solution of which ought to engage the attention of those who have the means of observation in their power. Is the sensation of heat dependent upon a peculiar set of nerves? This to me seems probable, (1) because certain sentient parts of the body are insensible to this feeling, and (2) because I have met with cases recorded, in which, while sensibility in general was abolished, the sensibility to heat remained apparently undiminished."

BOSTON.

— The Boston Medical Library has received a legacy of $2,000 from a source as yet not publicly announced, and also the sum of $500 from an equally modest benefactor, the latter sum being given as a specific contribution towards the new building for which the society has just acquired land.

NEW YORK.

HOSPITAL SATURDAY AND SUNDAY FUNDS.

— At a meeting of the Hospital Saturday and Sunday Association, held November 20th, the annual statement from the twenty-eight hospitals included in it was presented. This forms the basis for the distribution of the annual hospital collection, and it appears that during the past year the total expenditures of those institutions amounted to $740,722.27. Their total income from invested funds was $142,147.85, leaving $598,575.42 to be raised for their support. Towards this the hospitals received $56,355.51 from the city, and $163,808.09 from paying patients, and the balance of about $300,000 was left dependent upon private contributions, including the annual hospital collection. In the department of work the following showing was made: The number of house or bed patients was 13,920, of whom 10,157, or about 75 per cent., were free patients. In addition, there were treated 119,124 free dispensary patients, who made a total of 365,920 visits. A committee on dispensaries reported in favor of a scheme by which dispensaries connected with hospitals should be entitled to share in the distribution of the general collection fund.

Miscellany.

HYSTERIA AND HYSTERO-EPILEPSY IN SOLDIERS.

The *British Medical Journal* quotes from the *Weekblad van het Nederlandisch Tijdschrift voor Geneeskunde* an account by Dr. Janssen of several cases of hysteria and hystero-epilepsy occurring amongst Dutch soldiers. In one of the latter class of cases occurring in a man of twenty-one, who had come of a highly neurotic family, where there were several attacks during the day characterized by semi-consciousness, extremely rapid respiration, abdominal tenderness, coldness of the extremities, with cold sweating, pulsation of the carotids and other arteries, opisthotonos, and convulsive spasms of the extremities, Dr. Janssen found that the attacks could be arrested by exerting firm and deep pressure with the closed hand on the left iliac region, or by a powerful induced current. The surface of the body was anæsthetic, and if the skin were lightly pricked with a pin, not only did the man not cry out, but no blood appeared. Various anti-epileptic and anti-hysterical remedies were tried without benefit. Different metals were applied to the surface of the forearm, but the only one which produced any effect was silver, which left a red mark. This induced Dr. Janssen to prescribe nitrate of silver for internal use, and this produced a

great improvement in the patient. In another case there was aphonia and aphasia, the lad being able to understand what was said to him, and to read and write, but not to speak — an example of Charcot's hysterical mutism. Treatment produced no effect upon this patient, and he had to be discharged from the army.

DISINFECTION AT THE NEW YORK QUARANTINE.

DR. G. M. STERNBERG, in his presidential address at the late meeting of the American Public Health Association, gave the following account of the ceremony performed at the New York Quarantine, as observed by him when entering that port last August on a vessel from Brazil:

"As another illustration of the evils arising from the present system of supporting quarantine establishments, I will mention a circumstance which occurred upon our arrival at the port of New York. With the deputy health officer, who boarded our ship, came a man with a jug. I was informed by one of the officers of the ship that he was to disinfect the vessel. Being somewhat curious to know the method of disinfection employed, I asked the ship's surgeon to go with me to inspect, when, after a detention of less than one hour, we had started from the quarantine station for our wharf. We found that the man with the jug had lowered a bucket by means of a rope through one of the hatches between decks. Upon pulling up this bucket, I found that it contained two or three pounds of some powder, which had been wet, probably with acid solution, and which gave off an odor of chlorine. No doubt, when first lowered between decks, there had been a considerable evolution of chlorine, but, in the vast space to be disinfected, it was so diluted that at the end of an hour I did not detect the odor of chlorine gas when I lifted the hatch, and it was only by approaching my nose to the bucket that I was able to ascertain what disinfectant had been used. The most curious part of the story is that I was informed that the bucket had been lowered between decks to disinfect a quantity of hides which were stored in the hold. What was the object of this 'disinfection'? Evidently not to disinfect, for no one at the present day would think of maintaining that the hides in the hold had been disinfected by the procedure of the man with the jug.

"The only object that I can conceive of depends upon the fact that there is a fee for disinfecting, which must be paid by the agents of the ship; at least, I was so informed by the officers of the ship."

CASES OF ADDISON'S DISEASE.

AT a recent meeting of the Liverpool Medical Association, as reported in the *Medical Press*, Dr. Davidson showed one patient suffering from this disease, and referred to two other cases recently under his care. The patient exhibited was a sailor, aged twenty-seven, and the disease had existed about three years. A few months ago, when he attempted to resume work, his symptoms became more aggravated, and he was admitted into the Liverpool Royal Infirmary. The patient was deeply bronzed, especially on the face, back of the hands, and other parts exposed to the air; also on the left side, where blisters had been applied eight years ago for an attack of pleurisy. There were also deeply pigmented patches on the lips and mucous membrane of the cheeks. When he was admitted into the Infirmary, three weeks ago, his debility was so great he could hardly stand or walk; he had much abdominal pain, and intense vomiting. He was kept in bed, blisters were applied to the epigastrium, and, when the sickness subsided, twenty grains of iodide of sodium were given daily. The urgent symptoms had now abated, but the bronzing of the face had perceptibly increased since his admission. Dr. Davidson referred to two other cases of Addison's disease recently under his care. In one of the other cases described, the patient, a man aged thirty-three, died from exhaustion three months after the first appearance of the symptoms. He had great muscular weakness, vomiting, and abdominal pain and bronzing. At the post-mortem examination, the supra-renal capsules were seen to be masses of curdy, tubercular matter, and were matted to the surrounding tissues. The left testicle was tubercular, and there was an encysted empyema in the right pleura. The other case was an interesting example of disease of the supra-renals without bronzing of the skin. The patient, a man aged forty-five, was admitted into the Royal Infirmary in July, 1883, in a state of extreme exhaustion and emaciation, like the collapse of cholera. He had caught cold two months before, and since that time had gradually got weaker, and suffered from inability to take food. He had no vomiting and no diarrhœa till just before his admission. He died next day. On post-mortem examination, both supra-renal capsules were found to be much diseased, and adherent to the neighboring tissues. The left was completely destroyed, its structure being replaced by caseous and calcareous matter. The right was enlarged, hard, and fibrous, with small calcareous deposits. No apparent change in the sympathetic nerves.

THE DIETETICS OF MUSTARD AND PEPPER.

DR. P. BURJINSKY, one of the house-physicians (ordinator) to Professor Manassein's clinic, has described, in his St. Petersburg Inaugural Dissertation for 1887, (see *London Medical Record*, November 15, 1887), the results of an experimental inquiry into the influence of two of the commonest condiments — mustard and pepper — on assimilation and metabolism. The author's experiments were conducted on nine quite healthy persons (including himself and a lady), aged from twenty-two to thirty. In one series of the experiments, five in number, the influence of mustard (the best Sarepta sort) on the assimilation and metabolism of nitrogenous constituents of a mixed food was studied. In another group of four, experiments, the same points were elucidated in regard to pepper, the best—so-called "Russian" — sort of the *piper nigrum*. Finally, in a third category, including two experiments, the influence of mustard on the assimilation of fats of cow's milk was inquired into. Each observation in all the three groups was divided into two periods, each of several — from three to seven days' duration — during the first of which the subject experimented upon was receiving no condiment; while during the subsequent one, he or she in-

gested daily either mustard or pepper, all other conditions remaining as equal as possible from the beginning to the end. The results of Dr. Burjinsky's laborious and scrupulously careful experiments may be summed up as follows: 1. When given with meals in small quantities, in the daily amount varying from 8 to 18 grammes of the condiment prepared of 50 grammes of the mustard-flour and 80 grammes of warm water — that is, when taken exactly as in daily life — mustard does not show any influence on the assimilation of nitrogen of mixed diet (consisting of butcher's meat, milk, white and rye bread, potatoes and beef-tea, and tea). 2. Pepper, in the daily quantity from 0.7 to 1.0 gramme, lowers the assimilation, the decrease varying from 0.4 to 2.3 per cent. 3. Mustard, in the daily amount of 4 to 10 grammes, lowers the assimilation of fats, the fall amounting to 2.2 per cent. 4. Neither mustard nor pepper show any influence on the systemic metabolism. 6. Mustard somewhat improves appetite, while pepper diminishes it. 6. Mustard has no influence on the daily quantity of urine, though Dr. Lauder Brunton, in his classical *Text-book of Pharmacology*, 1885, p. 379, regards the condiment as a diuretic. 7. But pepper, as a rule, increased the secretion of urine, the daily surplus varying from 3 to 14.8 per cent. The urine at the same time acquires a strongly pronounced characteristic odor. Probably both the diuresis and odor should be attributed to the presence of an essential oil isomeric with turpentine (Flückiger). 8. Both mustard and pepper very frequently give rise to gastro-intestinal disturbances — colics, diarrhœa with eight to ten stools a day—in persons unaccustomed to the use of the condiments in question.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 19, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				Infectious Diseases.	Consumption.	Typhoid Fever.	Diph. & Croup.	Scarlet Fever.

Deaths reported 2,274: under five years of age 733; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 385, acute lung diseases 363, consumption 311, diphtheria and croup, 195, scarlet fever 46, typhoid fever 46, diarrhœal diseases 40, malarial fever 19, measles 11, cerebro-spinal meningitis nine, whooping-cough seven, erysipelas seven, puerperal fever four. From diarrhœal diseases, New York 18, New Orleans eight, Baltimore and Lowell three each, Boston and Brooklyn two each, Pittsburgh, Springfield, Gloucester and Waltham one each. From measles New York six, Baltimore three, Boston and Chelsea one each. From cerebro-spinal meningitis, New York four, Somerville three, Worcester and Lynn one each. From erysipelas, New York three, Philadelphia and New Orleans two each. From whooping-cough, New York two, Brooklyn, Baltimore, Boston, New Orleans and Nashville one each. From puerperal fever, Philadelphia, District of Columbia, Springfield and Chelsea one each.

In 22 cities and towns of Massachusetts with an estimated population of 1,082,707, the total death-rate for the week was 21.90 against 20.85 and 20.42 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending November 5th, deaths reported 3,800: infants under one year of age 902; acute diseases of the respiratory organs (London) 506, scarlet fever 144, diarrhœa 77, measles 75, whooping-cough 60, fever 57, diphtheria 57, small-pox (Sheffield) 21.

The death-rates ranged from 12.7 in Hull to Halifax 31.0; Birmingham 17.5; Bradford 22 5; Derby 25.0: Liverpool 21.7; London 21.5; Manchester 23.1; Newcastle-on-Tyne 26.6; Nottingham 18.2; Sheffield 25.6.

In Edinburgh 16.1; Glasgow 22.4; Dublin 31.0.

The meteorological record for the week ending November 19, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Nov. 19, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 19, 1887, TO NOVEMBER 25, 1887.

PERIN, GLOVER, colonel and assistant surgeon general. Retired from active service November 17, 1887, by operation of law. S. O. 268, A. G. O., November 17, 1887.

SMITH, A. K., lieutenant colonel and surgeon. Assigned to duty as attending surgeon in New York city.

SMITH, J. R., lieutenant colonel and surgeon. Ordered for duty as Medical Director, Department of Dakota.

HORTON, S. M., major and surgeon. Granted six months leave of absence on surgeon's certificate of disability.

ARTHUR, W. H., captain and assistant surgeon. Granted two months leave of absence, with permission to apply for two months extension, to take effect on the arrival at Fort Niagara, N. Y., of assistant surgeon Paul R. Brown.

KEAN, J. R., first lieutenant and assistant surgeon. Granted two months leave of absence, to take effect about December 1. S. O. 269, A. G. O., November 18, 1887.

BROWN, PAUL R., captain and assistant surgeon. Ordered to Fort Niagara, New York.

SKINNER, JOHN O., captain and assistant surgeon. Ordered to Fort Ontario, New York.

RICHARD, CHARLES, captain and assistant surgeon. Ordered to post near Denver, Colorado.

CARTER, E. C., captain and assistant surgeon. Ordered to Willett's Point, New York. S. O. 270, A. G. O., November 19, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 26, 1887.

NASH, F. O., passed assistant surgeon. Detached from duty at the Smithsonian Institute, and ordered to the Washington Navy Yard.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.— There will be a meeting of this Section at 19 Boylston Place, on Wednesday evening, December 7th, at 8 o'clock. Dr. Edward Reynolds will report a case of "Stricture of the Rectum Treated by Incision." Drs. E. H. Bradford and M. H. Richardson will read papers on "The Treatment of Inflammations in the Neighborhood of the Cæcum," and will report cases.

G. H. MONKS, M.D., *Secretary*.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — The regular meeting will be held at the Medical Library, 19 Boylston Place, on Monday evening, December 5, 1887, at 8 o'clock. Readers: Dr. H. E. Marion, "Pyo-pneumothorax with Autopsy, in a Subject with Extreme Retro-lateral Curvature of the Spine." Dr. A. N. Blodgett, "Twelve Years in the History of the Development of a Case of Moral Imbecility of the Pomeroy Type." At *nine* o'clock balloting for new members.

CHARLES P. STRONG, M.D., *Secretary*.

OBITUARY. FREDERICK HYDE, M.D.

Dr. Frederick Hyde, who died in Cortland, N. Y., October 15, 1887, practised his profession successfully in that neighborhood for more than fifty years. Up to within a few days of his death he performed difficult surgical operations with his accustomed skill and zeal. He was Professor of Surgery in the Syracuse Medical School, in which department he had been busy as a teacher for forty years. Notwithstanding his arduous and continuous duties as a practitioner, Dr. Hyde found time to give to many things which concerned the general public welfare. He was at the time of his death, President of the Cortland Normal School; president of the Cortland Savings Bank; trustee of the Franklin Hatch Library Association, and of the New York State Idiot Asylum. Dr. Hyde will be greatly missed in the community in which he lived and worked.

DEATHS.

Died in Westfield, Mass., November 23, 1887, James Henry Waterman, M.D., M.M.S.S.

In North Abington, Mass., November 25, 1887, Nelson Briggs Tanner, M.D., M.M.S.S., aged seventy years.

THE TREATMENT OF PULMONARY PHTHISIS BY THE PNEUMATIC CABINET, WITH A REPORT OF CASES.

BY D. ROLLINS BROWN, M.D, BROOKLYN, N. Y.

The therapeutic history of Pulmonary Phthisis is disheartening. The numerous remedies that have been brought to our notice from time to time, as having an especial preventive or curative influence upon the disease, have so far failed to fulfil the promises made for them, that its continued and dreadful mortality is regarded as a reproach to medical science, and presents a pathetic contrast to the inherent optimism of its subjects. Mindful of a past so full of discouragement, medical men very naturally doubt the efficiency of whatever remedial measures may be proposed. This attitude is praiseworthy, if it implies a willingness to investigate theory, to sift, and honestly adjudicate upon, the evidence furnished by practice. Herein lies the true conservatism: it never degenerates into carelessness or indifference — counterfeit presentments against which the most candid minds must ever be on guard. One of the latest candidates for favor in the management of pulmonary disease, is the instrument known as the Pneumatic Cabinet. Dr. Williams of Brooklyn, to whom we are indebted for the suggestions out of which it grew, has spent much time and labor to perfect its mechanism, and to present its theory and practice to the profession. Whatever its achievement, to him and his co-workers, is due the credit of having furnished means for making exhaustive study of aero-therapeutics. Moreover, the advent of this method has quickened scientific thought, and aroused fresh endeavor to the end that the resources of medicine shall be made more equal to the consumptive's need. The time is marked by the appearance of fresh devices for the relief of these cases, and there is much to encourage a belief that phthisis is at length taken from the list of ailments whose management must be left to the inadequate operation of general principles. Knowledge that an intimate relation exists between the bacillus of tuberculosis, and the disease seated in the lungs, indicates the line along which search for the remedy is likely to be rewarded, and it is with direct regard to this knowledge, that the cabinet has been constructed. While furnishing the mechanical, it proposes to convey to the site of the morbid process, its chemical antidote. That it does the former cannot be denied; as to its ability to do the latter, there is diversity of opinion among physicians, arising, it must be supposed, from a misunderstanding of the physical laws involved in its operation. Perfect comprehension of them must be followed by the conviction that topical application can be made to the lungs, though perfect clinical demonstration of the fact, and of its value, must await the discovery of an antiseptic, and a germicide, that shall fulfil necessary conditions. Doubtless the instinctive hostility of the profession to trade-marks, has been prejudicial to the instrument, but objections based on the ground that it is patented have no special application, while the policy that has governed its introduction and distribution has been such as fully to conserve the interests of both physician and patient.

Already, Pneumatic Differentiation has a considerable literature. Articles upon the subject have been read before representative medical societies, and have been widely circulated through the columns of the medical press. Discussion has been free, and criticism on the whole favorable, though participants, in their desire to avoid the charge of enthusiasm, have been in danger of according the faint praise that damns. Still, medical journals, and medical societies, are not practitioners, and, until the interest of the individual is enlisted, the true place of this system among remedial agents cannot be established. The profession, having authoritatively consented to give its claims serious consideration, should hasten to define its sphere, its range, and its degree of usefulness as soon as may be. A review of papers containing reports of cases treated by this method, shows a most gratifying uniformity in the results obtained by different observers, making due allowance for the personal equation. Essentially the same experience has been common to them all. Whatever the potent factor in the operation of the cabinet may be, it is a constant one, and will invariably accomplish the same work; it is for the physician to determine the pathological conditions to which its application is best adapted.

Practice thus far has verified the original prediction that the greatest advantages would be derived from its employment in the very first stages of disease. In my own experience, the largest measure of success has been met with in cases where the morbid process had just begun. We are not to withold our confidence because the number of recorded cures is not greater, especially in view of the declaration made by several investigators, that they purposed to deny credit whenever questionable, and to reserve the word "recovery," until sufficient time had elapsed after suspension of the treatment, to fully warrant its use. A majority of the cases treated have been improved. Some to a remarkable degree. A few have been cured. Opium derives its value largely from its ability to control distressing symptoms, and tracheotomy maintains its place because occasionally successful. This treatment, so far from being incompatible with the plan generally pursued, is distinctly adjuvant, and the rapid and decided gain in weight which has followed its systematic employment may be partially attributed to the attendant increase in functional activity through its influence upon the circulation.[1] An immediate gain in digestive and assimilative power has been noticed in every case of beginning phthisis that has come under my care. There is little difficulty in crowding nourishment upon these patients. They are directed to take food, usually milk, or bovinine, every two hours between meals until bed-time, and, if they wake in the night, to drink the glass of milk placed by the bed-side when they retire — and I rarely write for pepsin. This over-feeding has been found practicable in some third-stage cases, and, that too, when digestion has been habitually poor, according to the history.

In favorable cases I am accustomed to look for improvement within a dozen treatments covering a period of three weeks, and relief of symptoms sometimes follows the first inhalation. Considering the pronounced effects, local and systemic, of which the cabinet is capable, contra-indications are few, and so far as demonstrated, do not regard the pathology that belongs to phthisis. With the exercise of ordinary care in diag-

[1] The Physiological Action of the Differential Process on the Circulation, by E. Tiegel, M.D. Journal of the American Medical Association, November 28, 1885.

nosis, its application can do no harm. This negative quality is not to be despised; measures which fail to do good, often do ill. They know it, whose stomachs are unfitted for the performance of their simplest offices by the orthodox exhibition of cod-liver oil; they know it too, whose fruitless pursuit of health from west to south, has left them, with scarcely vitality enough to permit them to meet the inevitable amid the comforts of home. Not that I disparage climatic change, it is often of the greatest value, but it should not be counselled unless very clearly indicated; if not advantageous, it is pernicious. The cases most likely to profit by a change of climate are those most likely to respond to treatment in the cabinet. It has seemed to me also, that a brief experience of this treatment, immediately preceding migration, is calculated to put patients in the best possible condition to appropriate the benefit sought. For a majority of consumptives, change of climate is out of the question, to them particularly, the cabinet holds out a substantial hope. In view of the reasonableness of the method, its accessibility, its accomplishment, we are warranted in giving it tentative recognition; a trial involves no risk in itself, and will not conflict with the use of other generally approved agents.

It is desirable that the instrument be kept in legitimate hands. Having received scientific endorsement, it must have professional support, otherwise we shall suffer the humiliation of having enlarged an unusual opportunity for the quack to enrich himself at the expense of everybody but the manufacturer. I will only suggest the probable usefulness of the method in preventive medicine, in view of the fact that phthisis usually begins in the unexpanding apices of the lungs. If these regions are aerated and rendered aseptic, important conditions favorable to the lodgment of tubercle will have been removed.

In February, 1886, my associate, Dr. Sidney Fox, and myself, in a paper read before the Kings County Medical Society, reported "Sixty-nine cases of lung disease treated with the Pneumatic Cabinet." [2] Of these thirty-four were cases of phthisis. Among those reported by us as "improved" was the case of Mr. C., to the clinical notes [3] of which I desire to revert briefly. This man had a cavity in the right lung in a state of activity. His weight had dropped from one hundred and forty to one hundred and fifteen pounds during his illness. He was very weak, with troublesome cough, profuse expectoration, and night-sweats. Pulse, 120; temperature, 102° in the morning. He was discharged April 1, 1886, having had seventy-two treatments. His weight was then one hundred and thirty-two pounds. There were no subjective symptoms, and physical exploration detected no evidence of active disease in the lungs. With a view of ascertaining the permanency of this result I requested a statement of his condition from his friends in March of the current year. At that time his mother wrote that he was in good health. His weight was one hundred and forty-four pounds.

The present condition of another case of phthisis among those reported "improved" is equally gratifying. Here, also, the disease had gone on to the third stage. This patient, a lady resident in Brooklyn, suspended treatment nearly two years ago. Since then she has remained well, given birth to a healthy child, performed all the offices of maternity, and assumed matronly proportions. Of the subsequent history of the other cases in this class I have no accurate knowledge. The case of fibroid phthisis reported, afterwards developed tuberculosis, and, by the advice of the attending physician, moved out of the city.

The following table includes all the cases of phthisis that have come under our care for special treatment from February, 1886, to August, 1887: —

Whole number of cases	38
Treatment followed by no improvement	11
Treatment followed by slight or temporary improvement	7
Treatment followed by improvement	13
Treatment followed by remarkable improvement	7
Deaths	6

It is, of course, impossible to express in a general statement, the impression gained by almost daily observation of cases under treatment, but the limits of a paper preclude the full reproduction of clinical notes, and I can only define broadly the meaning which the terms used are intended to convey: By "slight or temporary" improvement is meant the amelioration of more prominent symptoms, as cough, sense of thoracic oppression, night-sweats; under "improvement" are included cases in which the treatment has been followed also by a gain in weight, partial restoration of appetite and strength, in women frequently the return of the menstrual discharge; on auscultation, a diminution in the number, and occasionally the disappearance of râles for varying periods; "remarkable improvement" describes cases in which, in addition, there has been a decided gain in weight, and, in some instances, entire cessation of symptoms, with objective evidence of quiescence of the disease for considerable periods. Of the seven cases under the head of "remarkable improvement," two were diagnosticated as fibroid phthisis, three as phthisis in the first stage (beginning consolidation), two as phthisis in the third stage (*a*, softening, *b*, cavernous.) In one of these last cases there was complete abatement of symptoms, and a gain of thirteen pounds in weight, after thirty-three treatments, occupying three months. The other will be found reported in detail. In a succeeding paper I hope to present the further history of these seven cases. That some knowledge may be had of the data upon which judgment of the results of treatment has been based, the clinical history of two cases is appended.

Miss ———, age thirty. Family history, negative. Personal history: in good health up to the fall of 1883; dates illness from a cold contracted at that time; cough at first dry—no expectoration. In the spring of 1884 had four distinct hæmorrhages, each following a violent paroxysm of coughing; cough afterwards became looser; soon began to notice failure in appetite and strength. These symptoms increased during the summer. In the winter of 1884-1885 she went to Colorado; remained there nine months without much benefit. Soon after her return the cough became severe, and attended with considerable expectoration; she suffered from wandering pains in the chest, hoarseness, night-sweats, and increasing debility. The case came under my care in May, 1886. She was then extremely anæmic; had lost seventeen pounds in weight; had little appetite; feeble digestion; complained of thoracic oppression—"felt as though she were breathing through a pin-

[3] Page 17 of pamphlet cited.

hole"; was short of breath; unable to lie on the right side; cough troublesome; sputa greenish in color; night-sweats; constipation; menses regular. Physical examination: chest flattened on the right side; marked dulness on the right side from apex to third intercostal space, and from the sternum to within two inches of the axillary line; dulness in corresponding region behind; high-pitched note over left upper thorax. Tubular breathing over right upper chest, with increased voice transmission; moist râles throughout the chest on both sides, distinctly audible for a distance of several feet; masked crackling over right upper chest; at left apex expiratory sound is harsh and prolonged. Chest expansion one inch and a half. Temperature 100.75° (10 A.M.); pulse 108; weight 95½ pounds. Sputa contain *bacilli* in considerable number. [3 on a scale in which 5 represents the maximum.]

Treatment was begun on May 30, 1886, and administered daily until June 5th. The relief to symptoms was considerable: Cough decreased; "pin-hole" respiration disappeared; night-sweats ceased. During a visit to New Jersey the patient had a sharp hæmorrhage, and spat up a large quantity of "matter." Returned, June 11th, feeling very weak. Treatment was resumed and continued daily up to July 1st, when she started for the White Mountains. She expressed herself as feeling much better; rested well at night; was able to lie on either side; coughed and raised much less; had no night-sweats; ate pretty well, and was stronger. Internal treatment was confined to the exhibition of a bitter tonic, and the occasional use of pepsin. Trial was made of the hypophosphites of lime and soda, and of different preparations of iron, but they were not well borne. The diet was made as full as possible, milk and bovinine being taken between meals. Physical examination, June 30th: moist râles have entirely disappeared in the left lung, and are very much lessened in the right; no appreciable change in other signs, but there is now evidence of a cavity on the right side. Expansion two inches. With one exception the recorded morning temperature dip not go above 99.5° during June. Patient returned from the mountains in September. During her absence took tonic doses of arsenious acid three times a day. Came back with former symptoms renewed. Cough keeps her awake at night; chest very sore; appetite poor. In August passed a menstural period for the first time. Temperature 100.4°; pulse 135; weight 93 pounds. Resumption of treatment was promptly followed by improvement, though during September frequent use of the zinc and belladonna pill was made to control exhausting night-sweats. Weight, September 30th, 91¾ pounds. October 6th the case was seen by Dr. A. L. Loomis, of New York, who reported that he found a cavity in the right lung, and first stage phthisis in the left. He advised rest, a full diet, and persistence in the cabinet treatment. During the remainder of October treatments were given every other day. The recorded morning temperature did not go above 99° during the month, and was often below the normal point. She made no gain in weight, but experienced much relief of symptoms. During November the advance was marked; cough almost entirely disappeared; there was little expectoration, the sputa being white instead of a greenish yellow; rested well at night; menses returned (after an absence of three months); prevailing morning temperature, 98.5°; weight, November 30th, 96¼ pounds; *bacilli* absent. She began to take gradually increasing doses of pure cod-liver oil in October, and by the end of November was having half an ounce of it, an hour after each meal, and some form of nourishment every two hours, without digestive disturbance. This improved condition has lasted, with few interruptions, up to the present time (September). Regular treatment was suspended in March. In February no signs of progressive disease were discovered on physical examination. Signs denoting a cavity excluded, the abnormal respiratory sounds were limited to harsh breathing over both upper thoraces, with a crackle on the right side. Good reports have been received from the patient and friends during the summer. She now weighs one hundred pounds, coughs very little, and raises only in the morning. This case is classed under "remarkable improvement."

Mr. S., age 19 years. Dispensary case. A brother and a sister died of consumption; the father has lung disease: mother in good health; beyond this nothing known of family history. Personal history: first noticed a hard cough in September, 1886, which has persisted up to the present time (November 24, 1886), no expectoration. Early in November had a hæmorrhage, following violent exercise; then coughed up "three or four cupfuls of blood and froth"; has had frequent hæmorrhages since, all crimson in color; for some years has had stitch-pains in the left side. In October, first noticed failure in appetite, and loss of flesh and strength. In September, October and November, had repeated attacks of diarrhœa, lately has had profuse night-sweats two or three times a week. Physical examination: a tall youth, sallow, and narrow-chested. On percussion a high-pitched note is heard over the top of both lungs. In these situations the breathing is harsh, with a friction sound at the summit of the left chest. Weight, 129 pounds; pulse 130; temperature 101.75° (9 A.M.) The case was seen for the first time November 24, 1886. ***No treatment was given.*** The next day alarming hæmorrhages set in, which were not fully controlled, with the usual remedies, until December 5th. He came to the office for treatment December 9th, was then extremely pale, and seemed very weak. Temperature 97°, weight 122½ pounds. Improvement dated from the first inhalation, and was remarkable in rapidity, and degree. On the 27th of February, 1887, with daily sittings, his weight was 134½ pounds; he had had no night-sweats for two months; appetite was excellent; cough had entirely disappeared. His mother sent word that he seemed perfectly well, and suggested that he might be allowed to go to work again. Good resonance was found on both sides on percussion, and though the breathing was still somewhat harsh, no friction sound could be detected anywhere. Expansion four inches. Temperature 99°. Early in March he obtained light employment and continued the treatment bi-weekly. On the morning of March 16th, he coughed up some dark-colored blood mixed with mucus. On the 19th, had a slight hæmorrhage, and complained of chilly sensations. Hæmorrhages occurred also on the 20th and 21st, and on the 22d he had a night-sweat. The cough had returned. Daily treatments were advised. Weight was now 126½ pounds. Unfavorable symptoms continued until the 8th of April, when he again began to gain. On the 27th his

weight was 131 pounds; the cough was about gone, and he expressed himself as feeling "first-rate." From April 27th to May 6th no treatments were given. On May 5th the hæmorrhage recurred, and the cough and expectoration began to increase. During the week following he frequently spat "chunks of blood," and the sputa were not free from blood until the 16th. On the 26th, his weight was 126¾ pounds. A brief period of improvement succeeded, but during the summer he steadily lost ground. He now complains a good deal of stitch-pains in the left side; cough is quite troublesome; appetite variable; looks pale; feels weak; occasionally has a night-sweat. A considerable hæmorrhage occurred on the 20th of September. Physical examinations made in July and August, showed increasing disease in the left lung, which now involves the entire upper lobe. The respiratory murmurs over the lower lobe is very feeble. Weight, September 20th, 123 pounds; temperature 99.4°; pulse 108. Expansion two inches. This case is classed under "temporary improvement".

Medicaments for inhalation have been varied to suit individual cases, but iodine has been most generally employed.

A CASE OF POISONING WITH THE OIL OF GAULTHERIA.[1]

BY J. G. PINKHAM, M.D., OF LYNN.

THE subject of this report was a young woman who had been married three weeks, and was three months advanced in pregnancy. On March 1st, at 9 P. M., she took, by advice of a friend, one ounce of the oil of gaultheria, for the purpose, as was supposed, of procuring an abortion. Soon after taking the drug, she complained of a bad feeling in the head and of other unpleasant symptoms. At 11 P. M., a neighboring physician was called in. At this time, the prominent symptoms were profuse perspiration, pain in the abdomen, frequent and painful micturition, and purging. Mustard was given as an emetic, with no result, except the vomiting of a little white froth. Towards morning a convulsion occurred, after which the feet remained fixed in a state of flexion. At 7 A. M., March 2d, Dr. C. A. Lovejoy, to whom I am indebted for the clinical history of the case, was summoned to take charge of it. He found the patient tossing about in the bed, and apparently suffering from severe pain. She was totally insensible to light, and nearly so to sounds. The body was bathed in perspiration, face flushed, respiration rapid, pulse extremely feeble. Shortly after the Doctor's arrival, a large amount of urine was passed involuntarily. The treatment was stimulating. At 10 A. M., the symptoms remained the same, except that the pulse was stronger. A short time before noon, she again passed a large quantity of urine in bed. Death occurred, without return of consciousness, at 12 M., fifteen hours after the ingestion of the poison.

Autopsy at 10 A. M., March 3d, twenty-two hours after death, Drs. Lovejoy and Sheldon assisting. There was no rigor mortis, except a slight degree of it in the jaw and left knee. The feet were drawn into the position of talipes equinus. The fingers and toes were flexed, and the thumbs drawn into the palms of the hands; when these members were straightened, they resumed their flexed position at once after the extending force was removed. Corneæ hazy. Pupils half dilated. Buccal mucosa pale. The edge of the tongue appeared to have been bitten. Abdomen flat; recti relaxed. Breasts full; areolæ distinct; on pressure, a fluid like colostrum exuded. On section of the body, the blood was found to be very black, and, with the exception of a few small clots in the large veins, to be everywhere fluid. The liver, spleen, and the posterior portions of the lungs were engorged with black blood.

Externally, and on section, the kidneys appeared to be deeply congested, but otherwise healthy. The pericardial sac contained about two drachms of fluid. Heart healthy. The uterus was dark posteriorly near the fundus; it was enlarged to about the size attained at the end of the third month of gestation. The right ovary contained a corpus luteum of pregnancy. The mucous membrane of the stomach, and that of the duodenum for a distance of four inches from the pylorus, were intensely congested; below this point in the small intestines, the evidences of irritation gradually diminished. The contents of the stomach and intestines had a strong odor of checkerberry. The brain and all other organs examined were normal in structure.

To sum up the facts in this case, we have, as the result of taking one ounce of the oil of checkerberry, distress in the head, profuse perspiration, pain in the stomach and bowels, purging, diuresis, with frequent painful, and at the last, involuntary micturition, abolition of sight and hearing, general convulsions, tonic spasms of the flexors of hands and feet, great depression of the heart's action, rapid respiration, and death in fifteen hours. *Post-mortem*, we find persistent spasm of hands and feet, great irritation of the gastro-intesinal mucosa, a black, fluid state of the blood, and congested kidneys.

The oil of checkerberry (gaultheria procumbens) is said to be composed of methyl-salicylate nine parts, and a hydro-carbon called gaultherilene, one part. I am not aware that these substances have been separately studied, but it is highly probable that the active properties of the drug are due to the methyl-salicylate, which is one of the series of methylic ethers, and would seem entitled, from this fact alone, to be ranked among the poisons. It may be obtained artificially by distilling a mixture of two parts of crystallized salicylic acid, two parts of anhydrous wood spirit, and one part of oil of vitriol. When obtained in this way, it has the characteristic appearance and odor of the oil of checkerberry procured by distillation from the plant — a fact which would add still further to the probability that, in considering these cases of poisoning, methyl-salicylate is the substance with which we have to deal. Poisoning with the oil of checkerberry appears to have been rare. Beck[2] speaks of a fatal case that occurred in New York in 1832. Toxic effects have been known to follow large doses of an infusion prepared from the leaves of the plant. But, in the limited research which I have been able to make, I have found detailed reports of only three cases of poisoning with the oil.

The first case was reported by Dr. Gallaher[3]: A boy, aged nine, took a tablespoonful of the drug just

[1] Read before the Massachusetts Medico-Legal Society, February 2, 1887.

[2] Medical Jurisprudence, Vol. II, p. 942

[3] Philadelphia Medical Examiner, 1852, n. s. Vol. VIII, p. 347, et seq.

before supper. Symptoms: early and persistent vomiting, purging, pain and tenderness in epigastric and hypochondriac regions, a hot skin, rapid pulse (125), slow, laborious, and loud respiration, inordinate appetite for food, thirst, increased pulsation of carotids, great dulness of hearing, a parched and swollen mouth. There was no delirium or stupor. The eyes were red, but the pupils remained natural. Recovery took place after treatment with small doses of calomel, blood-letting, and blisters over stomach and bowels.

The next case was reported by Dr. Allan McLane Hamilton.[4] The patient was an adult female, and the amount taken was one-half ounce. The symptoms, as described by the doctor, who saw her an hour after she had taken the poison, were dizziness, drowsiness, marked delirium, pain in the head, noises in the ears, like the buzzing of bees, disturbed vision, hallucinations, left hemiparesis, a hot head, strong pulsation of temporal arteries and veins, contracted, then dilated pupils, cold extremities, rapid and labored respiration, restlessness, salivation. There were no marked gastric or intestinal symptoms. The patient had a strong inclination to sleep, and could only be kept awake by slapping, the use of galvanism, etc. The case ended in recovery.

The third case was reported by Dr. Jewett.[5] The patient was an intemperate man, aged fifty-five, who took by mistake, at 12 M., one-half ounce, as nearly as could be ascertained, of the oil. The symptoms, which began very soon, were severe pain in the stomach and bowels, burning heat, intolerable thirst, vomiting and purging, perspiration, labored respiration, gradually failing sight. The hearing remained unimpaired, and the mind clear until 4.45 P. M., when delirium set in, followed by complete unconsciousness at 5 P. M. As sight failed, things at first looked pale green, then dark green, then black. At 4 P. M., sight was lost. The case ended in death. This patient took, of his own accord, some infusion of tobacco to produce vomiting, a circumstance which doubtless modified the symptoms, and may have contributed to the fatal result.

These cases prove that the oil of gaultheria, when taken internally, is highly irritant to the gastro-intestinal mucous membrane, and that it exerts a powerful influence upon the nerve-centres. As a poison, it must, therefore, be classed among the narcotico-irritants. As a remedy, it has been prescribed in rheumatism. The "National Dispensatory" and Wood's "Therapeutics" speak of the use of the plant as an emmenagogue. It is doubtless upon this theory of its action that its reputation as an abortifacient, like that of other aromatics, is based. It probably has no just claim to this distinction; but the oil certainly resembles the abortifacients in this, that when taken in decided doses, it is pretty sure to kill the mother. It is stated in the "United States Dispensatory" that the oil of gaultheria is sometimes adulterated with chloroform. If this is so, it is possible that some of the neurotic symptoms ascribed to it in the cases which have been reported may have been due to this impurity.

— Two new books of popular nature are announced from Dr. S. Weir Mitchell: one, a volume of essays entitled "Doctor and Patient," and intended especially for women; the other a novel, "In the Far West."

FOUR CASES OF PENETRATING WOUNDS OF THE KNEE-JOINT TREATED AT THE BOSTON CITY HOSPITAL.

REPORTED BY OLIVER H. HOWE, M.D., *Formerly House-Surgeon.*

Case I. Delayed Antiseptic Treatment. Prolonged Suppuration. Recovery.

J. F. B., twenty-one years old and a carpenter, one day stuck a chisel two inches wide, into his left knee. He walked a short distance afterwards, but while going up stairs, felt something snap and almost fainted. Said that pus came from the knee the next day. No chills. General health excellent. Drank some beer. Was treated at home for three days with cold-water dressing and ham-splint.

Three days after the injury he was brought to the hospital and admitted to Dr. Gay's service. The left knee showed an incised wound about an inch and a half long just above the upper edge of the patella. Fluctuation about joint, with patella floating: also an area of diffused redness about the wound. On pressure, much thin purulent fluid exuded from the cut. The knee was very tender. Temperature, 102.3°; pulse 100.

Six leeches were applied to the knee and followed by a poultice. The joint was irrigated daily with 1 to 40 carbolic solution.

Third day. Suppuration rather less; dressing of iodoform gauze applied.

Ninth day. More suppuration; knee-joint distended. Temperature was rising gradually at night, tongue had heavy, whitish coat; appetite poor. Required a grain of opium every six hours. Temperature rose to 103.8°.

Twelfth day. Pus was burrowing up the thigh. Pressure six inches above the knee brought copious discharge from the tubes; redness extended half-way up the thigh. Pain increased until on the 17th day Dr. Gay enlarged the wound above the knee, under ether. The finger readily passed into the joint. Counter-openings at inner and outer sides of joint were made and a drainage-tube passed directly through the joint cavity.

Twentieth day. Pus which had been pocketing in the thigh was evacuated by pressure.

Twenty-first day. Temperature lower; felt better; less suppuration.

Twenty-second day. Incision under ether at inner side of knee, evacuating three or four ounces of pus.

Twenty-fourth day. Pus cavities seemed to be completely drained. Temperature had fallen to normal.

From this time the patient steadily improved. Three small pockets of pus were incised at different times; the tubes were shortened and finally dispensed with. Opiates became unnecessary. The tubes were wholly removed and splint omitted on the seventy-second day. After the latter time, the wounds soon became superficial and the swelling disappeared.

Eighty-eighth day. After having sat up for several days, patient walked with crutches. Could bear considerable weight on the foot without pain. Temperature since forty-fifth day had been practically normal.

Ninety-sixth day. Motion of 15° in knee-joint.

One-hundred-and-second day. Walked readily with a cane; could bend knee at an angle of about 30° without pain. Had gained much flesh and was in excellent physical condition. Discharged well from hospital.

CASE II. Treatment neglected for Eight Days. Extensive Suppuration. Pyæmia (?). Death.

R. J. M., a boy, twelve years of age, was brought to the hospital, January 7, 1887, and assigned to the service of Dr. Bradford. His story was as follows: Eight days before entrance, while using a draw-shave, it slipped from his hand, fell and struck his left knee, making a transverse cut just above the patella. His mother applied strips of adhesive plaster to the wound and he remained in bed for three days. At the end of this time, feeling no pain, he got up, dressed and walked about the house for a day. Having considerable pain in the knee that night, his mother, by advice of the neighbors, applied a flaxseed poultice. The pain gradually increased, until, on the eighth day, a physician was called in, who advised immediate removal to the hospital.

At the time of entrance, an incised wound an inch long was seen just above and to the outer side of the left patella. Pus was oozing from the wound and about it was an area of diffused redness rather larger than a silver dollar. The whole knee was swollen, painful and very tender. Temperature 103.2°; pulse 100.

A poultice was applied to the knee and quinine and brandy were given at intervals in moderate doses. The next day the patient was etherized, the knee examined and the wound was found to communicate with the knee-joint. Free incisions were then made to drain the joint cavity; two at the outer side and one at the inner; also one in front of, and below the patella. Several ounces of pus came away from the openings at the inner side. The joint was washed out by irrigation with corrosive-sublimate solution (1 to 5000) and drainage-tubes inserted. The wound was then dressed antiseptically with iodoform and gauze and an extension by weight (2 lbs.) applied to keep the limb steady.

The following day (the second after entrance) the boy was much more comfortable and the temperature rose only to 101.4°. The dressing soaked through with discharge and was renewed. The third day after entrance, much pus was found about the joint, the boy seemed weaker and his stimulant was increased.

On the evening of the fourth day the temperature rose to 104.8°, but with antipyrin (grs. xxx) it fell to 101°. On the sixth day, there was very little pus on the dressing, but pain and tenderness were found on the inner side of the left ankle and also in the right elbow. No fluctuation detected at either of these places.

On the eighth day the temperature was taken hourly. Between the hours of two and three P. M., it fell from 104° to 103.4°; at five P. M. it was 106°. At the dressing, no pocketing of pus was found and the granulations looked well. The patient's manner was peevish and fretful and growing constantly more so. The heart was carefully examined at the time of entrance and found negative; on the eighth day a systolic murmur was heard at the apex.

On the ninth day the temperature showed two slight remissions and at six P. M. was 105°. The patient was much weaker and had become delirious.

On the afternoon of the tenth day the temperature fell two degrees and regained its former elevation in six hours. The pulse was between 160 and 170. The patient gradually became weaker and died just before midnight on the tenth day after entrance, and eighteen days after the receipt of the injury. No eruption on the skin was seen at any time and no signs in the lungs were detected. No autopsy could be obtained.

CASE III. Prompt Antiseptic Treatment. Union by First Intention.

W. H. O., forty years of age, an expressman, was lifting a stove out of a wagon. The stove, which was said to weigh about 600 lbs., suddenly slipped and its sharp lower edge struck heavily across his right thigh just above the knee, making a sort of incised wound.

The man was brought at once to the hospital and admitted to the service of Dr. Gay. The right thigh showed on its anterior and outer aspect, just above the knee-joint, an incised wound six inches long. Through this wound, the finger, introduced downward, readily entered the joint cavity.

The wound and cavity of the joint were irrigated with carbolic solution 1 to 40, and a drainage-tube inserted at the lower angle of the wound. The wound was then closed with silk sutures, a dressing of iodoform gauze applied and the limb placed on a ham-splint. No ether was given.

Three days later the wound was redressed for the first time and found to be in excellent condition; no redness or suppuration and only moderate swelling.

Sixth day. Wound had healed by first intention, except where drainage-tube was. Stitches removed.

Tenth day. A few small grayish shreds had come away through drainage-tube, but there was no sign of suppuration. No swelling or tenderness about the knee-joint.

The tube had been shortened several times and was removed on the seventeenth day. On the nineteenth day the antiseptic dressing was omitted. On the twenty-fourth day, all dressing was omitted over knee. Ham-splint remained on. The temperature had never risen above 100.5°.

Thirty-first day. Sat up in chair, but no bending of knee was allowed.

Thirty-fifth day. Union seemed perfect. Could move knee considerably without pain, but had not walked yet. All seemed firm and well. Went out from hospital without any splint and was to remain quiet at home a little longer.

CASE IV. Prompt Antiseptic Treatment. Union by First Intention.

R. M., a carpenter, fifty-four years of age, was hewing timber on July 27, 1886. His broad-axe suddenly glanced and struck the outer side of his left knee, causing a wound and profuse hæmorrhage. He at once bound his handkerchief tightly about the knee, using pieces of his coat-lining to reinforce it. Twenty minutes later, Dr. David E. Baker of Newton Lower Falls, who had been summoned, found him sitting on a pile of boards out-of-doors, supporting his knee with both hands. On removing the handkerchief, a wound about three inches long, close to and parallel with the outer edge of the patella, was seen. There was no external bleeding, but the joint was found to be full of blood and clots. While tying several small arteries, which were bleeding, Dr. Baker sent to the nearest house (about one-eighth of a mile away), for boiling water. Cooling the water until the patient could tolerate the heat, he washed out the joint cavity by means of a Davidson's syringe. While doing this, he found that a crescentic flap of cartilage three-

fourths of an inch long, had been turned up by the axe from the articular surface of the femur. Pushing this into place, he blew iodoform into the joint and the external wound, sutured the capsular ligament with fine, untwisted silk, and the external wound with coarser silk, applied pads of absorbent cotton and bandaged the joint snugly. Having thus treated the patient, he drove him in his buggy to the nearest railroad station, whence he was taken to the Boston City Hospital, where he arrived about four hours after the accident. He was assigned to the service of Dr. Bolles.

After reaching the hospital, a ham-splint was added to the dressing. The next day, on removal of the dressing, a little clear fluid was seen to ooze from between the edges of the wound, at one end. Pressure caused much more of this fluid to escape. The joint-cavity was then irrigated with carbolic-acid solution (1 to 40), the wound dressed with iodoform gauze and the splint re-applied.

The third day after entrance, the dressing was again removed and considerable colorless fluid pressed out. A little redness was seen about a part of the wound, but no signs of pus and there was no pain.

On the fifth day after entrance, the joint was irrigated with corrosive-sublimate solution (1 to 3000); this was repeated on the ninth, sixteenth and twenty-third days, respectively. No synovial fluid was seen after the fifth day and no pus was seen at any time. The patient had almost no pain and there was no swelling or redness, except that already mentioned, which quickly subsided.

The highest point reached by the temperature was 100.4°, on the day of entrance. After the eighth day it was normal. The pulse was never more rapid than 85.

On the twenty-ninth day, the wound was entirely healed; the dressing was then omitted, but the splint was kept on. On the thirtieth day, the patient was allowed to walk about with crutches and on the thirty-third day he left the hospital. At time of his discharge from the hospital, he could bend the knee slightly without pain and had no swelling about the joint. He wore home a ham-splint with a bandage and slight compression over the knee. One month after leaving the hospital (about two months after the injury), he was seen again and had completely recovered the use of the joint and resumed his occupation.

These four cases well illustrate the different results following the use of careless and inadequate measures (or no measures at all), and those obtained by the prompt use of thorough antiseptic treatment. This difference is especially well shown in case of a wound of a large lymph cavity, like the knee-joint. The far-reaching and destructive effect of absorption of infectious or unclean material is strikingly shown in Cases I and II.

The injury in all these cases, was almost identical. Three of the wounds were made with sharp, cutting instruments; the edge of the stove, although less sharp, produced in effect, an incised wound. The injuries in the two cases which rapidly got well under antiseptic treatment were the more severe of the four. Of the two cases which had union by first intention, one was able to leave the hospital in thirty-three days; the other in thirty-five days, while the one which recovered after suppuration, required one hundred and two days to reach the same result. The case which was neglected for eight days died in eighteen days from the time of the injury. In the two cases which were antiseptic throughout, the highest point reached by the temperature in either case was 100.5°; the constitutional conditions were at a corresponding degree of comfort.

Much care was used to preserve immobility of the limb during the whole process of repair. In Case III, the dressing was so arranged that the ham-splint was never disturbed when the wound was dressed.

These cases certainly show that early treatment is of the utmost importance; for no amount of later antiseptic treatment can wholly neutralize a bad beginning. Dr. Baker's treatment was unique and the promptness and skill, with which he carried it out, are worthy of imitation.

REPORT ON DISEASES OF CHILDREN.

BY T. M. ROTCH, M.D.

HEPATIC CIRRHOSIS.

During the past year cirrhosis of the liver, as it occurs in children, has been made the subject of especial study by Dr. P. Laure, of Lyons, and by Dr. R. P. Howard, of Montreal. The former investigator has published the results of his personal observations on five cases which came under his care at the Charité, in the April number of the *Revue Mensuelle des Maladies de L'Enfance*. He speaks especially of the importance of prophylaxis in regard to the use of alcohol and also in the dissemination of the contagious diseases, for he believes that although the hepatic lesions accompanying these diseases are usually transitory, yet that in certain cases they may become the starting point of a real cirrhosis: he also considers that cirrhosis in children is of more frequent occurrence than is usually conceded, and that quite a number of cases are mistaken for tubercular peritonitis. The principal symptoms of the disease are icterus in the beginning, and later, ascites.

Dr. Howard has made a more extended study not only of his own cases but those of others and has presented his views on the subject and an analysis of sixty-three cases in the *American Journal of Medical Sciences* for October, 1887. He prefaces his remarks by stating that the disease is a rare one in children and that in speaking of cirrhosis he means to describe a diffuse development of the connective tissue of the liver without reference to the question of the inflammatory or the simple hypertrophic nature of that development, the word interstitial hepatitis being employed as synonymous with hepatic cirrhosis.

The following is an abstract of his article: The known conditions in the human subject under which interstitial hepatitis occurs, may be classified as follows:

(1) Tonic or irritating substances entering the blood (*a*) alcohol, (*b*) syphilitic virus, (*c*) malaria, (*d*) probably, but rarely lithic acid, (*e*) blood pigment in diabetes.

(2) Chronic congestion of the hepatic vein, as in valvular and pulmonary diseases and in those rare affections, obstruction or obliteration of the hepatic veins or of the inferior vena cava above the entrance of the hepatic vein.

(3) Adhesive inflammation of the portal vein especially the syphilitic variety.

(4) Extension of the inflammation to the interstitial tissue of the liver in chronic peritonitis and in perihepatitis.

(5) Obstruction of the bile ducts, whether from congenital defects (absence of common duct) or from acquired disease (tumors, gall-stones or experiment ligatures).

(6) In association with tubercular disease, especially of the lungs.

(7) As part of a general tendency to new formation or hypertrophy of connective tissue in the system, the so-called fibroid diathesis.

The author then compares with these known causes sixty-three cases of cirrhosis of the liver in children up to the age of puberty, excluding any cases of young adults and cases due to congenital defects of the bile ducts. His analysis resulted as follows: In the first place the above mentioned conditions were alleged to be present in but thirty out of the sixty-three cases, leaving over one-half of these to be accounted for in some other way.

(1) The ordinary cause of the disease in adults, the excessive use of alcohol, was found in only ten of these cases in children; its absence was noted forty-seven times and no mention was made of it in six cases. (2) An heredito-syphilitic origin was found in seven cases, the cirrhosis existing at birth in all but one; the absence of a syphilitic causation was affirmed in twenty-nine cases and no mention of it was made in thirty cases. In three of the syphilitic cases the virus set up an adhesive peripylephlebitis which terminated in a diffuse interstitial hepatitis, and these are the only instances in the whole number of cases of hepatic cirrhosis in children in which adhesive inflammation of the portal vein was the starting-point of the process. (3) Venous congestion of the liver a not infrequent factor in the production of cirrhosis in the adult, existed in but a solitary case. (4) The lithic-acid diathesis is not once mentioned as being present in these cases and the same is true of malaria; the absence of the latter, however, is only affirmed seven times; it may often have been overlooked. (5) In a single case the existence of a wide-spread false membrane in all parts of the abdomen and a complete envelope of it enclosing the liver, suggests that a peritonitis may have extended to the capsule of the liver and excited the interstitial hepatitis. In another case there were numerous adhesions between the liver and surrounding parts, but no general peritonitis. (6) The association of hepatic cirrhosis with tuberculous disease occurred in seven of these cases, about the same proportion as that in which cirrhosis and syphilis were co-existent.

In only six of the fifty-seven cases of non-syphilitic cirrhosis of the liver, omitting those in which the liver and spleen but no third organ had undergone cirrhotic changes, could it be shown that the hepatic cirrhosis was the outcome of a general tendency of the system to fibrosis, and in only one of them was found such a thickening of the walls of the blood-vessels, as would justify the theory that an arterio-capillary fibrosis was the source of the hepatic cirrhosis, at least in children. It is, however, to be borne in mind that the condition of the vascular system has probably not been investigated often in this affection in childhood.

In twenty-four of the fifty-seven cases of the non-syphilitic group, the spleen was abnormal.

The cause then having been determined in only about half of the cases, Dr. Howard takes up the question of the etiology of the remaining half, and he first refers to the suggestions of previous writers on this subject, such as Budd, who supposed that there "might be other substances among the immense variety of matters taken into the stomach or among the products of faulty digestion, which on being absorbed into the portal blood, cause, like alcohol, adhesive inflammation of the liver." Botkin also advanced the hypothesis that the acute infectious diseases might originate chronic inflammatory processes in the parenchymatous organs, because he had found beginning interstitial inflammation of the liver, in persons dying of cholera and of typhoid fever, while Klein described an acute interstitial hepatitis as being present in eight cases of scarlet fever which he had examined. Again referring to the analysis of the thirty-eight cases of cirrhosis of the liver which could not be referred to any of the established causes of that affection the author finds that in ten instances the cirrhosis was preceded by the following acute infectious diseases, with a larger or shorter interval: that is, scarlet fever twice, measles and scarlet fever once, measles alone four times, measles and pertussis three times; of the remaining twenty-eight cases antecedent acute infectious diseases did not occur in three and are not mentioned as occurring in twenty-five. Even if it be granted that, in the nine cases in which acute infectious fevers did precede the hepatic cirrhosis, they really originated the interstitial lesion (a supposition which can hardly be accepted after we consider the great frequency of these infectious diseases in childhood without a resulting cirrhosis), there remain three in which those diseases had not occurred, and twenty-five in which they were not mentioned, and for such examples of hepatic cirrhosis, Howard considers Budd's explanation to be highly probable, indeed it is more especially in childhood, when alcohol as a cause of hepatic cirrhosis, can be, in a large proportion of cases, safely ignored, that we feel disposed to accept the view that the products of faulty digestion and certain stimulating kinds of food conveyed to the liver, set up interstitial hepatitis, although it is impossible to bring much evidence in favor of this mode of causation, owing to the absence of information as to the habits, diet, etc., of the cases which have so far been reported.

The age at which cirrhosis of the liver occurred in the 56 non-syphilitic cases (omitting two where the age was not stated) was as follows:

Under 3½ years.		5 to 8½ years.		9 to 13 years.		14 to 18 years.	
Birth	1	5 years	4	9 years	5	14 years	1
3 months.	1	5½ "	1	10 "	7	15 "	1
17 "	2	6 "	2	11 "	7	18 "	1
20 "	1	7 "	3	12 "	5		
2 years	1	8 "	2	13 "	4		
3 "	2	8½ "	1				
3½ "	2						
Total,	10	Total,	13	Total,	28	Total,	3

The above table shows that the greatest liability in childhood to hepatic cirrhosis is from the ninth to the twelfth year, inclusive. As regards sex, there were 35 males, 17 females, and in 4 cases the sex was not stated. Regarding the character of the cirrhosis in these 56 non-syphilitic cases, the atrophic form oc-

curred in 19, the hypertrophic in 13, in 6 the liver was of normal size, in 16 this point is not mentioned, and in 2 the patients were still living. The author finds that the symptoms of hepatic cirrhosis in children are identically those of the disease in the adult. In 10 out of 52 cases uncomplicated by other affections which might produce pyrexia, cirrhosis was associated with fever; that is, in 19.2 per cent. In the 56 non-syphilitic cases, ascites existed in 34; it was absent in 8, and not mentioned in 14. Icterus was present in 23 cases, absent in 12, and not mentioned in 21. It was present in the hypertrophic form in 70 per cent. of the cases, and in the atrophic form in 71.4 per cent. The fatal issue of hepatic cirrhosis in children is brought about in many different ways, but three are especially frequent: namely, by toxæmia or certain disturbances of the nervous system, by peritonitis, and by asthenia, in the production of which hæmorrhage plays an important *rôle*. The toxæmic symptoms in these children were, more especially, violent fits of crying, and frequently, of screaming, delirium, dilated pupils, stupor, tremor, twitchings, clonic or tetanic convulsions, rigidity, coma, and hæmorrhages from the stomach, nose, intestines, or kidneys.

The summary made by the author from his analysis of these 63 cases of hepatic cirrhosis in children is as follows:

(1) That most of the established causes of the disease in adults occur also in children, more especially the use of alcohol, which was present in 15.8 per cent. of the whole number; syphilis, chiefly hereditary, present in 11 per cent.; tuberculous disease of other organs than the liver in 11 per cent.; also, but much less frequently than these, venous congestion of the liver, peritonitis, and a general tendency to connective-tissue formation in the system. (2) That syphilis occasionally tends to a diffuse interstitial hepatitis or cirrhosis by first inducing an adhesive inflammation of the portal vein. (3) That a general arterio-capillary fibrosis is not proved by these cases to be the usual, and probably not even a frequent cause of hepatic cirrhosis in childhood. (4) That more than half of the cases of hepatic cirrhosis in children do not appear to be produced by the above-mentioned well-established causes of that affection. (5) That there is some evidence that cirrhosis of the liver may be very exceptionally induced by the acute infectious diseases, cholera, typhoid fever, measles, and scarlet fever, but that proof of this is wanting. (6) That the habitual use of a stimulating diet, or the absorption of the products of faulty digestion, are probably fruitful sources of hepatic cirrhosis in children. (7) That it is in harmony with what is known of the causes of hepatic cirrhosis to believe that the bodies known as ptomaines may be capable of exciting a cirrhotic condition, and that investigation of this subject deserves attention. (8) That the period of childhood most liable to the disease is from the ninth to the fifteenth year, inclusive, but that it may be congenital, and may occur at any age after birth. (9) That it is twice as frequent in male children as in female. (10) That its symptoms are essentially the same in childhood as in adult life. (11) That it is frequently accompanied by pyrexia. (12) That ascites or icterus, and frequently both together, are of common occurrence in both the atrophic and hypertrophic forms. (13) That the group of symptoms which have been referred to cholæmia, or to cholosteræmia or to acoholia, and even, sometimes, to uræmia, frequently ushers in the fatal issue of hepatic cirrhosis in children.

GLIOMATOUS HYPERTROPHY OF THE PONS.

Prof. Henry Hun, of Albany, has lately published such a valuable report of a case of glioma in a child, and the disease is so rare in the literature of pediatrics, that an account of the case, as given by him in his reprint from the *Medical News*, will add much to our knowledge of differential diagnosis in cerebral disease — knowledge which is of special importance to those who are liable to be confronted by the complex nervous symptoms, simulating, at times, serious lesions, where, in reality, no such lesions exist, but are merely reflex manifestations of the extremely hypersensitive nervous organization of infancy and childhood.

Case. Steadily increasing incoördination of movements, bulbar paralysis, and general motor paresis. Glio-sarcoma of the pons varolii.

April 17, 1886. C. L., female, aged six. The father of the patient died a little more than a year after she was born, with symptoms of melancholia and dementia. An autopsy was held, of which no account can be obtained, excepting that the mother states that there was found "water on the brain and tumor of the brain." There have been many cases of nervous disease in the family of the father, but none in that of the mother. The patient has had a number of attacks of spasmodic croup, and, three years ago, had measles. For a number of years, her left leg has become tired easily, and for some time she wore a rubber strap on her left foot, which showed a tendency to turn in. Otherwise, she has been in excellent health till two months ago, when she had an attack of croup, followed by a cough. Every time she coughed she felt a severe pain in the top of her head, but at no other time had any pain in her head. About three weeks ago she began to walk badly, and seemed to have trouble in balancing herself when standing. Her mind is clear, her memory is good, and she is not in any way nervous. She has an excessive appetite, and has vomited a little at times. She is a well-nourished, intelligent girl, but has a vacant expression. Her speech is drawling. She keeps her mouth open most of the time, drools when eating, and has some difficulty in swallowing. Her head is drawn toward the right shoulder most of the time, especially when she makes any exertion.

She stands with her feet wide apart, and is careful not to lose her balance. When she walks, her right leg seems more rigid than her left, so that she takes freer and longer steps with her left leg, and consequently, in walking, she tends to walk in a circle, turning always towards the right. Her walk resembles that of a drunken person, being very unsteady, swaying and pitching, as if, every moment, she were about to fall. Her legs and arms are rather weak, and the movements of her arms, especially of the right, are very awkward, but she holds them in no fixed position. There is no disturbance of sensibility in any part of the face, body, or extremities, and she recognizes objects placed in her hands when her eyes are shut. Plantar reflexes normal; no ankle clonus; knee-jerk exaggerated, especially on the right side. On ophthalmoscopic examination, well-marked optic neuritis is found in both eyes. Urine contains neither albumen nor sugar.

May 21st. She has slowly, but steadily failed, and her legs and arms are weak. Her legs bend under her, and she can neither walk nor stand. Tactile, painful, and thermic sensibility is normal in all parts of the body. She is dull, but her intelligence seems intact, and she shows little, if any, loss of memory. Her articulation is indistinct, deglutition is difficult, uvula is raised very sluggishly, though equally, on both sides, and the movements of the tongue are sluggish, though it is protruded without deviation. The pulse is small, varying from 120 to 140. At times, when she is asleep, her respiration is very rapid and panting, but it is rather slow when she is awake. When asleep, her eyelids are partly open, and the eyeballs are turned outward; but when she is awake, the eyeballs at times turn slightly inward, so that she squints, although no paralysis of any of the ocular muscles can be detected.

June 4th. She has been decidedly better lately, and her articulation and deglutition have improved slightly. She is brighter, and can sit up without assistance, but cannot walk. Two days ago, a well-marked ankle clonus could be obtained in both feet during the whole day, which has not been present either before or since.

June 13th. During the past week, she has steadily and rapidly failed. On some days, the left arm and leg have appeared completely paralyzed, while, on other days, she would move them a very little. She has been able to neither walk, stand, or even hold up her head, which falls backward, forward, or to either side, according to the position in which she is held. Her hearing and cutaneous sensibility have remained unaffected, and her sight is but slightly impaired. Lately, she has given indication of having pain in the occipital region, and there has been a decided increase in the size of her head during the past week or ten days. She has had no convulsions. Her pulse has been small and feeble. This morning, her respiration was stertorous for a few hours, and then became normal. Her intelligence seemed clear until the very moment of her death, which took place quietly and suddenly this evening.

Autopsy twenty-four hours after death: head only examined. Bones of skull rather thin. Dura mater adherent only slightly to skull-cap. Increased amount of subarachnoid fluid. Cerebral convolutions flattened, and cerebral substance very œdematous. Corpus callosum is pressed upward, and is very soft and thin, and almost broken through. Great and uniform dilatation of both lateral ventricles, which are filled with fluid of normal appearance. No dilatation of third and fourth ventricles. Cerebellum normal.

The pons varolii, as seen both from the base of the brain and from the fourth ventricle, is greatly enlarged, being three or four times the normal size. On section, the whole pons is found to be replaced by a tumor, apparently a glioma, which preserves wonderfully the normal appearance of the part, so that it looks like a great hypertrophied pons. A little posterior to the middle of the pons, on the right side, is a focus of softening, spherical in shape, and about three-quarters of an inch in diameter. When hardened, a section of the pons at its largest point measured two and a half inches in width, and one and three-quarters inches in depth. The tumor seems to be confined pretty accurately to the pons, the crura cerebri and the medulla oblongata being but slightly enlarged. On microscopical examination, the nervous elements of the pons are found to be encroached upon, infiltrated, and, in some places, by a great accumulation of small cells. The prevailing character of these cells is spindle, although there is a considerable number of sphenoidal cells, both large and small. There is no considerable development of "spider-cells." Between the small, newly-formed cells there seems to be a delicate, newly-formed basement-membrane, independent of the neuroglia. There is also present a very great many newly-formed vessels full of blood. The proliferation of cells is not limited to the pons, nor is it circumscribed by any sharp line, but extends throughout the the whole extent of the crura cerebri and the medulla oblongata, being less abundant the farther the section is removed from the pons. In the anterior part of the crura cerebri, the roof of the aqueductus Sylvii seems to be the especial seat of the glioma. The wall of the canal is remarkably firm and well defined, except at its extremity, where it terminates in the softened tissue on the under surface of the crura cerebri.

Professor Hun then remarks that, in regard to the exact nature of the tumor in this case, the diffuse, infiltrating, rather than displacing, character of the growth, makes it resemble a glioma; while the form of the cells, the presence of a basement-membrane, and the absence of any considerable new development of spider-cells, is in favor of its being a sarcoma. Such tumors are sometimes called glio-sarcomata; but, in consideration of the remarkable way in which the normal (though hypertrophied) appearance of the pons is preserved in these tumors, it seemed to him to be better to call them by the name proposed by Kuemmel, "gliomatous hypertrophy of the pons."

ANTIFEBRIN IN THE FEBRILE DISEASES OF CHILDREN.[1]

The treatment of a number of diseases in children with antifebrin, and comprising, in all, fifty-three cases, gave the following results: The temperature began to decline in from ten to twenty minutes after the medicine was given, and continued steadily until it reached its lowest mark; then, after remaining at this point for a short time, it began to rise again. The rapidity with which the temperature declined seemed to depend not so much upon the size of the dose as upon the peculiarity of the child and of the disease. The general condition of the children was noticed to be affected favorably, a previously restless and fretful condition being followed by quiet and sleep. In several instances, severe symptoms connected with collapse were quickly relieved. Scarlatina and erysipelas were more rebellious to the antipyretic action of the drug than any of the other diseases in which it was used, the temperature falling only a few tenths of a degree.

In pneumonia, occurring as a complication of measles, and in croupous and lobular pneumonia, the antipyretic action was prompt and energetic. The pulse became fuller, its frequency being diminished, though not always in proportion to the decline of the temperature. The respiration became deeper and more quiet. The drug was given in the form of powder, and in doses of ten centigrammes to children three or four years old. To older children, twenty, thirty, or even fifty centigrammes, were given. Small doses usually sufficed for poorly-nourished chil-

[1] Hidowitz Centralbl. f. K., July 9, 1887. Arch. of Pediatrics, October, 1887.

dren, the action of the drug being much more energetic in these cases than in more robust children. As much as two grammes were given in the course of a day. Antifebrin never produced any perceptible effect on the duration of the disease. In some cases of pneumonia, its use was accompanied by profuse perspiration, with cyanosis of the face and the ends of the fingers.

ANTIPYRINE FOR FEBRILE CONDITIONS DURING DENTITION.[2]

The usefulness of antipyrine in infantile therapeutics is daily becoming greater, and its value in bronchopulmonary diseases of a febrile character has been shown in a number of cases. Dr. Clemente-Ferreira has also found the drug to be used with advantage in the febrile conditions which accompany the evolution of the teeth. It appears to have a perceptible sedative effect upon the nervous system. If the stomach is sensitive, it is desirable to give the drug by the rectum.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

OCTOBER 8, 1887, the President, DR. WILLIAM L. RICHARDSON, in the chair.

DR. C. ELLERY STEDMAN reported the following case of

SERIOUS COLLAPSE FOLLOWING LABOR INDUCED IN THE NINTH MONTH ON ACCOUNT OF ANTE-PARTUM HÆMORRHAGE.

Mrs. N., aged thirty-six, pregnant with her third child, had always had good health; her last period was January 14th, and she expected to be confined October 21st. October 4th, up to which date she had been perfectly well, hæmorrhage set in, soaking through more than a dozen napkins, and several folded sheets, with clots as well as liquid blood: this continued till Dr. Stedman saw her at 4 P. M. of the 5th, in place of the physician engaged to attend her who was ill, having seen her about noon of the day before, but who made no examination. Dr. Stedman found the os thick and soft, dilated to the size of a half-dollar; there were no pains, but a feeling of downward pressure which she had learned to recognize as a premonition of labor: there was no active hæmorrhage, but a slight leakage going on. It was thought best to induce labor, though her pulse was little affected by the bleeding, yet it was unknown what a second flow might end in. The child lay L. O. A.: on account of the mother's stoutness, the examining finger could not reach inside the os to ascertain the presence of placenta, without etherizing the patient and introducing the hand within the vulva. In this case ether was considered objectionable. A catheter without stylet was supposed to be guided into the uterus; but it probably doubled up on itself, for it failed to excite pains, and time was unnecessarily lost until a second catheter was introduced with stylet, and pains began in a short time. There was now apparently little or no blood lost. After a few strong, expulsive pains, a fine boy was born alive at 2 P. M. of the 6th, with not as much loss of blood as usual (twenty grains of choral had been given at one o'clock). A drachm of ergot was administered: the placenta was expressed in fifteen minutes, and all seemed going well, only mischief was feared because the pulse grew rapid. Half an hour after the birth, the patient suddenly exclaimed that she was weak, and collapsed utterly, although there was no bleeding and the uterus was firmly contracted. The usual remedies were employed, but for a long time she seemed unlikely to rally. The patient's face was livid; there was dyspnœa; she tried to tear open her night-gown, cried for air; the pulse irregular and hardly to be felt, indeed was altogether lost at times: the intelligence was undiminished.

There was little chance for, and no attempt at, auscultation, all the attendant's efforts being directed towards keeping the patient breathing. The most effectual stimulant proved to be a hot, weakly carbolized, intrauterine injection which was given about eight o'clock with signal benefit, and the patient grew quiet, the pulse although about 125, was to be felt, and she fell asleep.

Improvement went on until the third day, when she had a violent chill; the temperature reached 102,° the pulse 120: on the fourth day it was 103°. The lochia was offensive, (though the vagina on the first appearance of odor had been douched antiseptically) and on the evening of the fourth day, after the vagina had been washed out, Dr. S. Crowell (whose efficient assistance in this trying case was invaluable) at my request administered a carbolized intrauterine douche as hot as could be borne: an offensive odor came from under the bed-clothes as the douche was given; but the smell of carbolic-acid overpowered it in the bed-pan. The temperature immediately fell from 103° to 100.5° and the pulse from 120 to 112, and improvement and recovery followed: on tenth day she sat up.

Dr. Stedman called the case one of partial placenta prævia; but the only mark on the placenta was a thin margin of coagulated blood on a sixth part of its circumference, and he was unable to touch any presenting part of the afterbirth before or during labor.

Did the chloral play any part in causing collapse? Was it entirely shock? Would ether have lessened or prevented the shock?

Were the symptoms of collapse due to a forming thrombus of pulmonary artery or veins, as in a case of recovery from embolism reported by Dr. Stedman to this society several years ago, when he quoted Playfair's three or four cases of recovery, with his remark that "it will be readily understood why, in the presence of so sudden and awful an attack, symptoms have not been recorded with the accuracy of ordinary clinical observation"? Playfair has the fullest and best account of this accident of any writer whom Dr. Stedman had read.

Again, what was the fever owing to? All antiseptic precautions were strictly observed by the physicians: the nurse was an old-fashioned one, but faithful and devoted: the patient's husband was sure that she followed all orders. The catheters were supposed to be new, and were washed in the sublimate solution.

DR. MINOT thought that the collapse was hardly due to embolism, but rather to exhaustion from the previous hæmorrhage; as to ether in such cases, he had never regretted using it.

[2] Archiv. for Pediatrics, February, 1887.

DR. INGALLS also thought the collapse was probably due to exhaustion.

DR. REYNOLDS could see no objection to the use of chloral, and thought the symptoms were due to antecedent hæmorrhage; he agreed entirely with the reporter as to the importance of prompt delivery in such cases.

DR. ELLIOT inquired if there was any douching after labor, and if possibly air-embolism might not have been thus occasioned.

DR. STEDMAN said that a corrosive douche had been administered immediately after labor; but the idea of air-embolism had not occurred to him.

DR. STRONG had seen one case of death from embolism in a hospital patient. The symptoms were different, however, from those in the case reported: the patient was quiet, and complained only of lack of air; there was no violence, only sighing and tossing of the head.

DR. BLAKE agreed with the reporter regarding the advisability of prompt delivery when ante-partum hæmorrhage suggested the probability of placenta prævia. He also alluded to the case of partial placenta prævia complicating twin pregnancy in a primipara. As the hæmorrhage was considerable, he performed podalic version of the first baby, the second following soon after, and the patient making a good recovery.

THE PRESIDENT thought Dr. Blake's case one of great interest, especially on account of the success of version in a twin pregnancy. In Dr. Stedman's case he thought the collapse was due to shock and to the previous hæmorrhage.

INDUCTION OF PREMATURE LABOR.

DR. MINOT reported two cases. The first was that of a lady forty years old, primipara, six months pregnant. She had had swelling of the legs, albuminuria with casts and other threatening symptoms for ten days previously, and on May 25th had a convulsion, which was followed by several others. On the 27th she was somnolent; there was general cyanosis; lungs œdematous; pulse 132; respiration 48. The tongue was bitten. Under chloroform the os was dilated with the fingers, aided by a glove-stretcher, without much difficulty. The forceps were introduced by Dr. Gardner of Providence, and the patient was easily delivered. There was no hæmorrhage. The patient died the next day, but Dr. Minot could not learn the particulars of her death.

The other case was that of a primipara, twenty years old, seven months pregnant, under the care of Dr. Forsaith, of Weymouth. Throughout her pregnancy she had suffered much from vomiting, but had been up and about until within four or five days during which the vomiting had been incessant. Nutritive enemata had been given, but they could only be retained a short time. She had had but little sleep, and that only from morphia. She was greatly emaciated, much exhausted, and apparently in a condition of much danger. The pulse was at 128, and weak. The os was dilated by the fingers, aided by a placenta-forceps, and the child, which presented by the breech, was extracted without much difficulty by Dr. Forsaith. Although living before the operation it was dead when delivered. There was no hæmorrhage. The patient had a comfortable night, and did well. The vomiting ceased at once.

DR. STRONG asked the consideration of the Society upon a question of both ethical and practical importance; the duty of the attendant in the first subsequent pregnancy in uniparæ who have passed through the precedent pregnancy and confinement with great danger to life, and who have endured years of invalidism in consequence. The query was suggested by a case in his practice which had given him much anxiety during the past two months. The patient, now thirty years old, was of an extremely neurasthenic type. She was confined five years ago. Although of previous good health the course of her whole pregnancy was marked by extreme nausea and vomiting and general prostration with reflex nervous symptoms of all kinds, so that twice the induction of premature labor was urged; but neither patient nor husband would consent. The symptoms persisted until the end of pregnancy. The first few hours of labor were fairly well endured and then the patient suddenly passed into a state of collapse so complete that immediate emptying of the uterus was demanded and accomplished. The statement of the attendant, given in his own words, is: "She was the sickest patient I ever saw recover. I expected her to die every moment; but she did eventually rally. It was a month before she was able to move herself at all, and many more before she was out of bed. There was no septic element in the case, but total lack of any rallying power. I do not believe it will be possible for her to go through another confinement and live." This attendant is a man of extremely good judgment, perfectly free from prejudice or timidity, and upon his opinion great reliance may be placed. The patient was referred to the speaker about three years ago as a case of neurasthenia dependent upon uterine disease. She then presented the whole class of reflex nervous symptoms in their fullest development. It was felt that until the lacerations of the cervix and perineum were repaired and the hypertrophied uterus reduced and pessaries done away with but little could be done for the amelioration of these symptoms. These operations were performed by another physician, and it was about nine months later she again came under the speaker's care, having during that time tried many and various doctors. Her condition at this time was worse than ever before,—in bed all the time, with the darkened room and all the surroundings of the most pronounced neurasthenic. She was at once put upon thorough treatment, which occupied the whole winter and spring, with the most gratifying results. During the summer she walked each day several miles, attended to all her household duties, reëntered society (from which she had been absent for five years), and was practically well. She still had occasional nervous symptoms, but had learned to pay no heed to them. Two months ago she became pregnant and everything was changed. Her appetite vanished, nausea was constantly present, and vomiting once or twice daily. Her weight decreased twenty pounds. Her nervous symptoms returned in all their force, and now she is in nearly as bad condition as last fall, and is losing ground daily. The speaker asked the advice of the society, first, as to the propriety, or rather the justifiableness, of interfering with the pregnancy, and second, if it be advisable, what time should be chosen. Should it be delayed until the patient's life is actually in danger and then add to her risks those of induced premature labor? Or should heed be paid to the warnings of probable trouble

already given, and the uterus be emptied now by curetting? The responsibility of the decision is grave; for if any prognosis is to be made upon the history of the former pregnancy and confinement, the chances of a fatal result of a labor completed at term are very great. Nor are they much more hopeful for induced labor at a viable age of the fœtus; while if the condition of the patient demands interference at an earlier period, perhaps at the fourth or fifth month, the prognosis is still more serious. Ought not, also, the probability of saving months or years of suffering to the patient should she survive labor induced before time, weigh a little in determining *immediate* interference?

The speaker asked that in considering the case the members would not lose sight of the fact that it was *not* upon the propriety of abortion for nausea and vomiting of pregnancy that advice was sought, for these were but two of a multitude of nervous symptoms, nor were they of extraordinary severity; but to consider how narrowly the patient escaped with her life in the former confinement, and in how much more precarious a condition she now was from her five years of sickness. Of course, the question of abortion except as the last resort, could be considered only in one pregnancy.

The questions asked by Dr. Strong were fully discussed by the Society, and the unanimous opinion expressed that the pregnancy should be allowed to proceed, certainly until symptoms of gravity presented themselves. It would not necessarily follow, because the patient had a long and trying, even critical, convalescence from her first pregnancy and labor, that the same condition would obtain in her second. The opinion was expressed that such patients will usually endure a good deal, much more than would naturally be expected. The patient would require careful watching, and should be treated as a neurasthenic throughout her pregnancy and convalescence.

Dr. Strong, replying to the question of Dr. Richardson, as to the results he would expect to attain by carrying out either in this case or a similar one the regular treatment for neurasthenia, stated that he would not expect very favorable results. Success in treating neurasthenia depends upon removal of the exciting cause, whether it be external surroundings or some physical disease; as long as the patient has an evident basis for her sufferings, just so long will it be found impossible to convince her that any of them are not real and compel her to disregard them.

Dr. Ingalls reported the two following cases as probable instances of

HIGH TEMPERATURE FROM NERVOUS CAUSES.

January 11th. Woman, age 22, had had pain all day in frontal region, and she attributed it to a defective molar; pulse 80; temperature normal. In bed all next day with feeling of languor. Pulse and temperature normal. On the third day patient reported that she awoke at 3 or 4 o'clock in the morning, finding the bed-clothes had slipped from off her back, and that she was chilly for a while. The morning and evening pulse and temperature were: Pulse, 96, temperature, 106°. The following morning both were normal.

January 17th. A single lady, at about 30; at morning visit reported shiverings, or "creeps," all the night before, and that she feels poorly; the digestive organs are a little disturbed; pulse and temperature normal. On the next morning the patient said she was languid and wished not to be disturbed. Pulse, 96; temperature, 106°. There was no flush, eyes bright, skin pleasant to the touch. She felt well on the following day.

ESSEX NORTH DISTRICT MEDICAL SOCIETY.

AUGUSTUS STABLER, M.D., SECRETARY.

Annual Meeting, Lawrence, May 4, 1887.

The President, Dr. E. P. Hurd, introduced Dr. Gage, of Worcester, President of the Massachusetts Medical Society, who made a few well chosen remarks on the purposes and objects of the great Society he represents, and the implied duties of its members in aiding the public to distinguish that which is real in the practice of medicine, from that which is unreal. He also thought we should feel bound to advance the public good in the great field of sanitary science and preventive medicine.

Dr. Arthur Sweeney, of Lawrence, read a paper on

PUERPERAL ECLAMPSIA.

Dr. Lovejoy, of Haverhill, said he had seen four cases during the past year, in all of which he bled to the extent of about three half pints, and all recovered. He used other measures when indicated. He had seen a case that was apparently dead suddenly restored by dashing a handful of ether in her face. He knew of nothing more unsatisfactory than to look for lesions after death from convulsions.

Dr. Gage made some remarks on the indications in the prodromal stage. He thought the most important point was the quantity of urine passed, without regard to whether it is albuminous or not. The prognosis is always favorable in albuminuria of pregnancy if the patient continue to pass an abundant quantity of water, whereas he thinks there is always great danger of convulsions if the quantity be greatly reduced. This idea was not original with himself, but was borne out by his experience.

Dr. F. H. Allen, of Haverhill, had treated eleven cases of eclampsia without a death. His practice is to bleed the patient freely as soon as possible. He then gives two drops of croton oil, to be repeated in an hour if it does not operate in that time. He occasionally uses veratrum veride as an auxiliary to the above measures.

Dr. Morrill, of North Andover, reported eleven cases, with five deaths. He thought three of his cases would have been fatal under any treatment. He never bled, but relied chiefly upon ether anæsthesia and the rapid delivery of the child, if it be still in utero.

Dr. Huse, of Georgetown, would not employ bleeding unless positively indicated by the circulatory symptoms. He had seen marked benefit from pilocarpine, and is in the habit of reducing the activity of the reflexes by bromides and chloral in the rectum.

Dr. J. F. Croston, of Haverhill, read a paper on

LOCAL BOARDS OF HEALTH.

This paper was discussed by Dr. Lovejoy, of Haverhill, Dr. Cogswell, of Haverhill, and Drs. Abbott and Chamberlain, of Lawrence. The concurrent opinion of the essayist and those who followed

him seemed to be that the present difficulty does not lie in the lack of sanitary laws, in this Commonwealth at least, but in the ignorance of the public, and the election of improper or inefficient health officers. The duty of health officers and practitioners alike should be to educate public opinion up to the point of desiring the enforcement of sanitary laws and the observance of sanitary rules.

On invitation of DR. F. H. ALLEN the Society adjourned to meet at his house in Haverhill next October.

QUARTERLY MEETING, held at Haverhill, October 12, 1887, at the house of DR. F. H. ALLEN. The meeting was called to order by DR. E. P. HURD.

Resolutions, reported by committees, were adopted on the deaths of Dr. E. S. Yates and Dr. A. B. Magee, of Lawrence.

DR. R. B. ROOT, of Georgetown, read a paper on

THE ANALGESIC EFFECTS OF ANTIPYRINE.

He said that the results of clinical experience have demonstrated that its analgesic effects are as pronounced as those of morphia. In the cases in which he has used it he is more and more convinced that it is destined to supersede, in a great degree, opium and its salts, as he finds that it answers most of the indications of morphia without its unpleasant effects. He then gave an account of its chemistry and its physiological action, ending with its hypodermic use in France for the relief of pain. It was used in this manner in acute rheumatism, gout, neuralgia, angina pectoris, and asthmatic paroxisms. Also in hepatic and renal colic, and in these it is peculiarly applicable, since morphia locks up the secretions and probably retards the efforts of nature to bring about a cure. Antipyrine, M. Germain Sée insists, is entirely free from the above objections, and meets equally well all requirements for the relief of pain. Ungar, of Bonn, was led to try antipyrine in hemicrania, from the similarity of its action to salicylate of sodium.

The following cases fully corroborated the above remarks:

CASE I. Mrs. M., aged forty-five, a long sufferer from periodical attacks of ordinary "sick headaches" of great severity. The reader had employed bromides, chloral, tr. gelsemium, ergot, etc., with absolutely no benefit. Hypodermics of morphia relieved the pain, but were followed as usual by nausea, and lassitude. Antipyrine in ten-grain doses was completely successful. Half an hour after the first dose the pain was greatly relieved, and two or three powders, given an hour apart, permitted the patient to resume her housework, whereas, prior to the antipyrine treatment, two days and sometimes a week elapsed before she was able to leave her bed. The trouble recurs with its usual frequency, but antipyrine, given in the prodromal stage, wards off an attack.

CASE II. Miss F. Dysmenorrhœa pain was relieved by two powders of ten grains each.

CASE III. Mrs. P., aged forty, has been for years a sufferer from acute attacks of asthma of great severity. She has found indifferent relief from iodide of potash, tr. of lobelia, morphia, etc. During one of her recent attacks she complained of severe pain extending through her left side, including arm and leg, together, with a want of sensation in the affected side. Antipyrine, in ten-grain doses, relieved the pain, and with the subsidence of pain the asthmatic spasm passed away. She begged for more powders, and has since then warded off several attacks, and is very sure that the powders are of great benefit.

CASE IV. Mrs. W. fell on the sidewalk in Malden last March, sustaining a severe concussion of the hip, but no fracture could be detected by her attending physicians. Four months later she came under reader's care. Still using crutches, and complained of severe grinding nocturnal pain, extending from hip down the leg to below the knee. She had used liniments, massage, galvanism, etc., with no benefit. The reader ordered ten grains of antipyrine one hour before retiring, and she thought the next day that she had slept better than for a month previously.

CASE V. Mrs. C., aged seventy-five, suffering with membranous enteritis, complained of severe pain through the bowels. No tenderness on pressure was found, the pain being probably of neuralgic nature. As she did not tolerate morphia eight grains of antipyrine were given, with directions to repeat in two hours. The next day she expressed surprise that relief had come with but one powder.

CASE VI. Mr. C., September 6th, had acute rheumatism, affecting wrist and shoulder. Wrist swollen and red. Pulse 120; temperature 103°. Prescribed salicylate of sodium. Next day no improvement. Had passed a restless night; complained of pain in cardiac region. No valvular lesion. Antipyrine, ten grains every three hours, was ordered. Next day (8th), relieved of pain, though the joints still remained swollen. On the 9th, temperature 99°; pulse 90; swelling and redness nearly gone, and from that time convalescence was fully established.

Fränkel speaks very highly of the value of antipyrine in thirty-four cases of rheumatism, but acknowledges that in certain cases it cannot replace the salicylate. The reader would be inclined in another case to place the patient on the salicylates, and give antipyrine as an analgesic in addition. In every case of hemicrania the effect has been the same, though not in the same degree in every case. Some have had the pain entirely relieved, while with others the effect has been less marked. In one case of paralysis agitans, accompanied with dull pain in the forearm, there was no effect from the drug. No bad effects were noted from the remedy.

DR. M. A. JEWETT, of Danvers Lunatic Hospital, read a paper on

ILLUSIONS, HALLUCINATIONS, AND DELUSIONS.

A vote of thanks was passed to Dr. Jewett, and his paper requested for publication. In the discussion which followed, Dr. LOVEJOY, of Haverhill, related two cases of melancholia. The PRESIDENT asked DR. Jewett what proportion of insanity was due to modern spiritualism. DR. JEWETT replied that he had compiled no statistics on that point, but that there are always a number of such cases in the Danvers Asylum.

The PRESIDENT made some general remarks on the use of liquid vaseline as an excipient for hypodermic injections. He also related a case where sulphur ointment having failed to cure scabies he ordered naphthaline in linseed oil, ten per cent. Three inunctions were sufficient to effect a complete cure.

DR. CHENEY had used agnine on a burn with brilliant result.

The Society adjourned to meet in Haverhill the first Wednesday in January.

After adjournment DR. F. H. ALLEN entertained the members most hospitably at dinner.

NEW YORK STATE MEDICAL ASSOCIATION. FIFTH DISTRICT BRANCH.

SPECIAL meeting held at the Pavilion Hotel, Staten Island, November 15, 1887.

DR. ALFRED L. CARROLL, of New Brighton, made an address on

THE CLINICAL SIGNIFICANCE OF SPHYGMOGRAPHIC TRACINGS,

which was illustrated by a large number of examples.

He said that while the sphygmograph had not fulfilled all the sanguine promises which heralded its introduction, it was often of unquestionable clinical value. In cardiac disorders, it could never supersede the trained ear of the auscultator, but it might guide his examination, and, perhaps, modify his prognosis; while, in some instances, it might serve to localize an internal aneurism with a precision unattainable by any other means. It was well known that the intensity of a murmur at one of the valvular orifices was not invariably proportionate to the gravity of the lesion which induced it, and, except where the attending circumstances of aggravated cases aided our judgment, we were often uncertain in opinion. Here the sphygmograph might come to our relief with a mechanical measurement more accurate than our unassisted senses. Variations of vascular tension inappreciable by the most delicate and practised touch, degrees of obstruction or regurgitation unascertainable otherwise, were graphically recorded.

Too much, however, ought not to be expected from it; its tracings in a given form of disease were not identical and diacritic: they were only generically similar. It was not to be considered as a *means* of diagnosis, but, like other so-called "instruments of precision," as a frequently useful *aid* to diagnosis. Some years ago, in a paper published in the *New York Medical Journal*, he had endeavored to point out the extent and limitations of its utility; his present purpose was chiefly to call attention to a hitherto unnoticed source of misconception in regard to its registrations.

One of the principal drawbacks to the general recognition of the sphygmograph was the very ingenuity expended in its improvement, which had resulted in the invention and adoption of several different patterns of mechanism, each of which gave a tracing differing somewhat from those of the others with the same pulse. Hence, since the significance of every part of the hieroglyph depended on its conformity with or departure from a known normal standard, it was necessary for the more recondite indications of any sphygmogram to be told by what instrument it had been taken; and without this information and knowledge of the normal performance of the particular pattern of instrument employed, it was impossible to compare the results of different observations, and to profit by published records. To state an extreme example, the tracing of a healthy pulse by Pond's water sphygmograph would rouse a suspicion of cardiac hypertrophy, if supposed to have been made by Marey's or Mahomed's instrument, for the reason that in the former apparatus the needle-bearing lever, being detached from the motor-rod, was thrown loose by each pulsation, exaggerating the height of the systolic up-stroke, and of the repercussion and post-aortic waves; while, in the latter machines, the attached lever was withdrawn with the subsidence of the ventricular impulse, reducing the relative importance of these traits. An even greater exaggeration appeared to characterize the working of an exceedingly sensitive device invented by Mr. Edwards, of Buffalo, with which Dr. Carroll said he had had no personal experience, but which had been effectively employed by Dr. H. R. Hopkins, of that city, who has published numerous tracings taken with it. Dudgeon's sphygmograph, which, on account of its convenient portability, he had most used of late, gave a quite dissimilar normal tracing.

Less conspicuous, but still possibly misleading, variations existed between the tracings made by almost any two of the eight or nine patterns of sphygmographs in use by different observers, and although physical examination of the patient might correct misapprehensions in actual clinical work, the illustrations in many books and papers were thus robbed of much of their instructiveness. The rate of speed at which the slip was made to move would also materially modify the sphygmogram.

In view of these facts, and to establish sphygmography in the professional estimation which it merited, it was desirable, since it was not likely that any standard would be universally adopted, that all who published records of their work should not only mention the instrument which they employed, but give, in addition, for comparison, its tracing of a normal pulse.

Two of the tracings which Dr. Carroll exhibited were from patients suffering with exophthalmic goitre, and he said that he was not aware that any had ever been taken before in cases of this kind.

DR. J. W. S. GOULEY, of New York, said that Dr. Carroll had made a very strong plea for the clinical use of instruments of precision. He thought that the sphygmograph should be more generally employed, and should be in the hands of all practitioners.

DR. TRUAX, of New York, said that, on account of the uncertainty of the diagnosis indicated by the sphygmograph, he had given up the use of the instrument. Dr. Van Santvoord, who was attending physician to the institutions on Randall's Island, where there were hundreds of patients, and ample opportunity for testing it in all sorts of cases, had also found that, as a means of diagnosis, it was not to be relied upon.

DR. C. A. LEALE, of New York, said that after employing both Pond's and the French sphygmograph for a year, he gave up the use of the instrument, for the reason that the tracings compared so irregularly.

DR. GOULEY said that he thought the trouble was that physicians did not become sufficiently familiar with the use of such instruments, and, because they did not take the pains to do this, the results achieved were often unsatisfactory.

DR. W. C. WALSER, of Port Richmond, Staten Island, said that he had had the opportunity of seeing many of the cases, the sphygmographic tracings from which Dr. Carroll had exhibited, and that in all the instances in which autopsies had been made, the conditions noted corresponded with the results ob-

tained with the sphygmograph during life. The instrument, he thought, was also of much service in correcting our prognosis.

In closing the discussion, DR. CARROLL said that nearly all that had been said went to show that there was really some need of the remarks which he had made. In general, the sphygmograph was of service in correcting the diagnosis derived from other sources, as well as the prognosis. On account of the differences of various instruments, however, great care was necessary in its use. In the first place, it was of the utmost importance to study the tracings made by the normal pulse. In any departure from the normal, the difference in the sphygmographic tracing observed might be due either to central, medial, or peripheral modifications of the circulation. Hence, after the tracing had been made, it had to be interpreted, for the instrument did not make an absolute diagnosis. It did not make much difference which of the recognized instruments was used. Pond's water sphygmograph was exceedingly delicate, but was subject to some inconveniences. For general use, Dudgeon's was no doubt to be recommended as highly as any, on account of its portability and cheapness.

DR. WALSER read a paper on

CHRONIC PROGRESSIVE CARIES OF THE BONES OF THE FOOT, WITH CASES AND PRESENTATION OF A PATIENT.

In one of the two cases referred to, a female, the trouble had commenced at the age of ten months, and in the other, the patient presented, who was a male, at the age of twenty-two years. In both instances the origin of the trouble was very obscure, there being no syphilitic or other diathetic history, and the cases seemed to be of an almost unique character. The disease was apparently painless; in the case of the woman, in which it did not extend beyond the feet, completely so. In the man, who was presented, it also involved the tibia, and the only pain that he complained of was referred to this region.

DR. GOULEY said that the case presented appeared to be one of osteitis, with a certain amount of necrotic process, which had ended in metaplasis of the phalanges, the bone being changed to fibrous tissue. Some part of the metatarsus was still left.

DR. CARROLL said he would like to ask if there could be osteitis without pain. In the present case there was some pain, but in the other none. He wanted to know, also, what pathological condition preceded the metaplasis. The affection in these cases was one unknown to him.

DR. GOULEY said that, in his experience, he had not always found inflammation of the bone necessarily painful. In some instances which we had to recognize as inflammatory, all the usual phenomena belonging to the process of inflammation, as described in the books, were absent. While he had seen osteitis without pain, he had never known periostitis to be painless.

DR. S. H. BENTON, of Brooklyn, read a paper on

ANTITHERMICS IN NEURALGIC PAINS.

He said that his attention was first drawn to the analgesic properties of antipyrine in November, 1886, when he found that this agent, given in a temporary febrile condition, relieved headache in a case of two years' standing, in which a very large number of remedies had been tried in vain. After three months of treatment by antipyrine, given when indicated for pain, the headache, which was located in the right mastoid region, permanently disappeared. Soon afterwards, Dr. Benton tried antipyrine with excellent results in the case of his own wife. She was suffering from an attack of hemicrania, accompanied with a severe brachial neuralgia, from which she had frequently suffered for three or four years. Often, the pain in the arm and shoulder was so severe that hypodermic injections of morphia had to be used, which, at the best, gave only temporary relief, while the after-effects of the drug were so disagreeable that they were much dreaded. Since then, Dr. Benton had several times repeated the antipyrine in similar attacks, and always with gratifying results. While he could not say that she had been permanently relieved, it was true that the interval between the attacks had been much longer since he had begun the use of this agent, and she had not complained of the pain in the brachial plexus for two months. The dose of antipyrine employed in this case was twenty grains by the mouth.

The next case related was one of locomotor ataxia, in which eight grains of antifebrine were given every four hours, which gave more relief from pain than any other remedy which the patient, who was a lady forty-one years of age, had taken. Unfortunately, she did not live long enough to fairly test the utility of this class of remedies in her disease, and Dr. Benton said he was not sure that one would be justified in continuing the administration of such agents for an indefinite time, as would doubtless be necessary in the pains of locomotor ataxia. It was said, he continued, that the action of antifebrine and its analogues had a destructive action on the blood-corpuscles, as well as a tendency to produce fatty degeneration of the heart, and, if this were true, the continued use of these remedies would be pernicious medication. This theory, however, was new, and might be without foundation in fact. It was supposed that all these new antipyretics caused a reduction of temperature by their action on the thermic centres of the spinal cord; and, if this were true, their analgesic properties could doubtless also be ascribed to the same action. In the case of a lady otherwise in good health, who was subject to hysterical attacks, which were always followed by great præcordial distress, intercostal neuralgia, palpitation of the heart, and insomnia, antipyrine proved very satisfactory. The attacks were brought on by any kind of excitement, and were sure to recur, at least, once in every fortnight. For the last two months, she had been taking a teaspoonful of a mixture containing twenty grains of antipyrine to the fluid drachm every two or four hours, as required, whenever she began to feel nervous; and, during that time, she had not a single attack of hysteria or any of her old pains, and had been entirely relieved of insomnia. The use of the drug did not seem to give rise to any disagreeable symptoms.

His experience with antipyrine and antifebrine as analgesics, he said, had not been extensive, but he had used them enough to be convinced that they were of service in many cases; and he thought that if other observers obtained the good results from their use in this capacity as Dr. Lloyd had reported at the last meeting of the Kings County Medical Association, we had added to our armamentarium a class of remedies of inestimable worth. The disagreeable effects from the administration of these medicines in his own cases had been so infinitesimal, that they were not worth

noting. He said he gave them by the mouth most often, but had also given them hypodermically with satisfaction. Some writers had stated that the subcutaneous method of administration gave great distress at the point of insertion, but he had not observed this. It seemed to him that if the needle were inserted deeply, and the parts rolled freely under the thumb immediately after the withdrawal of the syringe, little or no pain would be experienced.

While in some cases, however, the administration of antipyretics as analgesics had seemed to have a desirable effect, and their superiority over other remedies used was demonstrated, he had given antipyrine and antifebrine in many more cases of painful troubles where he got no observable effect whatever. He thought it was only fair to give both sides of a question, as there must be rendered an unfavorable, as well as a favorable, report in regard to the action of all remedies. In three cases of sciatica of long standing, the patients derived no benefit whatever from antipyrine or antifebrine. In one other case, the pain seemed to be modified. In six cases of hemicrania at the menstrual period, very little, if any, effect was observed. In two cases of facial neuralgia no benefit was derived, and in one case of dysmenorrhœa in a young lady, there was the same negative result. In two cases of tabes dorsalis, some comfort was thought to be derived from their use. While, therefore, there was no doubt in his mind that, from his limited experience, antipyretics used as analgesics were of great service, and would grow in favor in the estimation of the profession, he thought that we must not expect too much from them. In many instances, they would disappoint us; but the same was true of quinine and many other of our standard drugs.

DR. P. BRYNBERG PORTER, of New York, said that he was of the same opinion as the writer of the paper, that while the class of agents referred to were no doubt useful in many instances of painful affections, many others would be found in which they were totally inefficient, and that we could not as yet dispense altogether with opium. In a case of neuralgic dysmenorrhœa in which he had used antipyrine hypodermically, no effect whatever was produced upon the pain, and he had been obliged to resort to morphia, as usual. The patient had complained of considerable more pain at the seat of insertion than when morphia was used, but this was of only temporary duration.

DR. JOHN P. GARRISH, of New York, said that he should consider it dangerous to give twenty grains of antipyrine every two hours, as Dr. Benton had reported doing in one of his cases.

DR. WALSER said that, being subject to migraine himself, he had tried ten grains of antipyrine every half-hour for the relief of an attack, but found that it had not the slighest remedial effect.

DR. T. W. ROCHESTER, of Brooklyn, said that he had observed that the same effects were not now reported from the use of antipyrine as at first, such as excessive sweating; and, as it was a patented article, he thought that possibly morphia might of late have been introduced into its composition, and the fact kept secret. There was another point that he had noticed in the reports of painful affections relieved by the use of antipyretics, and that was that the cases were nearly all in females, which he regarded as a somewhat significant fact.

The PRESIDENT, DR. EDWIN BARNES, of Dutchess County, said that in one typical case of migraine of exceptional severity under his charge, a single dose of twenty grains of antipyrine completely arrested the attack, if taken when the headache was just coming on.

DR. E. R. SQUIBB, of Brooklyn, said that no one knew the exact composition of these patented antipyretics. All these agents had been discovered in searching for substitutes for quinine, and they were all somewhat similar in composition, being built up on a radical of quinine.

DR. WILLIAM MCCOLLOM, of Brooklyn, thought it strange that the earlier writers on antipyrine and antifebrine said nothing about their hypnotic and analgesic properties. In his opinion, their position as remedies of this class could not as yet be positively determined.

DR. TRUAX said that in one case of dysmenorrhœa under his care, fifteen grains of antipyrine, given three times a day, seemed to have a very good effect; but, in several other similar cases in which he had tried it, it was of no use whatever.

DR. CARROLL gave a demonstration of a

DRESSING FOR GREENSTICK FRACTURE OF THE CLAVICLE.

The pressure over the fragment necessary for the successful treatment of this variety of fracture, was secured by Dr. Carroll by a compress held in position by the simple turns of an ordinary roller bandage passed in a figure-of-eight under the axillæ and over the shoulder near the seat of fracture.

DR. LEALE said he thought the dressing of Dr. Carroll a decided advance, since many good surgeons recommended converting a greenstick fracture of the clavicle into a complete one, in order to treat it more advantageously. It was all the more admirable on account of its extreme simplicity.

DR. ROCHESTER said that he had been in the habit of resorting to the plan just mentioned by Dr. Leale, but that in the future he would certainly use Dr. Carroll's dressing instead.

THE PRESIDENT presented a paper on

THE INDIVIDUALITY OF DISEASE,

which, on account of the lateness of the hour, was read simply by title. The concluding portion of the meeting was devoted to

MEMORIAL EXERCISES

in honor of three distinguished deceased Fellows, Drs. Alonzo Clark, James C. Hutchinson, and Jared Linsly, and biographical and eulogistic papers were read by Drs. John Shrady, S. T. Hubbard, Ellsworth Eliot, and J. W. S. Gouley.

— Dr. Zaldivar, formerly president of one of the South American republics, and also a practising ophthalmic surgeon, recently, while on a visit to Spain, performed several operations in the clinic of Dr Osio, before many of the leading medical men of Madrid.

— A congress of physicians and veterinaries having for its object the scientific study of tuberculosis in man and in the other animals, will meet at Paris in July, 1888, under the presidency of Professor Chauveau.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 8, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE PARASITIC ORIGIN OF CANCER.

THE success which has attended the investigation of the bacterial origin of tuberculosis, leprosy, glanders, and other diseases, and the progress made in the same direction both in hydrophobia and syphilis, has greatly strengthened the hope that light might also be shed upon the almost impenetrable darkness which still surrounds our knowledge of the etiology of cancer. A disease which affects so large a number of individuals, and for which no remedy beyond the uncertain resort to the knife has been found, and in face of which preventive medicine seems to be powerless, is one which the public may well demand that the medical profession should not fail to investigate anew in the light of modern science.

The attitude of so prominent a member of the profession as Sir James Paget towards this question has for many years directed the attention of English observers to the etiology of this disease; and many interesting facts have been elucidated, such as the predilection for certain localities, the greater frequency of the disease in certain countries, and the possibility of contagion in exceptional cases. In a recent address, he dwells upon the many points of resemblance between the class of diseases to which we have alluded and cancer. A tuberculous mass or a syphilitic gumma has, he thinks, more of the general character of a tumor than has a rodent ulcer or a cancer of the lip or tongue. The tendency of these to affect distant parts of the body bears a more striking resemblance still to the life-history of cancer.

It is probable therefore, that, as in these diseases there is a specific morbid material in the blood, a similar one exists in cancerous diseases. Sir James takes the ground, which, however, would hardly be accepted by the majority to-day, that the virus of cancer is diffused throughout the economy, but localizes itself at certain points of irritation, or in certain tissues predestined to afford it a favorable soil.

The report on cultivation-experiments with malignant new growths by Messrs. Ballance and Shattock to the Scientific Grants Committee of the British Medical Association is of special interest, as giving the impression left upon the minds of observers who have subjected cancer to the most approved scientific tests. They say: "Although we have established the fact by these experiments that no micro-organisms admit of being cultivated from malignant new growths on any of the chief media at present in general use, we hold, nevertheless, that the parasitic theory, in some form or other, is the most probable of any of those yet advanced." It should be remembered that in those diseases in which the micro-parasite has been discovered, the new formations are inflammatory in nature. They belong to the class of affections designated by Virchow as granulomata. On the other hand, in cancer the epithelial cell is evidently the seat of the microbe, if such exist. We have here an entirely different soil, and it seems probable that essentially different methods of culture will have to be devised to develop the organism.

Possibly the secret of the failure of Messrs. Ballance and Shattock may be found in the recent telegraphic reports from Berlin, in which it is stated that Dr. Scheurlen has succeeded in isolating a bacillus which he had "cultivated according to the usual methods." His investigations were however said to be much impeded by the long period of incubation, many months being necessary to cultivate the parasite. The English observers did, indeed, find micrococci and bacilli, but such growths were also found in the cultures of normal tissues. The general verdict of the physicians of Berlin upon Dr. Scheurlen's observations appears to have been unfavorable. A report, however, states that "in twenty cases of bacillus found between cancer-cells, specimens were cultivated in the serum taken from human cases of pleurisy, and were injected into six dogs. The injection yielded, in two cases, tumors which proved to contain the same bacillus."

An announcement of this nature coming from Berlin at the present time, when the public are greatly interested in the question of cure of cancer, is, of course, to be received with great reserve.

It seems, at least, highly probable that the solution of this question is to be sought for by some new method of culture or inoculation differing materially from those introduced by Koch and Pasteur, and now in general use.

Even supposing a specific microbe to have been discovered for cancer, the problem of a cure, or even of prevention, may be still as difficult as in the case of tuberculosis. The hope of Sir James Paget that we may find a medicine as efficient against cancer as mercury and quinine are against syphilis and malaria, implies a belief in a more close relationship of these diseases than we are, perhaps, prepared to admit. The frequently expressed opinion of so high an authority, and the lesson which many recent discoveries teach, leads us to feel that there is ground for hope in the future, and that some clew may, at least, be found by which knowledge may be gained to enable us to mitigate the terrors of so formidable a disease.

WORD-BLINDNESS.

IN his "Treatise on Practical Medicine" published in 1838, Gendrin speaks of patients "who find it impossible to read, but who can write by a sort of memory of the movements of the fingers necessary to trace the words; when once the letter is written, the patient is no longer able to recognize it." An almost identical description is given by Trousseau, in a clinical lecture, of a form of aphasia first described and named as a distinct species by Kussmaul in 1877, and called by him *word-blindness* (Wortblindheit).

Charcot, in his last volume on "Diseases of the Nervous System,"[1] sums up the details of sixteen observations, of which one had been carefully studied by himself; these cases have all appeared in the medical journals the past few years. The following, in substance, are Charcot's conclusions: In general, the onset of this form of aphasia has been sudden, and attended, at first, with a certain degree of right hemiplegia, which has soon disappeared. During the first few days there is almost always a little motor aphasia, which vanishes later, the word-blindness alone remaining. There are, however, exceptions to this, and, in a remarkable case, originally reported by Gueneau de Mussy in Galezowski's *Journal Ophthalmologique*, the word-blindness made its appearance isolated from all other complications of a paralytic kind. It is true, however, that a right-sided hemiplegia soon followed.[2]

Visual troubles have been somewhat vaguely mentioned in connection with a certain number of cases. The patient whose case was reported by Westphal (*Zeitschrift für Ethnologie*, 1874), and the patient who was the subject of Charcot's description,[3] had well-marked hemianopsia. So, also, with Gueneau de Mussy's patient.

A peculiarity of typical cases is that when the subjects of word-blindness make efforts to read a book or manuscript, they are obliged to trace out the letters and words with their fingers before they can obtain any understanding of what they are endeavoring to read. The ideas imparted by these movements of the fingers appear to be indispensable to give value and precision to the vague motions furnished by the visual images; in other words, the patient can only read by writing. In Charcot's patient, these digital movements, which were so necessary to supplement the sight in obtaining the recognition of words, were instinctive; in no other way, in fact, could the visual memories be recovered.

Charcot gives the results of three autopsies: one pertaining to a patient of M. Déjerine, another to a patient of M. Chauffard, the third to a patient of MM. Heilly and Chantémesse. These three observations perfectly agree in one point: the predominant lesion was found to be in the inferior parietal lobule, with or without participation of the angular gyrus and the first temporal convolution. In cases in which there was lesion of the latter convolution, the verbal blindness was found complicated with word-deafness. Charcot finds reason to conclude that the lesion on which verbal blindness depends has for its seat the inferior parietal lobule, with or without participation of the angular gyrus. The existence of the lesion in those parts of the cortex which cerebral physiologists have, with very general unanimity, fixed upon as the visual perceptive centre, easily explains the hemianopsia which characterized several of the cases. As for the precise alteration by which verbal blindness is determined, we are still dependent on conjecture, although there is reason to believe that the primary vascular lesion is generally a plugging (thrombosis or embolism) of the Sylvian artery, which furnishes branches to Broca's convolution, the seat of motor aphasia, and to the regions where verbal blindness and hemianopsia seem to have their location. The lesion of these arterial branches is the primary fact, and the atrophy or softening of the cerebral tissue the consequence.

Gueneau de Mussy, who had an opportunity of studying a remarkable case, which is treated in his usual thorough and philosophical manner in the last volume which he published, proposed to substitute for the name *word-blindness* (*cécité verbale*), and the appellation *aphasic amblyopia*, which Galezowski had bestowed on this affection, the term *asémiognosie optique* (optical asemiognosia); that is, absence of the knowledge of signs. This term seemed to De Mussy more exact than that of *word-blindness*, for there is really no *blindness* present in the ordinary acceptation of the word, and the patient has lost the comprehension not only of words, but of letters. "In adding to the word *asemiognosia* the adjectives of visual or optic, acoustic or tactile, we may," says this writer, "express the different varieties of this intellectual trouble, or their combination." The term is a good one, though too cumbersome, and is not likely to supplant that originally proposed by Kussmaul.

To conclude, all studies thus far made in this department of cerebral physiology testify in favor of the division of the memory into several forms, which correspond to the impressions furnished by the different senses; "and it seems very probable that each of these forms is in relation with a distinct department of the cerebral substance which is the material condition of the formation of these sensorial memories, of their conservation, and of their transmission without."

MEDICAL NOTES.

— The daily papers report that a passenger by the *Alesia*, after being dismissed from quarantine in New York, went to his destination in New Bedford, Pa., where his wife washed and "disinfected" his clothing. She soon sickened and died, of a peculiar disease not diagnosticated. The undertaker who buried her was taken sick soon after. The husband, himself, died in course of a day or two, and his son and daughter, to-

gether with some other inhabitants of the place, are now sick in a singular way. The nature of the symptoms is not reported, and the physicians are said to be in doubt as to the character of the affection.

— Prof. Celli has been made Professor Extraordinary of Experimental Hygiene at Rome.

— The *Medical Record* says that the total annual expenses of the twenty-eight hospitals in New York city are $740,722. The total income from invested funds is $142,142; from pay patients, $163,808.69; from the city, $56,355. This leaves a deficit of about $300,000, to be made up by private subscriptions and by the hospital collections. There are annually treated 13,926 patients, of whom only 25 per cent. pay. In out-patient departments there were treated 119,124 patients. These figures do not include the city hospitals, Bellevue and Charity, or the large independent dispensaries. The addition of these easily doubles the number of medical paupers of the city, bringing the total up to over a quarter of a million.

BOSTON.

— A case came up in the superior criminal court, December 6th, before Judge Bacon, on the interpretation of the Sunday law passed at the last session of the Legislature, as to the meaning of the word "drug," and what it includes. An apothecary was tried for a violation of the law. It appeared in the evidence that the violation consisted in selling a cigar. Counsel for the defendant claimed that a cigar was a drug, and came within the section of the law relating to drugs and medicines. In support of his view of the case, he cited various authorities, and quoted freely from Worcester and Webster as to the definition of tobacco. In his instructions to the jury, the judge said if they found that tobacco was a drug or medicine, then they must acquit; but if they found that it was not a drug, then the defendant would be guilty. The jury, after being out a short time, returned a verdict of not guilty.

— The Boston Medical Library Association has authorized its Executive Committee to purchase land on St. Botolph St., on which at some time in the future to erect a library building. In order to secure the new lot it has been necessary to place a mortgage upon the newly purchased land, and also upon the present library building.

— A slight exacerbation in the number of cases of scarlet fever took place last week, coincidently with the warm weather of the last days of November. The serious prevalence of the disease noted a few weeks before was not, however, by any means reproduced. The cases reported for the week were 72, with 15 deaths, as against 64, with 17 deaths, the previous week.

NEW YORK.

— The beautiful building of the New York Cancer Hospital, on Eighth Avenue, between 105th and 106th Streets, was formally opened on December 6th, when addresses were made by John E. Parsons, Esq., President of the Board of Trustees, the Rev. John Hall, D.D., Drs. Fordyce Barber, and William H. Draper; and the music was furnished by the choir of St. Thomas Church.

— Dr. Charles H. Bradley, formerly of Chicago, where he was for a time under treatment in an insane asylum, who is a victim of the cocaine habit, has been arrested for petty thefts from physicians, and committed to the charge of the Commissioners of Charities and Correction.

—The hospital-ship *Washington*, which has been stationed in Gravesend Bay, has been brought up to the city, and it is said that the New York Quarantine is now entirely free from all contagious diseases.

— A man died of hydrophobia at the Brooklyn Hospital on November 29th, having been bitten by a rabid dog in September last. In this case the convulsions were controlled to a considerable extent by curare, given by hydrophic injection.

— Dr. William T. Lusk has recently performed another successful Cæsarian section, by the modified Sänger method, at Bellevue Hospital, the second since the beginning of the autumn. The infant unfortunately died of tetanus, but at last accounts the mother was doing admirably.

Miscellany.

POISONING FROM ANTIFEBRIN.

A CORRESPONDENT of the *Therapeutic Gazette*, Dr. F. M. Bauer, reports that he has several times witnessed cyanosis produced in female patients by 3 or 4½ grain doses of antifebrin. He has not seen it act so in men. The same journal quotes from the *Deutsche Medicinal Zeitung*, a case reported by Dr. Goll as the only one to his knowledge before the profession of antifebrin poisoning. Unfortunately in the latter case the amount of the drug used is not clearly indicated.

"Mrs. D., who suffered from nervous headache, advised by an article in the *Berliner Lokalanzeiger* purchased twenty-five pfennigs' (about six cents) worth of antifebrin, and put the entire quantity in two portions, which she drank in close succession.

"In about three hours vomiting began, and a cold sweat broke out all over the body, and the patient sank into a deep faint.

"Several hours subsequently I was called in, and found the face, ears, chest, hands, and feet as cold as ice, and covered with a cold sweat; the abdomen was warm but moist; the face deathly pale; eyelids closed, but when spoken to she would open her eyes; pupils moderately dilated, and showing but little sensitiveness to the light; heart beating violently; respiration rapid; pain in abdomen; nausea with occasional retching, but no vomiting.

"The nervous system was in a most strange condition, for, although the woman lay perfectly unconscious of her surroundings, yet she was able to answer to all my questions promptly and sensibly, although in a weak voice.

"She said she felt as though she were continually falling and that she felt perfectly numb.

"In the morning, after the continued use of strong excitants during the night, consciousness returned, accompanied by a most profuse perspiration. At nine o'clock the temperature was normal; the pulse was still up to 108. The whole abdomen was painful and sore. Strange to say, the patient remembered nothing of her condition the night before, and did not even recall the presence of the doctor. This seems to show that antifebrin produces an effect on the nerves similar to an hypnotic state, in which the patient can be made to answer questions and obey commands without having any self-consciousness.

"The next day the patient showed a marked loss of appetite; the face was flushed, and she complained of a severe headache. The symptoms of the poisoning had disappeared."

SIR ANDREW CLARK ON THE CAUSES OF CHLOROSIS.

SIR ANDREW CLARK recently read a paper before the Medical Society of London, published in the *Lancet* of November 19th, in which he contends that the anæmia or chlorosis of girls, arising in nervous constitutions with imperfectly developed sexual organs, is caused for the most part, and in the first instance, by feculent retention and its consequences, and that the right as well as speedily successful treatment lies in the enforcement of a sound hygiene, the administration of ferruginous cathartics, and in the provision after cure for a daily and, as far as possible, a natural relief to the bowels.

Fæcal anæmia, is the name he gives to this condition, and he claims that disorders of the generative system have received much more attention than they are entitled to as causes of the disease. He says: "In the period between the advent of menstruation and the consummation of womanhood there arise physical, mental and moral changes which greatly influence the girl's habits of life and thought. She becomes self-conscious, and enters into new relations with those whom she meets. She thinks of her appearance and tightens her waist. Afraid of getting fat, she stints herself in food, and eats of only dainty things. With her sense of modesty deepened, she is shy of being seen about the closet. Unprompted by nature, and perhaps disdainful of such affairs, she omits the daily solicitations of the bowels. And so at last it happens, through the compressed waist, the insufficient food, and the disregarded desire or the neglected trouble, that the bowels become either obstructed, confined or inadequately relieved. In either case the fæces accumulate, are retained, and not only undergo changes in themselves, but provoke changes in the mucous membrane with which they are in contact. As one of the results of those changes, both chemical and biological, there are produced new substances, ptomaines and leucomaines, which are injurious to the organism, and which, absorbed into the blood, originate in girls of a nervous type of organization those alterations of the constitution of the blood which constitute the true pathogeny of this anæmia of girls.

"Now, it is necessary to ask if this alleged cause of the malady is adequate to the explanation of it? Well, it has been shown by Bouchard, in his lectures on Self-intoxication in Disease, that the poisonous activity of human fæces, even in healthy men is very great. And he concludes that there are formed throughout the intestines of an adult in twenty-four hours a quantity of alkaloids, which, if excretion were stopped and all were absorbed, would be sufficient to destroy life. It is, then, impossible to doubt that poisonous alkaloids are formed in the alimentary canal; that when excretion is seriously diminished they must be in some degree absorbed; and that, mixing with the blood and entering the tissues, they must produce some sort of injurious effects determined by the rate of absorption and the amount absorbed."

ACTINOMYCOSIS IN A WOMAN.

THE *British Medical Journal*, for November 19th, contains the report of a case of this affliction originally published by Dr. Hoeffner in the *Gazette Medicale de Strasbourg*. The patient was a woman, aged sixty, who suffered in November, 1884, and January, 1885, with pains in the right loins resembling renal-colic. Each attack was followed by urticaria and diabetes insipidus. In April, 1885, the attacks grew longer and more frequent; much muco-pus was passed with the urine, and there was great pain and tenderness in the region of the right kidney. In November, the attacks recurred, but this time resembled gall-stone colic; the pain radiated from the liver to the right shoulder. In January, 1886, a swelling resembling an abscess, formed in the right hypochondrium, and was opened by Professor Boeckel in February. Instead of pus, serum with fungous tissue came away; it was sprinkled with grass-green bodies, the size of a grain of wheat. No communication could be found between the incised structure and the abdominal cavity. The wound was scraped, disinfected, and dressed with iodoform gauze. The green bodies were examined and found to be actinomycetes. The wound slowly became cleaner; its edges remained red and indurated, and not very tender. The scanty pus which exuded was mixed with the bright green bodies. There were indurated tracts in the neighborhood; no antiseptics produced any effect. At this stage the general condition was good; the urine contained muco-pus, but the fungus could not be found in it. The wound at length became a fistulous track. In June, 1886, pleuritic effusion set in in the right side of the thorax inferiorly, with rise of temperature, On June 27th, fits of coughing brought up fœtid muco-pus. In August, the patient became very ill with ascites, anasarca, jaundice, and a bedsore, yet she got stronger again till spring, 1887, An abscess then formed in the inner side of the right scapula. On incision, thick pus and actinomycetes escaped in quantities; a fistulous track was left which, alternately with the track in the right hypochondrium, discharged the parasite. The former track on one occasion communicated with the pulmonary fistula, then the green bodies were found in the sputa; they were not so green as those escaping from the other cavities. The patient died of exhaustion on July 30, 1887. The disease thus lasted for two years and a half. A large abscess was found in the right lobe of the liver, involving adjacent viscera. It was full of the fungus; it communicated with the lumbar fistula, which was itself in communication, under a wide area of upheaved subcutaneous and

muscular tissue, with the fistula in the thorax. The right suprarenal capsule adherent to the liver was infected with the fungus, but the kidney, including its capsule, was free from infection, though congested. The diaghragm and other organs were healthy. The fungus appeared to have begun its ravages from the right transverse colon, where it touches the liver. The fungus had migrated towards the surface, through the thoracic parietes, forming the first abscess; then it had made its way between the skin and the muscles towards the scapula, perforated an intercostal space, and finally entered the lung. The green coloration of the fungus appears to be peculiar to cases where the abscess is hepatic; in other cases the masses were white or yellow, and even in this patient those which were coughed up from the lung were much less green than those in the hepatic abscess.

THE PUERPERAL INVOLUTION OF THE UTERUS.

THE *American Journal of Obstetrics*, November, 1887, contains a review of an elaborate paper by Th. B. Hausen, (*Ztschrft. für Geb. u. Gyn. XIII*, 1). After an analysis of the results obtained by others from external and internal measurements undertaken during the puerperium, the author describes in detail his own experiments and the method after which they were undertaken. These measurements were one thousand and forty-eight in number, performed on two hundred puerperæ, on the tenth day post partum, on the fifteenth day, then every week up to the end of two months, and every two weeks to the expiration of twelve weeks after labor. The results are tabulated under the respective headings, Primiparæ; Multiparæ; Miscarriages; Premature Labors; Non-nursing Women; Complicated Labors; Complicated Puerperium. The conclusions may be summarized as follows: (1) In twenty-five instances (twelve primiparæ, thirteen multiparæ) after normal labor at term, the progress of involution was noted beyond eight weeks, and in one-half involution was then complete, whilst in the remainder this did not occur till the third month. No special difference was found to obtain as regards the progress of involution in primiparæ and in multiparæ after the tenth day. Involution seemed to progress less rapidly after premature labor than after labor at term. In the normal puerperium, after normal labor at term, the uterine cavity remained larger and the process of involution was more protracted in women who did not nurse than in those who did. In the normal puerperium after twin births, or after those complicated by much hæmorrhage, involution was somewhat slower than after uncomplicated labor; the difference was especially marked on the tenth and fifteenth day. Retention of the secundines seems to be a cause of protracted involution.

Hausen also made a number of measurements for the purpose of determining whether any deductions of value from a medico-legal standpoint could be drawn. In one hundred and sixty-three puerparæ, fifteen days after delivery near term, in two only was the measurement less than nine centimetres; three weeks after delivery, of one hundred and thirty-five cases, in two only was the measurement less than eight centimetres. The conclusion is thence drawn that, if on careful measurement the uterine cavity measures much below eight centimetres, the chances are very slight that a child has been born within three weeks; and if the measurement is not at least nine centimetres, then the chances are exceptionally slight that delivery has occurred within two weeks. Generally then, measurement by the sound two weeks after delivery at term, or within six weeks of term, will give us positive indication as to delivery having occurred; after the third week, the data obtainable are lacking in value as positive evidence.

The last question considered, is the form and position of the uterus during involution. The results of examinations were: On the tenth day, he found anteflexion, 95 per cent.; pure anteversion, one case; retrodeviation, no case; on the fifteenth day, anteflexion, 85 per cent.; normal position, 11 per cent.; retrodeviation, 3.4 per cent.; six weeks after delivery, anteflexion, 75.6 per cent.; retrodeviation, 5.5 per cent.; normal position, 50.9 per cent.

Correspondence.

THE "DOCTOR'S WIFE." A BACHELOR'S WAIL.

MR. EDITOR,—Your remarks in the last issue of your valuable JOURNAL upon the Doctor's Wife, call forth from my heart certain personal reminisences not unmixed with pain. "Pins," says the infant prodigy "save a great many people's lives because they don't swallow them." So, doctor's wives ruin the prospects of hundreds of us young fellows, because we don't have them. Shall I tell you my sad fate?

Two years ago on the death of old Doctor Gamboge, two of us, as is the custom, moved into town to take his place. My friend and classmate, Dr. Benedick (alas, no longer my friend!) and I, each arrived on the ground about half an hour after the old doctor had breathed his last. We were pretty well-matched in what is properly but erroneously supposed to be the preparation for practice, and we entered the race neck and neck. We were, as Virgil says, or might have said, *Et secare pares, et exercere parati.*

Well, we took lodgings on opposite sides of the main street, and the fight began. As fast as I scored a point Benedick scored another, and somehow his points always seemed to count for a little more than mine. I went to the brick church, which was larger, and he went to the wooden meeting-house, which had the most old families. My chimney blew down and I got it in for a five-liner in the local paper, but the next week one corner of his house took fire and he got it in for ten lines. I put on my door an old-fashioned knocker and he put in an electric bell. The country people knew all about knockers, but the electric bell was something they couldn't quite grasp (figuratively I mean; they grasped it often enough literally).

Finally I fell into the common pit, and bought a horse long before I needed it or could afford it. The first time I passed Benedick on the street, he smiled in an unpleasant way and said, "Oho, I've got onto a racket worth two of that," and the next thing I knew he was married.

His wife distanced my horse in no time. She went to the sewing-circle and every good patient he ever had was brought into the conversation in some way. Even if he was only called into a house to see the cook, the women all learned that he had been there, though they didn't know (for I "mustn't talk about my husband's affairs,") who the patient was.

Then, when the wedding-calls were returned, into every house went some mysterious hint, not too definite, of Benedick's wonderful success. Were there children in the family: "The Doctor is so fond of children, and they all

take to him so quickly!" Had any of the household met with an accident: "The Doctor is very fond of surgery." Were any little dresses in making: "My husband is such a good baby-doctor. Whatever should I do if it weren't for him!"

She always found out who the family physician was, and this information, of course, was the first and most important step towards ousting him. If a new-comer moved into town, the grocer and butcher were hardly more prompt in leaving their cards at the back door, than Madame in presenting *her* business-card at the front door. If little Susy Simmons swallowed a pin, and the horrified mother was running amuck for the nearest doctor she could find, she was beguiled in by Mrs. Benedick to wait for her doctor, whom she "expected in every minute." No emergency cases ever would wait for me to come home, and whenever a patient eager for immediate healing turned away from my door, he was invariably gathered in by the siren across the way, who either entertained him till her partner's return, or else got his name booked for a visit.

They were two, or more than two, to my one. It takes two men to run the Punch and Judy show — one to work the figures, the other to do the talking, get in the crowd, and take up the collection. I had to run my show alone, and didn't take up much money.

I wonder if King Lemuel's mother did not have such a doctor's wife in mind when she told him the memorable story of the virtuous woman. There are certain internal evidences that she did. "She perceiveth that her merchandise is good. *Her candle goeth not out by night.* . . . Her husband is known in the gates, where he sitteth among the elders of the land." By the way, Mrs. Benedick has already got her husband onto the School-Committee, and, I hear, is thinking of sending him to the Legislature next year.

There is nothing left for me but to move on, and try it somewhere else. *Væ victis.* I fondly thought when I spent my money for a horse and carriage that I held the "right bower"; but I have found that Benedick has the "joker." And now, before trying my fortune in a new field, I must have, cost what it may, a wife. Bitter experience, as well as the tenor of your editorial, convince me of it.

I am, sir, yours in search of a wife, CŒLEBS, M.D.

SKIN GRAFTING AND SEVERED DIGITS.

NAVY YARD, CHARLESTOWN, November 29, 1887.

MR. EDITOR,— I beg leave to submit the following (from Corneil and Ranvier's "Histologie Pathologique") concerning skin-grafting. "The presence of epidermic cells, transplanted to the middle of a granulating sore of the skin, determines an active reproduction of epithelium all about the graft. The epidermic cells seem to act not by multiplying themselves but by a kind of *action de présence* which leads, as it were, the evolution of the surrounding embryonic cells in a definite direction; for the graft itself gives no evidence of activity, and is soon destroyed in midst of the new epithelial tissue the appearance of which it has determined."

This may be of interest, also, to those who believe that bits of fingers, phalanges, etc., after complete removal, wholly severed from nervo-vascular connection, may continue or resume vital action. Very respectfully,

F. B. STEPHENSON, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 26, 1887.

Deaths reported 1,889: under five years of age 640; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 341, acute lung diseases 290, consumption 268, diphtheria and croup, 165, scarlet fever 47, typhoid fever 47, diarrhœal diseases 30, malarial fever 14, measles nine, cerebro-spinal meningitis nine, whooping-cough seven, erysipelas seven, puerperal fever six. From diarrhœal diseases, New York eight, Boston five, New Orleans four, Baltimore three, Brooklyn, Pittsburgh, Lowell, and Haverhill two each, Milwaukee and Fall River one each. From malarial fever, Brooklyn six, New York and New Orleans three each, Baltimore two. From measles, New York six, Baltimore three. From cerebro-spinal meningitis, New York four, Baltimore, Milwaukee, Worcester, Lowell, and Fall River one each. From whooping-cough, Milwaukee three, Brooklyn two, New York and Boston one each. From erysipelas, New York three, Brooklyn, Baltimore, District of Columbia, and Nashville one each. From puerperal fever, Portland, New Orleans, Pittsburg, District of Columbia, Lynn, and Chelsea one each. Cases reported in Milwaukee, scarlet fever 31, diphtheria nine.

In 23 cities and towns of Massachusetts with an estimated population of 1,078,330, the total death-rate for the week was 21.41 against 21.90 and 20.85 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending November 12th, the death-rate was 20.0. Deaths reported 3,548: infants under one year of age 768; acute diseases of the respiratory organs (London) 438, scarlet fever 111, measles 82, whooping-cough 58, fever 53, diphtheria 43, diarrhœa 37, small-pox (Sheffield 17, London 1) 18.

The death-rates ranged from 9.3 in Brighton to Oldham 29.6; Birmingham 21.8; Bradford 21.6; Hull 14.8; Leeds 19.4; Leicester 18.2; Liverpool 21.0; London 19.4; Manchester 28.3; Newcastle-on-Tyne 22.9; Nottingham 15.4; Sheffield 21.4; Sunderland 14.5.

In Edinburgh 16.5; Glasgow 22.2; Dublin 32.1.

The meteorological record for the week ending November 26, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Nov. 26, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 26, 1887, TO DECEMBER 2, 1887.

So much of S. O. 235, A. G. O., October 8, 1887, as relieves LT. COL. CHAS. T. ALEXANDER, surgeon, from duty at St. Louis, Mo., and directs him to report for duty at Fort Meade, Dak., is amended so as take effect January 1, 1888. S. O. 274 A. G. O., November 25, 1887.

BIRMINGHAM, H. P., captain and assistant surgeon. Leave of absence granted by order No. 52, Fort Myer, Va, November 24, is extended twenty-three days. S. O. 255, Division Atlantic, November 28, 1887.

SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. — The Section for Clinical Medicine, Pathology, and Hygiene will meet at 19 Boylston Place, on Wednesday, December 14, at 7.45 o'clock. Business: Final Report of the Committee on Metropolitan Milk-Supply. Dr. J. W. Farlow will read a paper on "Hypertrophy at the Base of the Tongue, with Report of Cases." Dr. F. I. Knight will open the discussion. Dr. W. D. Hodges will read a paper on "An Epidemic of Measles." Dr. S. H. Durgin will open the discussion. Dr. J. B. Jerould, of North Attleboro, will exhibit a patient presenting the unusual phenomenon of Objective Tinnitus Aurium.

A. L. MASON, M.D., *Chairman.*
ALBERT N. BLODGETT, M.D., *Secretary.*

GYNÆCOLOGICAL SOCIETY OF BOSTON. — A regular meeting of the Society will be held at No. 19 Boylston Place, on Thursday, December 15th, at 4 o'clock P. M. Papers: Dr. Helen L. Betts, "Woman's Dress — its Relation to the Etiology and Treatment of Pelvic Disease." Dr. C. W. Stevens, "A Case of Puerperal Septicæmia."

H. J. HARRIMAN, M.D., *Secretary.*

APPOINTMENT.

CHARLES W. TOWNSEND, M.D., has been appointed Assistant in Obstetrics in the Harvard Medical School.

TYPHOID FEVER IN CINCINNATI.

Typhoid fever is, at present, epidemic in Cincinnati. The visitation is chiefly attributable to the state of the Ohio River, which, we learn from the *Medical News*, has never been so low since 1881, when this disease was unusually prevalent. The death-reports for the week average about six per day; the number of cases is variously estimated at six hundred to one thousand. The various hospitals of the city contain about one hundred and fifty cases. The disease prevails in all parts of the city, in the most remote suburbs, as well as the city proper. Upon the advice of physicians, most families take the precaution of boiling all the drinking-water and milk. It is a common sight to see children on their way to school with bottles of boiled water slung across their backs with their satchels. There is general testimony at the medical societies that the disease is mild, though the mortality report is much larger than at any time in the history of the city. One prominent physician says that he has seen, in private practice, more cases of severe hæmorrhage than in any previous experience with the disease.

Drs. Rushford and Cameron, of the Bacteriological Laboratory of the Medical College of Ohio, have succeeded, by Brouardel's method, in discovering by culture-experiments, and demonstrating before the Cincinnati Academy of Medicine, the bacillus of typhoid fever in the waters of the Ohio River.

BOOKS AND PAMPHLETS RECEIVED.

The True Nature and Definition of Insanity. By C. H. Hughes, M.D., former Surgeon, United States Army, late Superintendent and Physician-in-Chief, Missouri State Lunatic Asylum, etc. St. Louis, Mo. Reprint. 1887.

The Present State of our Knowledge regarding Localization in the Cortex Cerebri. By Landon Carter Gray, M.D., Professor of Nervous and Mental Diseases in the New York Polyclinic. Reprint. 1887.

Syphilis of the Nervous System and its Treatment. By Landon Carter Gray, M.D., Professor of Nervous and Mental Diseases in the New York Polyclinic. Reprint. 1887.

HINTS TO PHYSICIANS SENDING THEIR CONSUMPTIVE PATIENTS TO COLORADO.[1]

BY EDWARD O. OTIS, M.D.

Of the advantages of the Colorado climate for either the arrest or cure of many cases of phthisis I do not propose here to speak. That matter, I shall assume, has been already settled by the physicians to whom I address this paper. I will, however, say in passing, for the benefit of those who may desire to investigate the subject, that it has been very carefully considered, with abundant and reliable data, as to temperature, humidity, cloudiness, winds, etc., by Dennison, Fisk, Solly, Eskridge, Wagner, and many others. Especially to be recommended are the papers of Dr. Fisk, of Denver, in various periodicals, giving careful and honest deductions from climatic tables and observations of indisputable authority. I will only stop to add to the large mass of meteorological evidence already adduced in favor of the climate the results of some private observations, made, and recently communicated to me by Dr. Hazelhurst, of Colorado Springs. These observations are for the last three winters, and I have arranged them in tabular form, so that one can see at a glance the number of clear, fair, cloudy, and stormy days. For comparison's sake I have also a table of the weather here in Boston during that time, kindly furnished me by the signal officer at this station. I add also a third table, giving a synopsis of the two previous ones.

TABLE I. BOSTON.

Synopsis of Weather Observations for the winter months. December, January, February, March, for the three years, 1884–85; 1885–86; 1886–87; made at the United States Signal Station at Boston.

	1884-5	1885-6	1886-7		1884-5	1885-6	1886-7
	Dec.	Dec.	Dec.		Feb.	Feb.	Feb.
Clear	6	8	6	Clear	12	10	6
Fair	12	11	12	Fair	10	10	11

Stormy	*9	*18	*12	Stormy	*9	*17	*11

*Including days on which .01 inch of rain or snow fell only.

As a further bit of experimental evidence I will say that in a conversation with one of the physicians of Colorado Springs last summer he told me that he had that very season, after a residence and practice of fifteen years in Colorado, met with the first case of phthisis that seemed to have originated in that climate.

It is unfortunate that up to the present time more physicians treating large numbers of phthisical cases in Colorado have not published the results of their experience; but outside of the two hundred and sixty cases by Dennison, I know of none. It is likely, however, that there will soon be given to the public the results of a large number of cases, carefully noted and observed during many years of practice at Colorado Springs.

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene, of the Suffolk District Society, November 9, 1887.

TABLE II. COLORADO SPRINGS.

Synopsis of Weather Observations for the four winter months, December, January, February, March, 1884 to 1887 inclusive; made by Dr. Hazelhurst, of Colorado Springs.

TABLE III. BOSTON AND COLORADO SPRINGS.

Synopsis for Weather Observations for December, January, February, and March, from 1884 to 1887 inclusive (three years), with the exception of December, 1886, and March 1887, at Colorado Springs.

	Boston.				Colorado Springs.			
	1884-5	1885-6	1886-7	Total	1884-5	1885-6	1886-7	Total
Clear	35	34	27	96	57	88	26	171
Fair	50	47	44	141	41	13	29	83
Cloudy or overcast	36	30	50	116	8	8	4	20
Stormy	41	59	49	149	4	8	2	12

For the two years, 1884–85, 1885–86, during December, January, February, March, there were:
In Boston, 69 clear, 66 cloudy, and 100 stormy days.
In Colorado Springs, 149 clear, 16 cloudy or overcast, and 8 stormy days.

For the three years, 1884 to 1887, inclusive, during January and February, there were:
In Boston, 53 clear, 59 cloudy, and 73 stormy days,
In Colorado Springs, 106 clear, 3 cloudy, and 7 stormy days.

From a somewhat careful consideration given to the numerous health resorts throughout the world, and a personal acquaintance with some of them, I am prepared to say that I know of none possessing so nearly a perfect climate for many cases of phthisis, taking it all in all, as that of Colorado; or so nearly fulfilling the conditions necessary for the most successful climatic treatment. "Climatic treatment," says Lindsay,[2] "aims at removing the patient from a climate which induces an indoor and sedentary life to one where an outdoor life of healthful activity may be continuously enjoyed, without hindrance from meteorological conditions. Climatic treatment aims at removing the patient from a comparatively sunless and depressing climate, which impairs vitality and lowers nutrition, to a sunny and tonic climate where appetite, digestion, and sanguification undergo such augmentation as may enable the patient to shake off or hold at bay the tendency to consumptive disease." All this, I believe, does the Colorado climate, and with this opinion, I am confident that very many physicians who have considered the subject, or who have had personal experience in the climate under consideration, will agree. Health resorts there may be which excel in this or that regard, but none, I believe, which possess such an all around favorable climate for phthisis as that of Colorado. One may urge as an objection to it

[2] The Climatic Treatment of Consumption, a Contribution to Medical Climatology. By James Alexander Lindsay. Macmillan & Co., 1887.

that it is like a mouse-trap, when you are once in it you are obliged to stay there; but is not this true to a great extent of any health resort worthy of the name? Fortunate is the consumptive who can live comfortably and indefinitely, with a chance of getting well, anywhere, particularly among the beauties and attractions of Colorado.

My object, in the present paper, is to aid the physician of the same opinion as myself regarding the Colorado climate, to give his patient, whom he is sending hither, such hints and advice as will enable him to settle and live in the new climate with greater ease, comfort, and safety, than he might otherwise do if left to pick up the knowledge requisite for this by his own experience.

Having spent the last summer in Colorado, I was there long enough, perhaps, to appreciate the many bits of knowledge necessary and useful for the newcomer, and not too long to forget or overlook them. When the physician says "go to Colorado," he may not realize that the State is nearly as large as New England and the State of New York together, or larger than England, Scotland, and Wales; and he must, therefore, give his patient more specific directions than these. How often, alas, is one sent to a new climate in just this vague way, or even left to make the selection of a proper climate for himself![3] Generally, however, the physician means Colorado Springs, for there the larger number of invalids or "lungers," as they facetiously call themselves there, go; and undoubtedly this town is better prepared to care for the consumptives than most others in Colorado, for it is not an inconsiderable source of revenue to the inhabitants. Scattering cases go to Cañon City, Denver, Salida, Boulder, and other places, but, with the exception of Denver, the accommodations are probably far better in Colorado Springs, if one is able to pay for them. Some, mostly young men, go out on a ranch, if they are strong enough to endure the hardships and privations consequent upon such a life; but they must be prepared for poor food, and much of it canned. Wherever the patient goes, the physician under whose care he comes — and he should be under the observation of some medical man — should be informed by the home physician, of the history and condition of the patient. Better is it if the new physician is personally known by the one at home. Moreover, the former will render great assistance to the recently-arrived invalid by advising him as to boarding places of good repute, and in wholesome localities, and, indeed, in a thousand other ways.

The majority, then, of consumptives, as I have said, go to Colorado Springs, a town of seven thousand, or more, inhabitants, with the purest of drinking water from the melting snows of Pike's Peak. Its streets are traversed by irrigating ditches, from which the lawns and yards are frequently flooded in summer, which has been considered by some persons productive of too much dampness. On one side of the town are the foot-hills and mountains, and on the other the limitless plains, thus offering an endless variety of rides and drives. Almost all the conveniences, and luxuries even, that one has been used to at home, can be obtained here. There are good shops of all kinds, and the markets are well supplied. Fruit comes from California, beef from Kansas City, and game from Colorado itself. There is an opera-house for passing shows, a club-house, a free postal-delivery, and a horse-railroad. The town is most orderly, and there is not, or cannot be, from the conditions under which all building lots are sold, a drinking saloon in it. The physicians, nearly all of whom are there per force, on account of pulmonary trouble, are men of ability and skill. There is no system of sewerage as yet, but one is in contemplation, and, I should say, was much needed. The boarding houses are many, and, for the most part, seem to offer good accommodations, the average price of board and lodging being from twelve to fifteen dollars a week. What the physicians there advise, and which obviously is the best plan, is housekeeping, if the invalid is strong enough, and is with friends; but rents are high. There is a good hotel, the "Antlers," where the new comer will spend his first few days until he has selected his permanent quarters. The character of the society is much like that of a summer resort, quite cosmopolitan, as one would naturally expect from the coming together of people from so many different parts of the country.

There are many — too many — social entertainments, teas, balls and the like, where consumptives are crowded together in a small space, and strength which ought to be husbanded is wasted in this way. The physicians see and fight against these excesses, but there, as elsewhere, it is hard to stem the tide of fashion and society. The daily life of the invalid is essentially an outdoor one, which is very possible when one considers that there are only about thirty-five to forty-six cloudy days in the whole year, and from "October 1st to April 1st there is an average of less than one-half a day of each week when the patient will be deprived of sunshine."[4] During the winter there is practically no rain, and one can sit on the veranda or be in the saddle every day; the day of sunshine during this season being about eight hours.

For some time after coming to this altitude (Colorado Springs being 6080 feet high), comparative rest and inactivity is enjoined, and probably with wisdom; but sometimes it seemed to me that this injunction was carried to an extreme, and that moderate exercise would have hastened the improvement, or recovery. Horseback riding is the exercise par excellence at Colorado Springs, as elsewhere in the State, and horses are good, and comparatively cheap. The rides are innumerable. Out on the plains; to the various Cañons; to Manitou; the Garden of the Gods, etc. Could anything be more exhilarating than a gallop out on the limitless plain in a Colorado saddle, on an easy-riding broncho, the prairie dogs barking at the doors of their little mounds, the rabbits hopping through the sage bush, and in the distance a long line of cattle going for water or salt!

It seemed to me that there was no very great opportunity for one to find remunerative employment in Colorado Springs, for it is not commercially active. Probably some of the other and more busy towns would serve better for this purpose. My impression of Colorado in general, however, is that a man of sufficient strength, with energy and adaptability, who desires self-supporting work, will not be long in finding it. As an illustration of this, I know a young clerk, from this city, who went to Colorado Springs for pulmonary trouble, but who was strong enough to be about and around after a little. At the Springs he

[3] Vide Some Observations on Health Resorts, by the author. Reprint from the Boston Medical and Surgical Journal of March 11, 1886.

[4] Wagner, in a recent issue of the N. Y. Medical Record.

found a cattle-man, who took him into his employ and sent him up into Estes Park to look after his cattle. He got the use of a good horse, and was paid a fair monthly salary, together with his board. Possessing Yankee shrewdness he found an opportunity to preëmpt a quarter-section of grazing land at the same time, and now he bids fair to regain his health, and have some dollars in his pocket at the end.

In summer, Colorado Springs, judging from my experience, is likely to have many uncomfortably hot days, and it seems to be well for the invalid to seek the coolness of the mountains somewhere, and, moreover, it makes a pleasant and agreeable change, after a winter spent in civilization, with its consequent and inevitable evils, to have something of the wild and free life of the mountains. There are many of the so-called mountain parks near or more distant, and ranging in altitude from 7,000 to 10,000 feet high, which offer both a cool temperature and all the attractions of grand mountain scenery. One finds hotels in some, in others boarding ranches, and in the more remote places he must go prepared to camp out. In all the food will be found to be more or less bad, depending upon the distance from any source of supplies, but, unless very delicate, the invalid will soon learn to put up with it, and will have such an appetite from the life and invigorating air that he can sit down and eat a piece of raw ham. If one enjoys, and is strong enough for, long trips on horseback, he can start on his horse from Colorado Springs, or Denver, and ride to the mountains, and have his horse there for use. I met a company of young men in Estes Park, two of whom were "lungers," though they looked the picture of health, who had ridden from Colorado Springs, and were en-route for North or Middle Park, with their camping paraphernalia, in search of trout and deer. For those who are delicate, and need moderately comfortable quarters and care, there is Manitou Park, Idaho Springs, Salida, and Poncha Springs, near by. Georgetown, a typical mountain village, most picturesquely situated in a deep, narrow gulch, on Clear Creek cañon, and Estes Park, one of the most charming spots in all Colorado, and of which I shall speak a little more at length. It is one of the smallest of the Colorado parks, and is about ten miles square, and seventy-five hundred feet, about, above sea-level. It is reached, from Denver, by railroad to Lyons or Loveland, and from thence by a stage road of twenty odd miles. The journey is made in a day from Denver. There are but few buildings and settlements in the park, the most of it being owned by the so-called English company. Some years ago the Earl of Dunraven visited the place and was so much impressed with its beauty that he got possession of it. There is a small hotel there of moderate price, and three or four boarding ranches. Ferguson's and James's are the best, at which room and board can be obtained for about twelve dollars a week. Each of these ranches consists of a number of small cabins of two or three rooms, some of logs and others of rough boards, but one is very comfortable in them, and he is, or should be, only in them to sleep. The food is fair for the mountains, about the same quality as in the Adirondacks. It seems paradoxical that the beef should be of poor quality, when all around are herds of cattle preparing for the Chicago market. One has, however, every day, an abundance of the most delicious brook trout.

One of the great charms of the park is the nearness of the mountains. On two sides are the great snowy ranges terminating in Long's Peak, 14,272 feet high, the "Matterhorn of the Rockies." The air is of the purest, and almost every day is a sunny one. Very rarely is it uncomfortably hot, and the nights are always cool. Generally a fire is comfortable. But once during a stay of six weeks there did I notice any dew, and one can sleep under the open sky without danger from dampness. Many spend the summer in tents, which dot the park over, but most of the cabins have chinks and cracks enough in them to let in sufficient air. The flora is large and luxurious, and the botanist will find continual surprises and delights in it. Indeed, I do not see how it is possible to find a clearer or more invigorating air, sunnier or bluer skies, grander or more beautiful scenery in the whole Rocky Mountains than here in Estes Park. I have known of a consumptive getting up from her bed in Colorado Springs to go to the park, and in a short time after her arrival there riding horseback. The winter is not uncomfortable there, I am told, or very cold, and, so far as the climate is concerned, one could well live the entire year there if he could endure the loneliness. Indeed it would be to me infinitely preferable to a winter among the snows and ice of the Adirondacks; and if a mountain health resort of such perfect climate existed anywhere in Europe, Davos would be deserted. If one has passed the winter at Colorado Springs I would advise them to go to Estes Park about the middle of June, when occasional hot days come at the former place, and remain until the first of October. If one rides horseback — and half the pleasure in the park is gone if he does not — it is the cheapest way to take your saddle with you, and buy a pony there, which one can do for forty dollars and upwards. There is a mail once a day, but no telegraph. Comparing my experience of the climate of Estes Park with that of the Adirondacks, I should say that it was rather warmer in the former place, far dryer, and much more sunny. One feels the same invigorating influence in both places. The night temperature is about the same, I should think, in both places.

In winter and spring, either at Colorado Springs or elsewhere in the State, there are occasional high winds—"wind storms" they call them—accompanied with clouds of dust, which may produce an irritating and injurious effect upon those whose pulmonary trouble is accompanied with much secretion, and who have sensitive throats. It may be a question whether it is best for them to remain in consequence of this. The damper, but more quiet and soothing, atmosphere of Southern California, or the South, may serve them better, which is again an illustration of the fact that no one climate suits every case of phthisis.

The best time to go to Colorado is probably in September or October — most delightful months there. The best time to come East for a visit, I should think, would be either in May, June, or October. The best way to go from Boston is, in my opinion, by the New York Central and Lake Shore Railroads to Chicago, and from the latter city to Denver by the Chicago, Burlington and Quincy Railroad. By this route there is but one change from Boston to Denver.

One or two general hints in closing, and then I desire to present a rather remarkable series of photographs of Colorado Springs and surroundings, and of

Estes Park, which I am enabled to do through the kindness of Mr. F. H. Chapin, of Hartford, Conn., who took them.

Clothing.—One should have as thick winter clothing in Colorado as in this climate, for the mornings and nights are often very cold. In the sleeping room, moreover, one must make sure that the floor is tight and covered with a warm carpet. A fire should be made in the morning before the invalid arises.

Expense.—It is expensive both going to and living in Colorado. The cost of the journey there is from seventy-five to one hundred dollars; and board in Colorado Springs, as I have said, is from twelve to fifteen dollars a week. Rent of cottages is from fifty dollars upwards. About the only thing that is cheap is horse-hire.

Effect from the Altitude.—Some patients think it wise to make the ascent from the Missouri River to Denver gradually, so as to become accustomed to the altitude. The majority, however, I think, go at once to the altitude at which they are to live, and generally, so far as I can learn, experience no especial discomfort or harm from doing so. For about ten weeks I lived at an altitude of from six to seven thousand five hundred feet or more, and climbed mountains, three of which were over fourteen thousand feet high, without experiencing the slightest discomfort. Nor, indeed, was I in any way unusually affected, except, perhaps, on three occasions. Twice when on high mountains I had a slight headache, and the third time when at Leadville, which is over ten thousand feet high, nearly to timberline, it seemed to me that in walking I got out of breath more quickly than usual. I have climbed high mountains with one of affected lungs, who seemed to endure the exertion and altitude about as well as I. A curious effect of the altitude was noticed by a physician in his own case. When about ten thousand feet high, at which altitude he generally lived, the fever which accompanied his pulmonary trouble was kept in abeyance. When, however, he descended to a lower level it recurred, or increased in severity.

Length of Residence.—In whatever climate one finds his lung trouble improving steadily, there he should remain, not only until all signs of mischief disappear, but, in many cases at least, as long as he lives. I feel convinced that this is the safest and wisest plan, and I think that physicians of experience are gradually growing to this opinion. This is especially true of the Colorado climate, which is such a radical change from the one the patient is likely to come from. I believe the slow improvement, or lack of any improvement, in many cases is due, partly at least, to the worry over the enforced exile, and eager watching for the time when they think they will be able to return to their homes. It is often noticeable how quickly and permanently those improve and recover who take up their residence in Colorado, and settle down to permanent living there, with their friends and family about them. The contrary is also observed with those who make it a mere health resort, and are separated from their family and friends; as, for instance, a wife from her husband, or a daughter from the rest of her family.

LOCAL MASSAGE FOR LOCAL NEURASTHENIA.[1]

BY DOUGLAS GRAHAM, M.D., OF BOSTON, MASS.

NEURASTHENIA, as I understand it, may be either general or local, affecting the nerves or nerve-cells of all, or any part of the cerebro-spinal or sympathetic system. Its manifestations are those of exhaustion or too easy exhaustibility of nerve-force; and its pathology, malnutrition of the nerve-cells involved, with concomitant instability of their circulation in the form of anæmia or hyperæmia, or alternations of these. It predisposes to, it accompanies, it results from disease; the nervous shock and the tedious recovery from injuries point to other sources, and it may be caused by overwork, worry, or sheer laziness. The agreeable fatigue after a satisfactory day's work that insures sound sleep may be regarded as a healthy form of neurasthenia, if the Hibernianism may be pardoned.

It is a matter of common observation that those who are compelled to hard manual labor seldom suffer from nervous prostration; and amongst the more fortunate who may be predisposed to neurasthenia, those who are deeply interested in some hobby or occupation that keeps mind and body active, have found the best means of prophylaxis. The same means that serves for its prevention also supplies us with a clew to one of the most valuable agents that can be employed for its relief or recovery. Exercise keeps the circulation active, but requires effort of brain, spinal cord and nerves, as well as muscles, at a time when our object may be to afford rest to one or all of these parts of an overtaxed nervous system. Massage supplies this want, and will keep the circulation going with a minimum or no expenditure of nerve-force from the patient, and deep massage without friction will lessen the beats of the heart, and afford it rest also. Nay more, for it is getting to be the fashion not only amongst the laity, but also with some physicians, to say that massage imparts energy to the patient, though I confess I do not exactly understand what this means. Certainly, many who submit to massage feel much more vigorous, light, and supple after even the first application than they did before it. But may not this rather be owing to the rousing of their latent energies, and restoring the equilibrium of their forces, by facilitating the circulation of blood and lymph, and the transmission of nerve-force?

I have previously stated elsewhere that in cerebral exhaustion the relative value of massage was almost *nil*, and that out-of-door exercise was of paramount importance; but I have since found reason to modify this in favor of more massage and less exercise. In such cases, massage of the head alone daily, or every other day, is better than applying it all over the patient, unless there be a rare idiosyncrasy that will not allow the head to be manipulated.

There are people, not a few, who, when using their brains, suffer from uneasy sensations in the lumbar or dorsal region, and these discomforts continue after the cessation of study, causing wakefulness. Generally, there is also some spinal irritation in the region affected. In such cases, massage of the back alone will often induce sound sleep, and, next day, the patient feels inspired with faith, hope, and courage, in place of doubt, dread, and fear of meeting appoint-

[1] Read before the Section of Clinical Medicine, Pathology, and Hygiene of the Massachusetts Medical Society, Suffolk District, November 9, 1887.

ments. With these cases, a much more marked effect is produced by local than by general massage, except when the tenderness of the muscles and spinal irritation is extreme, unfitting them for every kind of work, and then the massage should be general, omitting the back at the first *séances*, but gradually approaching it at subsequent ones.

In other cases of what may be called local neurasthenia, if the term can be allowed for this purpose, such as writer's cramp, or the cold, small, and feeble muscles resulting from injury, disease, or disuse, massage and exercise, carefully adapted, have given excellent results. To these have recently been added another affection; namely, laryngeal cramp of musicians and speakers, for the local treatment of which electricity and massage are considered the most effectual measures.

It is not the purpose of this paper to go into the details of applying massage, nor to consider its minute effects; but I think it will be a revelation to many to experience either in their own heads, or to observe in those of their patients, the light, comfortable, delightful feelings that are produced by the resistance of a skilled manipulator to forward, backward, and lateral movements of the head. The impression is that the interior of the head has been benefited, and the effect is hardly secondary to massage, which rather gives the impression that the exterior has been improved.

The following cases seem to me sufficiently worthy of notice as examples of the conditions mentioned:

Case I. A. J., twenty-three years of age. Three years prior to my being called to him, he had been winning races at college at the same time that the functions of his brain flagged, and study had become so irksome, producing headache and insomnia, that he gave it up for a year. At the end of that time he returned to college for a year, and, to use his own words, "patched up and graduated," and for the year before I saw him he had been trying to recuperate by resting at home. At this time, even walking sometimes produced discomfort in his head. At my first visit he had been suffering from headache, with tolerably acute pains in the external branches of the fifth pair of nerves, and had had but little sleep for four nights. The immediate cause of this had been too much conversation with friends on the evening of a holiday. Massage of twenty minutes to the head alone, in the evening, almost completely relieved the headache and neuralgic pains, and was followed by an excellent night's sleep. After this massage, of the head, with resistive movements to the muscles of the neck, was repeated seventeen times in twenty-four days, and the improvement in sleep, in comfort of the head, and in the power of using his mental faculties was so great, that it became a serious question whether he should not abandon a six months' sea-voyage that he had engaged. Marks of improvement that may be mentioned were: that when he had an occasional wakeful night, he felt no worse on the following day; he had none of his former anxiety in taking charge of his class in Sunday School; he attended a large party late one night without any after-effects, and he walked about freely, and all while he was preparing for an absence from home of six months or a year. Medicine had been laid aside before massage was tried in this case.

Case II. Rev. D. L., aged sixty-six years, has a good appetite and is well nourished, weighing about one hundred and eighty pounds. For twelve years, he had suffered much from wakefulness. He required from eight to nine hours of sleep, but seldom got more than five or six hours of broken, unrefreshing slumber. At times he would fall asleep soon after retiring, to wake up in a short time; at others, he would lie awake for hours before getting to sleep. Besides discomfort about the head, he had still more distressing dull aches and uneasy sensations in the lumbar region, aggravated by study or wakefulness.

He found some relief from giving up his ministerial duties ten years before I saw him. He came to me on the 25th of January of this year, and, after thirty-five minutes of massage on his head and back at noontime, he passed the remainder of the day in comfort, and that night and the following had seven hours of sleep each, so that when he came to me on the second day after massage he was hopeful and radiant. Massage was repeated at 11 A. M. on head and back, with increase of comfort to the patient. He did not sleep so well the following night as he did the two preceding nights, but he realized that he was quiet and serene, and felt that he was resting, and next day was refreshed. This day he had a refreshing sleep of an hour and a half in the afternoon, which he never could obtain before when well, and that night slept steadily for seven or eight hours. This patient had massage three times weekly, at or near noon, for seven or eight weeks, and the result of the first week is a fair average of the succeeding weeks: five good nights of sleep out of six, with a nap of an hour or two in the afternoon; and, when wakeful, he felt that he was resting, and, the following day, was not miserable from loss of sleep, as before massage; vigor of body and mind gradually increased, and he could take part in lectures, sociables, and other evening entertainments without loss of sleep, as formerly. Mild tonics and stimulants always made this patient worse. An epiphora that had troubled him for many years disappeared under massage of the eyelids.

Case III. Mr. E. B., thirty-five years of age, had been in good health for several years, and attended to his business, which involved great detail, from 9 A. M. to 6 P. M., with an hour off at noon for lunch. He had remained in the city all the previous summer, and felt very well when he went away for a vacation of several weeks to Colorado, returning on the 20th of November. From the time of his return he began to suffer from headache, which caused him to be out of his office several hours daily; and, by the end of three weeks, this became suddenly so much worse that he was obliged to leave his office altogether. There was a slight elevation of temperature, but still he had a good appetite, and slept well. I gave him massage of the head on three successive days, and the headache was relieved only while the head was being manipulated, and for a short time afterwards. When massage was being done on the right side of the head, the ache would disappear and increase on the left side; and, on doing both sides they were relieved, and the ache increased in the back of the head; and, on *masséing* the back of the head, the discomfort would disappear from there and increase in the forehead, and, on manipulating this region, it would disappear altogether for a time. In other cases, I have chased pain in this way all over the patients without being able to dislodge it completely, only temporary relief being afforded at the place of application.

Case IV will serve to show still further that it is

not always well for those who are inclined to nervous exhaustion to give up their employment when working easily, and go away on a vacation. Miss M. P., thirty-four years of age, teacher in a High School, had been subject to headaches all her life. Her parents had highly nervous temperaments. One year before I first saw her, the headache had been so severe that she was confined to bed for seven days with pains all over her and elevated temperature, and since then the headaches have been more frequent and more severe than before, and usually accompanied with nausea and vomiting. Evidently, the case was one of migraine. The ache was on the left side of the head, in the left eye and more especially over the left temporo-parietal region, accompanied with a crawling sensation at the back of the head, and soreness of the muscles of the back of the neck. The left side of the face was smaller than the right. She had great weariness and weakness in her arms, so that it tired her even to raise them. In the cervical and upper dorsal region, there was much tenderness on pressure over the spinous processes. Her appetite was good, bowels regular, and she slept well. Notwithstanding the increase in frequency and severity of headaches for a year, she had gained in weight, mainly adipose, so that she weighed one hundred and sixty pounds, her ordinary weight being one hundred and twenty-three pounds. She continued her duties as a teacher, and found that she felt better when occupied in this way than when not feeling compelled to do anything. Saturdays and Sundays were her poorest days, and a vacation of two months in the South ten months before she came to me was of no apparent benefit to her, but, she thought, made it all the harder for her to begin her professional duties again. Correcting examination-papers fatigued her more than anything else. She could walk three or four miles with ease.

The first massage of thirty minutes on the head alone left this region "perfectly comfortable," until the second massage was repeated, two days later, when this comfort was extended to the manipulated regions — head, neck, arms, and shoulders — and a burning sensation between the shoulders was also relieved. In four weeks, a continual wooden, numb sensation of the left side of the head was not only relieved temporarily, but did not return; and, corresponding objectively to this, her tough, indurated scalp had become soft and supple. Sixteen days after she came to me she could not stand and read on account of weak and uneasy sensations in the back of her neck, as if her head would drop backwards when she attempted to hold the book, but she could sit and read with ease. This was at the catamenial period, when she was generally worse in every way. But, two days later, she was much surprised to find that she had recuperated more quickly, and to a greater extent, than ever before. This patient had massage twenty-five times in ten weeks, with increasing improvement, and this continued after treatment was omitted, so that she was practically well — sufficiently well to enjoy her summer vacation, which helped to confirm the benefit previously received. Six months later, she reported that she had continued quite well. The following spring her troubles returned in the same way, but less severely than formerly. They were speedily removed by massage, and staid away for a year, when, again, there was a slight relapse, and more speedy recovery under massage. At times, she had found nux vomica more beneficial than any other internal remedy, but even this had lost its effect before massage was tried.

CASE V. Mr. J. B., aged thirty-three years, has always been a nervous man. He often felt fatigue in the lumbar region, but this he regarded as a matter of course, and he was always capable at business until six years before I first saw him. At that time he was in an elevator which was being tested against sudden falling by means of some "sure patent preventive." The experiment failed, and the elevator fell eighty feet with six men in it. While descending, our patient sat as tailors do, hoping thereby to diminish the shock of stopping. He got out apparently none the worse, walked four squares to his newspaper office, for he was then an editor, and dictated an account of the accident. He staid at home for five or six weeks, but was not confined to bed. After this he resumed his duties, but it was eight months before he could walk a mile. For a long time, in the evening, the region of the spine was painful, but relief was often found by pouring cold water upon it; at other times, from very warm water. During vacation he was perfectly well, and played lawn tennis. For three weeks before I saw him he had suffered from pain in his back and legs, and could walk but a very short distance at a time. Conversation and reading quickly tired him, and part of either would escape his attention. A few hours at business would cause nausea and headache, and make him feel generally used up. Appetite, bowels, and sleep were in a normal condition.

At my first interview there was much tenderness on pressure over the spinous processes and muscles of the back; but, after three massages in nine days, they could be manipulated quite vigorously. After six massages in eighteen days, he was practically as well as ever. Manipulation was exceedingly agreeable to this patient, and, while it was being done on either leg or hip, the agreeable sensation was felt in the back and in the other leg and hip, as well as at the seat of application. About once a year, usually in fall, after his vacation, this patient finds himself used up, as just described, and he has learnt by experience to rely on the prompt relief afforded by massage. He has also found wine of coca of some use. I have frequently made similar cases worse by using massage too vigorously to begin with.

CASE VI. When Mrs. M. W. came to me in October, 1884, she was fifty-eight years of age, and weighed 213½ pounds. Her adipose tissue was supple, and of good consistency. She had then been suffering for three years from a continual, distressing feeling of weakness in the right leg and thigh, which first made its appearance when there was some enlargement of the internal saphenous vein, but this had long ago disappeared. On examination, the whole limb seemed normal in every respect. The patient was not at all of a nervous, hysterical, or imaginative temperament, having been at the bombardment of Fort Sumter, once in a steamboat explosion, and once made a long voyage in a vessel with the cargo shifted, so that there was imminent danger of the vessel upsetting, besides having travelled twice round the world, on one of these occasions taking command of a vessel for four weeks amidst shoals and breakers in the China Sea.

A walk of a square was as far as the patient could go with comfort, and a walk of one-fourth of a mile caused great fatigue, and increased the feeling of

weakness. She had tried absolute rest for one, two, and three months at a time, during which she lost flesh, but the limb did not improve. At my request, she omitted potatoes, sugar, and butter from her diet, and began walking for two minutes every hour during the day, which was increased daily one minute every hour. Massage was given to the leg, thigh, and hip three times weekly. The first time it comforted and rested the limb, and after this passive and resistive movements were also given, which at first tired the limb, but this was at once counteracted by manipulation. At the end of two weeks she could walk half a mile without fatigue — twice as far as she could before with great fatigue — and a distressing pain that previously came after slight exertion at the exit of the sciatic nerve had not been felt for a week. At the expiration of four weeks the patient walked a mile and a half with ease, feeling but slight general fatigue thereafter, and the limb that had been weak was not so tired as the other. It was by her own wish that massage was repeated occasionally for a few weeks longer, and she has continued well ever since. Under the restricted diet she lost seven and a half pounds, and no doubt but this aided her recovery.

Case VII. Miss E. H. was thirty-nine years of age when I attended her in the winter of 1883–84. She is irregularly astigmatic, and suffers from headache, and this is worse at the menstrual period, which recurs every three weeks and a half, accompanied with pain. She suffers much at times from indigestion. She is a lady with a strong mind, a clear intellect, an unwearied conversationalist, and, in the language of her physician, who sent her to me, "she is a preëminently hyperæsthetic subject, and would be hysterical, did not the brain govern the *cerebrum abdominale*." For five years she had suffered with pain in her right knee, impairing locomotion, and, the latter part of this time, there was pain also in the outer and posterior aspects of the thigh, where the muscles were considerably atrophied — so much so that her other discomforts seemed small in comparison with those of the limb. The trouble in the limb came when she was run down from nursing a sick relative, and, coincident with this, a severe cough that had been increasing every winter disappeared, and did not return. During these five years under rest, with and without fixed dressings, changes to country and seashore, the use of tonics and sedatives internally, and blisters externally, there would be sometimes a little improvement in the knee, but always followed by speedy relapse on slight or no provocation, such as accidentally hitting it against something, or being obliged to use it a little more than usual. At times, the pain was relieved by walking; at others, made worse. It was aggravated by cold weather and by riding in a carriage.

Examination showed that the affected limb was much smaller than the other, the skin cold and dry, the muscles atrophied, but there was nothing especially noticeable about the knee, save slight puffiness and great tenderness on pressure upon the internal condyle, not in the skin. Owing to pain and weakness, which were aggravated by walking, she could take but a few steps when massage was begun, and the only symptom then in her favor was steady sleep. Massage was applied three times a week for eleven weeks and a half, being omitted for a few days at one time, on account of unusual pain in back, stomach, and intestines. For the first four weeks, massage, with gradually increasing exercises, was confined to the affected limb, with the result that she was, at the end of this time, taking four walks daily, of ten minutes each, besides exercises of standing on tip-toe, stepping up two steps at once, holding the limb out extended, and elevating it sideways when lying down. From the first, the skin became warmer, softer, and suppler, and the muscles fuller, as shown by an increase of one-half inch around the calf; one-fourth inch at the knee; one-eighth inch three inches above the patella; and one-fourth inch seven inches above the patella. When treatment was discontinued, these gains were one-half inch, five-eighths, three-eighths, and seven-sixteenths, respectively. But at the end of four weeks the pain was still about the same, notwithstanding the improvement in locomotion, nor had it entirely disappeared when massage was given up.

As soon as she made known the head and abdominal troubles, massage was applied for ten minutes to each of these regions also, which was during the last seven weeks of treatment. Headache was improved, sleep became more refreshing, digestion easier. During the last eight or ten days of treatment, it became evident that, though the patient was much better, and could go about much more freely on foot and in a carriage, she had come to a stand-still, and consequently the treatment was terminated rather sooner than she wished. A year later I saw her and she was the picture of health. Her appetite was enormous and digestion good. She had gained many pounds in weight and could walk freely, but still suffered from headache. She considered, and I think rightly, that massage had given her a start, and improvement had continued since it was omitted, for no other treatment had been used.

Amongst people who may be considered perfectly well, there are few, if any, who have not some weak points. When fatigued or worried I suffer from tension and dull ache throughout my whole right side. In September, 1884, when in Paris, I had one man give me half-an-hour's massage on my right side only, at 2 P. M., and another half-an-hour's massage on the same side at 5 P. M. The manipulation was slight, superficial and rapid and at the time of its being done seemed very ineffectual. But that night I never slept so sound in a railroad-train in all my life, as I did from Paris to Calais, and while crossing the channel I was not even sick. Two days later I played deck quoits all one afternoon when the themometer was 80° in the shade and the ship rolling. Next morning my playmates could scarcely get out of their berths, they were so stiff and tired, and so was I, but the fatigue was all confined to my left side and not to the right as formerly.

It may be said that these were not very sick people, but they are cases that prove troublesome to physicians, and they were certainly in conditions which any one of us would gladly be freed from. It is not necessary that I should dwell upon extreme cases of nervous prostration that have been treated by absolute rest, forced feeding, massage and electricity. I could give further details of the above-mentioned cases and also of similar ones which would seem to justify the following conclusions:

(1) That massage induces sleep.

(2) That even when massage is applied in the forenoon its soporific effects may not disappear before bed-

time; though in general the later in the day massage is used for promoting sleep the better.

(3) Disagreeable feelings of drowsiness and languor do not necessarily intervene between massage in the forenoon and sound sleep at bed-time. Aptitude for rest or work generally follows massage.

(4) When people are wakeful after massage they may not be restless nor feel the loss of sleep on the following day.

(5) Spinal irritation is relieved or disappears under massage.

(6) For local neurasthenia there is no need of general massage, unless the whole system be secondarily influenced.

(7) When affections have come to a stand-still under massage, improvement may yet go on after massage has been discontinued.

(8) For improving the nutrition of nerves and muscles, restoring natural sensation and motion, massage may succeed when other means have failed.

(9) Deep massage without friction has proved of more value in my hands than all other forms of massage put together, in the cases herein considered.

(10) Massage can be overdone, producing opposite effects from a moderate application.

(11) Besides massage, carefully-graduated exercises at regular times, are valuable accessories in the restoration of motion.

(12) Massage is not the only means of treatment for neurasthenia. Its selection is usually decided upon after the failure or exhaustion of every other means; in the same manner that the shrewd old divine decided that it was not wise to let the devil have all the good times to himself.

A CASE OF CHRONIC PANCREATITIS, WITH SYMPTOMS RESEMBLING MALIGNANT DISEASE.

BY E. L. CALL, M.D., BOSTON.

MRS. B., age sixty-two, widow, was first seen February 24, 1886. She was of medium height and weight, her skin was sallow, and her countenance haggard and anxious. Her habits of life were regular and her hygenic surroundings good. She said she had been well till within the past three or four months, but more searching inquiry showed that her appetite had been very capricious for a number of years and that during the last year she had lost strength and a moderate amount of flesh. Her diet had been mostly of the saccharine and starchy foods, as she had always disliked meat. For the past few months physicial exertion of any kind had tired her out of due proportion, and during the last few weeks even moderate exercise had been followed by breathlessness and beating in the arteries of the neck. There was complete anorexia, and the bowels were very constipated.

The physicial examination was as follows: Skin, a muddy yellow; tongue, rough, slightly coated; lungs, normal; heart, normal in size and position, moderate blowing murmur throughout the cardiac area, most marked over the base; abdomen, normally resonant; liver dulness, normal; no increased spleen dulness; pelvic organs, normal; urine, normal.

[1] Read before the Section for Clinical Medicine, Pathology, and Hygiene, of the Suffolk District Medical Society, November 9, 1887.

In consequence of the negative result of the examination, the case was regarded as one of profound anæmia, and the treatment was directed toward regulating the bowels, and assisting nutrition easily by digestible food and some of the most assimilable forms of iron.

The gravity of the symptoms increased rapidly; the simple act of rising from her chair caused dyspnœa, food of all kinds was very repugnant, the skin grew more sallow and the feet œdematous. She vomited occasionally, especially after any unusual movement. Temperature 100°; pulse weak, 90 to 100. This rapid change for the worse made me feel that the case must be either one of pernicious anæmia or some concealed organic disease, and I therefore asked for a consultation.

Dr. R. T. Edes saw the patient with me, March 16th. He did not think the anæmia profound enough to warrant a diagnosis of pernicious anæmia, but as he could find no proof of organic disease, he advised full doses of liq. pot. arsen., and gave a very guarded prognosis. A microscopical examination of the blood showed the red corpuscles notably diminished. No increase of white corpuscles and none of those irregular forms of red corpuscles characteristic of pernicious anæmia. The patient was kept in bed and fed per rectum as well as by mouth.

She improved for a time under this regimen, the dyspnœa becoming less troublesome so that during part of April and May she was able to go down stairs and to ride out occasionally. In fact the dyspnœa did not trouble her again to any amount till just before her death. I never felt, however, that the improvement was permanent, for her color remained bad, and she did not gain flesh nor appetite.

Early in July she complained of fluttering in the epigastrium and her distaste for food wasso great that only the force of a strong will enabled her to eat or drink. The abdomen was again examined, slight increase in liver dulness was noted.

On August 16th, she had a sharp attack of hepatic colic followed by intense jaundice and so much nausea that she was fed entirely by rectum for five days. She rallied very slowly and now began to lose flesh quite rapidly.

On the fourteenth of October she had another attack of hepatic colic, and passed a gall-stone the size of a pea. After this the signs of digestive disturbance were more marked. She complained constantly of a burning pain under the lower end of the sternum coming on about two hours after eating. She also complained of a feeling of weight in the bowels when she sat up as if some heavy body were dragging from the spine. As she was certainly the least nervous or imaginative person that I ever met, these symptoms deserve more attention than they would in ordinary cases.

The bowels were either constipated or relaxed. The stools varied, being sometimes perfectly normal in appearance, sometimes sticky and putty like, sometimes gray in color, often they contained undigested food. Throughout her illness every stool was examined by her daughter, an unusually intelligent lady, and I saw many of them myself, but never could see or hear of any of the fatty stools considered to be characteristic of pancreatic disease.

Early in February, she began to vomit irregularly and complained constantly of distress after eating. She never had another paroxysm of hepatic colic, but

she grew deeply jaundiced, vomited constantly for five days, the feet and limbs became œdematous, the pulse rose to 120, and death seemed imminent.

During all this time no tumor of any kind could be felt in the abdomen, nor was there any tenderness nor tympanites except just after the attacks of colic. It seemed to me, however, that there must be some disease, probably malignant, in the region of the duodenum, liver or head of the pancreas, but wishing to get all the light that greater experience could give, I asked Dr. M. Wyman to see her with me. Dr. Wyman thought the case was either one of pernicious anæmia or malignant disease, probably the latter.

The vomiting gradually ceased and she rallied slightly again, and from this time January 4th, till her death February 14th, it did not recur to any extent. She now began to suffer from what she called "nervous twitches." She insisted that she had no pain, but she lay as if prostrated, moaning with every breath, her features pinched and deathly pale. In fact, her appearance was exactly as when she was suffering from hepatic colic, except that there was constant twitching of the feet and legs, and occasionally of the arms. These movements were to a certain extent, but not entirely, under the control of the will. The attacks came on at first only occasionally, but they grew more and more frequent, until during the last two weeks of her life, it was necessary to keep her constantly under the influence of sedatives to give her any rest from them. She grew gradually weaker, and died February 14th.

Autopsy, twenty-six hours after death. Rigor mortis well marked. Skin a dirty yellow. Body and limbs much emaciated. Owing to circumstances which so often hamper the performance of autopsies in private families, I was only able to examine the abdominal cavity.

The muscular layer of the abdomen was very thin. The abdominal cavity contained a small amount of clear serum. The intestines looked very anæmic. The small intestines were contracted, the large intestines unusually long and somewhat distended, the walls in some places so thin as to be almost transparent. No trace of peritoneal adhesions or inflammation.

Liver slightly enlarged, rather pale, yellowish, surface perfectly smooth but rather firm in texture.

Gall-bladder the size of a large pear containing three large, and many small gall-stones. Bile very dark and viscid.

Stomach empty, walls very thin; not the slightest appearance of malignant disease in the stomach or duodenum. Upon raising the stomach the pancreas was seen, larger than normal, dark gray in color and so firmly adherent to the vertebræ and posterior abdominal walls that it was detached with great difficulty. The attachment to the duodenum was also over a larger surface than usual; the gastro-splenic omentum much thickened. Upon removing the pancreas, it looked so large and firm that I felt assured that there must be a deposit of cancer in the head and that the diagnosis of malignant disease was correct. The specimen was placed in alcohol for further examination, but it was, found impossible to harden it; in fact it grew softer, and large quantities of fat seemed to have been dissolved out by the alcohol and floated upon the surface. A microscopical examination, in which I was kindly assisted by Dr. Blodgett, showed a large increase of connective tissue, an abundant deposit of pigment, with very little trace of acini or glandular epithelium, a considerable amount of fatty degeneration. The specimen, as I show it to-day, gives a very poor idea of its appearance when removed from the body. Its size has diminished at least one-half, by its seven months' immersion in alcohol, while the texture is softer and more friable. The portion of duodenum attached shows the opening of the ductus communis and the canal of Wirsung. The gall ducts are dilated very much. The opening of the portal vein is seen toward the head, while the superior mesenteric artery runs along its posterior surface and the splenic along its upper border.

I bring the case before the society as one of pancreatic disease, although I am quite aware that it may be an open question how far the condition of the pancreas was answerable for the symptoms. There is so little known of the pathology of this organ, that it seems right that every case in which an abnormal condition is found, should be recorded. Almost all reported cases are those of carcinoma, in which it is very difficult to separate the symptoms common to many carcinomatous growths, from those due to injury of the gland. Moreover, in most of these cases the disease has extended before death to neighboring organs.

Experiments of removing or destroying the pancreas in animals, show diverse results. While in some, rapid emaciation, fatty diarrhœa, and death from inanition, rapidly follows, in others the pancreatic secretion seems to be replaced by some other digestive fluid, so that the nutrition of the animal suffers very little. This is notably the case in the experiments lately published by Senn in his articles on "Surgery of the Pancreas."

The chief symptoms supposed to indicate pancreatic disease are rapid: emaciation, jaundice, diarrhœa and constipation, fatty stools and cœliac neuralgia; but no one of these symptoms seems to be invariably present, and only one, the fatty stools, pathognomonic. In about twenty-five cases which I have been able to collect of disease of the pancreas, mostly malignant, in only two were the fatty stools prominent, though doubtless in many, search for them was not made, as the disease was not diagnosed before death.

A symptom mentioned by Friedreich, in "Ziemssen's Handbook," and by Starr in "Pepper's System of Medicine," is a feeling of weight in the epigastrium, particularly on assuming the erect position, as if a heavy body were pulling from the spine. This symptom was constantly complained of by my patient, so long as she was able to sit up. I cannot help thinking that the paroxsyms of nervous distress which were the cause of so much suffering to her were some form of nervous disturbance produced by pressure on the nerve structures surrounding the pancreas, and were analogous to the attacks of cœliac neuralgia mentioned by many authors.

Although all writers on pancreatic disease describe a chronic hyperplasia of the connective tissue of the pancreas as one of its diseases, I can find the record of only one case which seems somewhat similar to the one I have here described. This was reported by Dr. Tyson in the *Philadelphia Medical Times* in 1882. The case was that of a lady sixty-eight years old who had always been well until an attack of pneumonia in February, 1880. From this time she had more or less disturbance of the bowels. In July, 1881, she was seized

with severe diarrhœa and clay-colored stools. This was quite persistent, and accompanied by irregular distention of the abdomen apparently from areas of flatus. Later, a small indistinct lump was discovered below the umbilicus and to the left. The diarrhœa continued, and the stools were distinctly fatty. She emaciatied rapidly, and died March, 1882.

At the autopsy, the lump had disappeared behind the stomach, but was found to be the head of the pancreas, which was unusually resisting but not much enlarged. Upon examination the secreting structure of the pancreas was found to be nearly all atrophied, and its place occupied by a fibrous tissue. In this case, also, the organ was so much shrunken and altered by the preserving fluid as to present a far less striking appearance than when removed from the body.

But in addition to the condition of the pancreas itself, I wish to call your attention to the parts surrounding it, as it seems to me that we may find there an explanation of some of the symptoms not otherwise accounted for. The adhesions between the head of the pancreas and the vertebral column were so firm, that I was obliged literally to dig the gland out of its bed. The connective tissue seemed almost leathery in its toughness and resistance.

You will remember that the cœliac axis gives off its branches just at the upper border of the pancreas, the semilunar ganglia of the solar plexus lie partially behind the gland, while the superior mesenteric is given off from the aorta just at its lower border. In this case, as will be seen by the specimen, the superior mesenteric is given off above the pancreas, and runs across its whole posterior surface, and therefore could hardly fail to be compressed between it and the spine, where the adhesions were so firm as in this case. Even a moderate amount of compression on the artery supplying the whole of the small intestines, would probably modify their nutrition, and render their digestive fluid unable to supply the want of pancreatic secretion, as it probably does in some cases. The semilunar ganglia would be even more easily compressed than the arteries. Since they are the sympathetic nerve-centres which modify the nutrition of all the organs of digestion, any injury to them would probably affect the proper performance of the function of those organs.

There is no doubt that the attacks of hepatic colic were instrumental in hastening the fatal termination of the case.

I suppose it may be asked whether this was not really a case of pernicious anæmia, and the condition of the pancreas, etc., only a secondary result of the anæmia, instead of being its cause. Against this, speaks the age of the patient, her comfortable circumstances and regular life, the high degree of emaciation, the absence of fever, and the fact that at the autopsy, the organs though anæmic, had not that absolutely blanched appearance, described as characteristic of pernicious anæmia.

I hope, however, that those who have had more experience than I have in this disease, will give the Society the benefit of their opinion on the question.

— The following epitaph is "said to" have recently been placed on the grave of a dentist in London:

"View this gravestone with all gravity
J —— is filling his last cavity."

Clinical Memorandum.

A CASE OF CALCIFICATION OF THE AORTA.

BY FREDERICK W. TAYLOR, M.D., OF CAMBRIDGE, MASS.

MRS. B., aged sixty-three years. Had enjoyed fair health, and had always lived in comfortable circumstances. Her father died suddenly, the cause said to have been apoplexy. Two uncles died while suffering from gangrene of the toes. One sister died in an insane asylum; another sister is living, but is said to be "fussy and nervous"; a third, much younger than Mrs. B., is in good health; one brother has hemiplegia.

September 18, 1887, Mrs. B. was in a small boat, fishing, between three and four hours. After returning home she ate a hearty dinner, but felt no discomfort from it during the evening. She passed a rather restless night, and the next forenoon had pain in the epigastrium and vomited, throwing up the food she had taken the day before. Abdominal distress and retching continued severe, and were relieved during the afternoon only by large and repeated doses of morphine.

September 20th. Patient comfortable, sleeping most of the time. The pulse remained high as compared with the temperature, not falling below 120, and at times being 140.

September 21st. Objected strongly to taking nourishment. In the evening, temperature, 98.5° F.; pulse small, 120; face pale; epigastrium tender. During the next two days she took nourishment, was comfortable, and gained strength.

September 24th. In the forenoon she walked from the bed across the room and urinated, as she had done several times before, thinking to defecate also, she remained upon the chair straining, when her feet began to prickle and be painful; she was assisted to bed; the unpleasant sensations extended to the thighs; the limbs were at once rubbed, when it was discovered that they had lost all tactile sensation; they soon became cyanosed, and circulation in them entirely ceased. Both lower extremities were equally affected. Great general distress followed, which was only relieved by large doses of morphine and brandy.

September 26th, A.M. Temperature 95°, pulse 120; mind clear; skin cold and moist; lower extremities very rigid, as if in extreme rigor mortis, and cyanotic except a small portion outside of the thighs. At the junction of the living and dead flesh there was great sensitiveness to touch and motion. Progressive failure till death, which took place at 12 o'clock the night of September 29th–30th.

AUTOPSY. October 1st, 40 hours after death. Body fairly nourished. Portions of skin of legs and thighs bright red, but no advanced decomposition; limit of redness at upper part of thighs very distinctly defined.

Heart. Dependent portion very dark red; right side filled with dark, soft clots; small atheromatous spot in rim of left auriculo-ventricular orifice, but no ulceration over it; curtains of all valves normal; no indication of endocarditis or cardiac thrombosis.

Aorta. Very firm calcification of anterior wall from the bifurcation into the common iliacs upward two and a half inches. At this place was a complete, ly obstructing adherent clot, with prolongations into the iliacs. The upper portion of this clot (about an inch in length) was firm and light colored; the lower

portions and the prolongations into the iliacs were darker and less firm; between these portions was a third, measuring one-half to three-quarters of an inch in length, and occupying the entire calibre of the aorta, which was very soft and dark red.

Other organs were normal as far as examined.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

Regular meeting, at 19 Boylston Place, Wednesday, November 9, 1887.

Meeting called to order by the Secretary, Dr. Albert N. Blodgett, at 3.00, P.M.

A ballot for President of the Section for the coming year resulted in the choice of Dr. A. L. Mason.

Dr. Mason not being present, Dr. V. Y. Bowditch was chosen chairman *pro tem.*

On motion of Dr. F. H. Hooper, a vote of thanks to Dr. F. I. Knight, the retiring chairman, was passed.

Under the head of incidental business, Dr. Blodgett read a note which had been sent him by a member of the Society, in which was a complaint that due notice of the meeting of the Section had not been received. In explanation of the fact, Dr. Blodgett said that the delay had been caused by an unexplained delinquency of the mail service, whereby the proofs were several days on the way from the mail-box to the printer. Every effort had been made to get the notices out in season by having a large corps at work directing them, and in the haste some names may have been inadvertantly overlooked. Dr. Blodgett was very glad that attention had been called to this matter, as it showed the interest which was felt in the meetings.

The Secretary then read a personal communication from Prof. F. W. Putnam, of Cambridge, to Dr. Bowditch, giving an invitation to the members of the Medical Society to inspect the relics which have been collected in Cambridge relating to the subject of American Archæology, and to listen to a talk upon the subject of the recent explorations.

Dr. Knight said: It certainly is not necessary to say a word to any one who has ever heard Professor Putnam, in regard to the interest of his communication, in whatever line he may choose to make it. It will be certainly a very interesting thing for every medical man, and I propose, sir, that the Secretary be authorized to make arrangements for a meeting in the Museum in Cambridge on some Wednesday evening when there is no Section meeting. I would suggest that the invitation be extended to all the Suffolk District Medical Society. The motion prevailed.

The Secretary then asked when the report of the committee which had been instructed to look up the matter of the milk-supply of Boston, would be ready.

Dr. Cushing replied that the report had been made out and signed, and would be submitted at the next meeting of the society.

Dr. F. O. Otis read a paper entitled:

HINTS TO PHYSICIANS SENDING THEIR PATIENTS TO COLORADO.[1]

Dr. F. I. Knight said: I certainly agree with all that Dr. Otis has said about the climate of Colorado, as far as I know it. I think we ought to be very much obliged to him for the details he has given us in regard to the points which many physicians certainly do not understand. There is another point which ought properly to come up, although Dr. Otis did not feel necessitated to notice it in his paper. I think a warning ought to be given, whenever the subject comes up for consideration, at any rate when it is presented to those who are not familiar with the subject, in regard to the cases which are to be excluded from that climate.

It is too much the fashion, when a climate becomes popular for the relief of any disease, for all patients with that disease to be hustled off there. And this is just as much a mistake as it is for every case of pneumonia to be treated with the same drug. It is very much like the treatment of disease with a little book of symptoms.

There are certain kinds of consumption that will die very much quicker in Colorado than they would if they stayed at home, and it is certainly very much wiser for a physician, unless he has considered his case for a long time, and perhaps has counsel upon it, to keep at home cases of very advanced disease; also, to keep out of that climate cases attended with a good deal of fever, and very possibly, also, those cases of a highly wrought nervous temperament. To be sure some of these latter cases do well in Colorado, and some even of the advanced cases.

One case I have in mind, which was taken out there without my consent, not exactly against my remonstrance, which after a long time did do well, although it was a case of very advanced phthisis. As a rule, it is very much safer not to be in haste, at any rate, to send these cases to a high altitude. It certainly has been my experience, and I have had cases of pulmonary disease treated in almost every climate in the world, that the cases of lung disease which are free from fever, and where there is tolerable strength and constitution to start on, do far better in a climate of that kind, a high mountain climate, than in any other; and I think that all climatologists are fast coming to that opinion.

In the cases of very advanced disease, in those cases particularly where there is a good deal of febrile disturbance, it is possible that after a time, after the activity of the disease has been mitigated at home, that patients may be removed there with safety; and this is a thing for consideration.

There is another point which we must also bear in mind, which must be urged upon the minds of men, that in regard to it they may not act hastily, and that is in sending poor patients off there with the idea that the climate is going to do everything for them. As a rule, if a man has extensive disease of the lungs, and is going to work for a living, he had better be advised to save his money and stay at home. He had better do as well as he can among his friends, and not waste the little that he has accumulated in a change of climate, for his money will go in a very short time out there, and he will be left stranded and unable to

[1] See page 569 of the Journal.

work. It is a great pity, it seems to me, to send off, as some physicians seem to be in the habit of doing, every case of pulmonary disease, without regard to their circumstances. Almost every day cases come to me who have been urged to go to Colorado or California, or New Mexico, patients who have perhaps accumulated a few hundred dollars, which is all they have in the world, and they are advised to make a change of climate on account of lung disease. They would be left stranded. I should say that unless the patient had very little disease, and it was perfectly clear that he was able to work, and certainly it is not so with the most of these cases, they would better be advised to stay at home, unless they have means of living a considerable time without any active work.

DR. ALBERT N. BLODGETT said: Mr. Chairman, I had an opportunity, some years ago, of investigating the climate of Colorado, although not so extensively as Dr. Otis has done, and I was struck by one or two things that have been mentioned, and some that have not been alluded to. In the first place, the distance is so great that many patients who start in fairly good condition are very greatly fatigued by the journey. Under any circumstances it is extremely taxing for an invalid. The journey is a long one, and I think that, with ordinary expedition, a week would be thus consumed. I have seen patients who, from fatigue, have seemed to die sooner there than they would have done if they had remained at home.

I have supposed that cases in an acute stage of pulmonary phthisis should not be sent to that climate. I think the abruptness with which the change would be made, and the high altitude reached, for persons whose pulmonary structures have been invaded by phthisical disease, is a question which should have more consideration than is usually given it. I have seen healthy persons suffer from shortness of breath on arriving in Colorado to such a degree as to make any sort of exercise burdensome for some days. I have seen others, in Switzerland, who have had a rush of blood to the head, in an altitude as high as Colorado Springs, which was relieved by frequent nose-bleeds. I have seen the same thing in Colorado.

Perhaps it would be better to break the journey for the sake of lessening the fatigue, and also in the hope of accustoming the pulmonary structures which are already diseased, to the rarer air, rather than to make a hasty journey, and perhaps put a feeble patient in a less favorable condition for improvement than he would be in with a little more attention to this precaution. I can certainly verify everything that has been said, so far as my experience will go, in regard to the wonderful climate which is found in this part of our country. I had an opportunity of seeing a part of Colorado, although it was a very small part, located in the vicinity of Denver and Colorado Springs, and the parts between, and I never saw anything like the clearness of the air in this region. The exhilaration is something remarkable — certainly in a healthy person — and I have no doubt it would be the same, to a certain degree, in a sick person.

I cannot help thinking that the climate of Colorado is the nearest to a typical climate for consumptives which we know anything about; but I believe that far greater care is requisite in the selection of cases, and far more caution in changing to that climate than has heretofore been observed.

DR. H. O. MARCY said: Unfortunately I did not hear the first part of the paper, and possibly it may furnish a little wider range to the discussion if I should diverge to other sections of our country. I have had certain experiences in Montana, although Colorado I have not myself visited. The experiences of certain patients that have been sent from time to time to western ranches would correspond to what has been said. I think we are under obligations for the paper. It does teach us a good deal in reference to the classification of patients. If there be anything which my own experience would emphasize, it is in regard to the objection to sending patients into the wilderness away from home. There is a good deal of emphasis to be laid, too, upon the distance and the expense.

Two years ago I made a pretty careful study of the Appalachian range in Georgia. I believe there are certain of the Alleghany ranges which ought to be taken into consideration in sending patients from our own vicinity. There is the change in life, the distance in reference to diminished expense, and the expense of living after one is there. In the western sections there are a great many places where one may live profitably by making it home for investment. So far as elevation is concerned, there are valleys in certain sections up two or three thousand feet. This is inconsiderable in comparison with Colorado, but very considerable in comparison with other elevations. Eight-tenths is still primeval forest, which equalizes temperature.

It is not as dry a climate as Colorado. The rain fall is probably not less than in New England, though it is placed on the maps as being dryer than any other section — than the Colorado ranges. I saw a number of invalids who felt sure that they could not live on our sea-coast border, men who had cavities and had had hæmorrhages, and who were in pretty fair health. I have myself sent forty or fifty patients to this section, and, although they have different results, in the main it is as satisfactory as double that number of cases who have gone to Colorado. Ample board can be obtained with half the money. The expense of going is less than half, and sometimes a distinct advantage is gained in the fact of the invalid being much nearer home.

The air there is as pure as can be found in any part of the world. The mountain tops are covered with snow three or four months, the valleys only three or four days at a time. The locomotion is, on horseback, *par excellence*. Every other way is uncomfortable in the extreme.

DR. OTIS asked what special towns were recommended.

DR. MARCY: Ashfield is the centre. Its population has doubled within two years. There are several hotels there. Notably the Battery Park (?) Hotel. That is an expensive hotel; four dollars per day. But Ashfield furnishes very good accommodation at ten to fifteen dollars per week. Certain other places are extremely cheap. I spent a week in one of the little hotels. When I asked for my bill, I was told that a dollar a day was the regular price, but as I had been there a week four dollars would be enough. In Waynesville, hotels are springing up everywhere in answer apparently, to a legitimate demand which is being made as the country is becoming better known.

DR. R. W. GREENLEAF said: It was my good for-

tune to visit Colorado some summers ago, and while I should like very much to speak on the very great beauties of the place I think those have already been spoken of; but there are one or two medical questions relating to it in which I differ from what Dr. Otis has said. First, in regard to whether the patients who are sent there ought to go right about their exercise or not. It seems to me that it would be far wiser for them to remain at rest for some days. A well person is quite fatigued by the altitude, even in such a place as Colorado City. I was perfectly well all the time I was there, but even a half-mile fatigued me for some days; after that I could walk indefinitely as at home.

Instead of remaining in Colorado City or in the towns, where there are all the drawbacks of dust and residence in cities, why is it not wiser to advise the patients, if they can afford it, to go into the mountain regions and be in camp all the time? To be sure, some things are hard, but they can be lightened in many ways. Changes of heat and cold are very noticable. It was very warm at midday, and the water was almost frozen at night. It seems to me that it is far wiser for the patients to go into the mountains as soon as they are strong enough to undergo such extremes, so that they could be out of doors all the time. I was very glad to hear what was said about the selection of cases, for I met many cases who were coming back simply to die. It seems to me that it is a mistake to send other than select cases.

Dr. Otis said: I would like to say a word or two in answer to Dr Greenleaf. I did say that comparative rest is enjoined, and probably is essential. I did not mean to say that I believe in activity as soon as the patient arrives in Colorado Springs. It seemed to me that some of the patients, after they had been there a year, were sitting about on the veranda when it did seem as if they would do better if they moved.

In regard to the patient going at once into the mountains, the practical difficulty is that you cannot get good food. Unless he is pretty well and strong, the patient could not endure it.

I don't quite agree with what Dr. Knight said about poor people going out there. It seems to me it makes a difference what sort of a person it is. I remember one poor young man with no money, a clerk in a store. His employer gave him a present of fifty dollars, and he went out there. He had serious trouble with his lungs, and was told to keep still. He got a horse and rode about, and soon made friends with a cattle-man who employed him and paid him a fair monthly salary, and he seems getting on well. I remember another instance of a young man who had money enough to stay awhile, and found employment. He finally bought his employer out. I think it depends on the kind of man who goes.

Dr. E. L. Call then read a paper on

A CASE OF CHRONIC PANCREATITIS, WITH SYMPTOMS RESEMBLING MALIGNANT DISEASE.[2]

Dr. C. P. Putnam said: It seems to me that this case has been laid before us in a very interesting way, and that anything which adds to our very meagre information upon the pathology of the pancreas is most welcome. I suppose that in most instances where the pancreas is at fault other organs are at fault too, as in this case. In one case which is very prominent in my mind, where the pancreas was affected by malignant disease, the same disease was found in other organs of the body, notably in the liver. There, too, there were no fatty stools, and Dr. Call has mentioned that the fatty stools were prominent symptoms in only two out of ten cases. So that certainly the pathology of the pancreas seems to be more obscure, the more it is looked into. This case was seen by several physicians, and the disease was not suggested by any of them. The patient had a great deal of pain in the abdomen, but there was no reason to suppose that it came from the pancreas any more than from any of the other organs where the malignant disease was situated.

Dr. Knapp asked if any sugar had been found in the urine.

Dr. Call replied that repeated examination had failed in finding any.

Dr. Knapp asked whether any microscopical examination had been made to show whether the wasting of the intestinal and gastric walls was due to atrophy of the muscular coat simply, or whether it was an atrophy of the glandular tissue of the stomach and intestine.

Dr. Call: No examination was made, I am sorry to say.

Dr. Marcy: I have a case under care now that is, perhaps, worth reporting. It was at first supposed to be malignant disease of the abdomen. It has been under my observation for six months. He was a stout, robust sailor, never sick until six months ago, when he began to have slow wasting with vomiting and a whole series of symptoms, until last summer he had wasted so much that it was supposed to be a case of malignant disease. He was anæmic, pulse running up to one hundred by walking across the room. It was supposed to be a pretty clear case of obscure malignant disease.

About six weeks ago he began slowly to develop a cystic tumor in the region of the gall-bladder. Six days ago I made a laparotomy, stitched the gall-bladder into the wound, washing out about half a teacupful of pus and mucus. The hope was, although he had never been jaundiced, that something could be found. But, at about the head of the pancreas was a distinct bunch, about the size of the end of the thumb, hard and resisting. It remains to be seen just what it is. The inference is that it is malignant disease of the head of the pancreas. During these six days the patient has had relief. Discomfort of almost every type has departed. The temperature remains pretty nearly normal. I have no doubt it will go on to death, and perhaps in an autopsy we shall know more about it.

Dr. Douglas Graham then read a paper on

LOCAL MASSAGE FOR LOCAL NEURASTHENIA.[3]

Dr. Knapp said: These cases of Dr. Graham read almost like fairy stories. I would like to ask if he has any less favorable ones to report, or if they all terminate in this happy way.

Dr. Graham: I think we all see cases that are foregone conclusions from the first, and it is only a question of filling in time with them. They are bound to be treated any way, and I give simply cases that can be benefited.

Dr. Knapp: The same treatment seems to have been applied to the different cases. What cases are not suitable for this treatment?

[2] See page 576 of the Journal.

[3] See page 572 of the Journal.

DR. GRAHAM: I should regard extreme weakness as a contra-indication.

DR. PUTNAM said: On one occasion the suppleness of the scalp which was acquired by the massage was spoken of as one of the good results which affected the recovery of the patient, I should like to ask if the condition of the scalp was supposed to be a cause of, or intimately connected with, the disease of any organ.

DR. GRAHAM: The hardness might be the starting point for almost any reflex disturbance.

DR. PUTNAM: Do you think it was a prominent symptom?

DR. GRAHAM: It was one of the cases that are born neurasthenic.

DR. PUTNAM: It is very certain that manipulations upon the body do have great effects. Exactly what effects they have seems to be hardly determined.

DR. H. J. BARNES said: Dr. Graham speaks of one of his patients having extreme pain over one of the condyles. Not intimating the cause of that pain, have you any idea what caused it? Was it of a rheumatic nature?

DR. GRAHAM: I think it is of nervous nature. I suppose it might be called a hysterical knee-joint. The symptoms would not show sufficient disturbance there to account for the pain. I suppose you would call it nervous pain, if any one knows what that means.

DR. BARNES: I would like to know if massage will stop women from complaining of pain in the side when recovering from uterine trouble.

DR. GRAHAM: It might be relieved, but quite likely it would appear somewhere else.

DR. PUTNAM: Are these effects somewhat analogous to hypnotism, or are they to be considered purely mechanical?

DR. GRAHAM: I think the change comes from the improved circulation, the improved nutrition, and in some cases from the setting free of the nerve filaments so that the tissues may glide freely over each other.

DR. PUTNAM: I suppose some of the cases are connected with trouble in the cerebral tissues themselves. Do you think the massage has a reflex action upon the cerebral tissue?

DR. GRAHAM: Quite likely. Another instance where relief can be afforded is in cases of constipation from deficient innervation. Here massage should be applied to the back and abdomen. Sometimes, too, when the heart is irregular and there is shortness of breath. In one of these cases that was quite marked, I have seen temporary relief given while massage was being used. Of course he could not have it done frequently and I referred him back to a physician for a tonic which he could have oftener than the massage.

Also, there is muscular asthenopia, where great benefit was received from massage of the temples, eyelids and head. The resistant movements were quite a revelation to him the first time I tried them. No doubt it sends blood through the brain much more lively, and promotes absorption of lymph and effete matter. Communications have been demonstrated between the vessels and the spaces in the dura. Of course a quicker absorption would take place.

DR. PUTNAM: The doctor spoke of deep massage in diseases of the heart. Does he mean local in the region of the heart, or in the whole body?

DR. GRAHAM: In general; that statement has been confirmed by Dr. Eccles of London, in the June *Practitioner*.

DR. PUTNAM: I don't mean to throw any doubts on Dr. Graham's statements, but I think it is very hard to find a reason for the decided effects which are produced. I think that anything which would lead to the clearing up of the mystery would be a very interesting study.

OXYGEN TREATMENT IN PNEUMONIA.

DR. V. Y. BOWDITCH said: I wish to speak of a method of treatment which I have been using for the past two days at the Carney Hospital, which was very striking; and that is the inhalation of an oxygen compound, as manufactured by Dr. Walton, of Orange, N. J. About three months ago Dr. Walton came to my office with this preparation, which he claimed he should not put forth by advertising. He claimed that he had a purer preparation than had been placed before the public before. We all know the vaunted advantages of the compound oxygen. This preparation is said to have two atoms of nitrogen to one of oxygen. He claimed that the beneficial effects would be found in phthisis. I have used several tanks in that disease with negative results. I have been waiting for a disease like this.

Day before yesterday a man came in with very marked evidence of pneumonia in the lower lobe of the right lung. There was bronchial breathing; the respirations were sixty; there was marked cyanosis. I said, We have a case now. The man took a few inhalations. He had not taken it ten seconds before the look that came into his eyes spoke more than any words than can be uttered. In half a minute his respiration was fifty. The respirations had changed to comparative ease. The color also changed. I kept the tube in his mouth for about a minute, he breathing through the nose all the time, and so wasting the oxygen. When I removed the tube, I said: "Did you get relief from that?" And the whole look when he said "I guess so," was enough. I gave orders that he should take it every two hours. It carried down the respirations ten a minute. I had also put him upon aconite, a drop every hour. The next morning the pulse, instead of being 120, and bounding, was 98, and of good strength. The respirations had come down to forty, and, although the condition of the lung had not materially changed, yet the character of the respirations had entirely changed. I ordered the oxygen to be continued occasionally, and it has been kept up to the present time. I mention this because I think it can be tried by other physicians in similar cases. Metcalf & Co. are agents for the tanks, and I think have some still, although Mr. Metcalf told me the other day that he should discontinue the agency. I shall write him that I have had apparent success in this case, and that I think it would be well to continue it a little longer, and see if other physicians cannot have similar results.

Certainly if we have anything that will relieve the fearful distress it will be a great gain. The gas comes in cylindrical tanks, under a pressure of 250 pounds to the square inch, and one should last several days in a pneumonia case. It is simply passed from the tank through a wash bottle, and then into the patient's mouth.

DR. CUSHING: How long?

DR. BOWDITCH: I kept it in the mouth about a

minute. He was breathing through the nose all the time. He kept asking for the oxygen, on account of the relief.

DR. CUSHING: Is this gas any different from what a mixture with air would be?

DR. BOWDITCH: I cannot say. He claims it a mixture of oxygen.

DR. CUSHING: As long ago as when King Humbert died it was tried. I think it has been considerably used in Italy and Germany. It is given mixed with the air in a bag.

DR. MARCY: For a number of years I have been using oxygen for this purpose. I have not felt that it was a curative thing. I use gas from the calcium-light company. They have made a gas which they sell for three dollars a tank, and which is always ready. I use those that are used for the oxy-hydrogen light. I have been in the habit of letting the gas from the tank through the tube, and the patient breathes as he pleases. I have never seen any bad effects.

DR. BOWDITCH: I don't think it has any curative effect, only that it is a means of relief.

DR. MARCY said: My own impression is that it would be of great benefit if used early. The moment the patient has very much discomfort let him have the oxygen. I would gladly recommend it, but was disappointed in not meeting with better results.

Meeting adjourned.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, November 21, 1887.

DR. DANIEL BROWN read the history of a

FATAL CASE OF VESICAL CALCULI.

The patient was a man of sixty-one, who was born in Palestine, of Turkish parents. Complaining of inability to pass his urine, accompanied with much distress, he applied to Dr. Brown, who found that the penis was of unusually small size, and that the meatus was occluded with some hard substance. He incised the meatus, which was of very narrow calibre, and removed several calculi. After this, he continued gradual dilatation of the urethra until a No. 18 sound could be passed, and at no time during the dilatation was any evidence presented of stone in the bladder.

After this the patient had no further trouble for two years, when he again presented himself, suffering from stoppage of urine. Calculi were again found in the urethra, and every day for a considerable time some were removed. On one occasion, in endeavoring to get into the bladder, which was now quite a difficult matter, Dr. Brown's assistant made a false passage. There was marked cystitis, and the patient gradually sank. After death, the bladder was found to be full of calculi.

The question naturally arose: was this a large stone which had spontaneously ruptured, or were there originally a number of small stones, which formed in the kidney, and received accretions in the bladder? The shape of the calculi seemed to indicate that the former was the correct hypothesis, and this was also rendered the more probable by the complete absence of renal colic during the history of the case. In conclusion, Dr. Brown alluded to instances recorded by various authors, in which there were a large number of calculi, one of them being the case of Chief Justice Marshall, related by Gross, in which Dr. Physick found over one thousand.

The bladder, which had not as yet been opened, was now presented by DR. J. W. S. GOULEY, to whom Dr. Brown had given it for the museum of the New York State Medical Association. He said that it had contracted to some extent since it had been placed in an alcoholic solution, and that, to the touch, it felt like a bag full of coarse gravel. On laying open its cavity in the presence of the members, he found that its walls were somewhat thickened, although not to such an extent as might have been expected. The calculi which it contained reached to the upper fundus. On emptying them out, he found that there had been a spontaneous fracture, not of a single large stone, but of a number of smallish stones, nearly all of which had been too large to be expelled spontaneously. There was, however, no urethro-vesical obstruction, such as would have been caused by an enlarged prostate, and there was, therefore, no reason why some of them should not have been discharged in this way. The mucous membrane was found to be more or less columnar, and in it were a number of little pouches. One of them was large enough to admit the end of the little finger, and at this point there was some ulceration of the membrane.

This, then, Dr. Gouley said, was a case of multiple calculi, and it was one of a very puzzling character. Many explanations had been offered for the spontaneous fragmentation of large stones in the bladder, and there was, indeed, scarcely an authority in this department of surgery who had not brought one forward. But in the present instance not one of them was applicable, and he was at a loss how to account for the condition of affairs met with. Taking up a number of the pieces, he said that he held no less than eleven distinct nuclei in his hand, and that there was not a single entire stone in the mass found in the bladder, which would probably weigh over a quarter of a pound. The case was one of great interest, and he felt sure that even if the diagnosis had been made easily, the result would have been the same. The extraordinary feature of it was the spontaneous rupture of all these stones.

DR. J. R. MACGREGOR related a case occurring in his practice some years ago, which, he said, very appropriately supplemented that of Dr. Brown, and which also illustrated very markedly the fact that there sometimes existed unknown conditions which could not possibly be diagnosed beforehand. The patient referred to was a married lady of sixty-three, who had had no children. She came to him stating that she had had a great deal of pain for a long time in the hypogastric region, and bringing with her a box containing more than three hundred and twenty calculi, which she had voided from time to time.

A vaginal examination revealed the fact that a number of calculi could be felt with the fingers, apparently in the bladder. A further examination was made at her own home, when gradual dilatation of the urethra was accomplished with sounds, and a narrow-bladed pair of forceps introduced into the bladder. Nothing like a stone, however, could be detected, and this attempt gave rise to so much pain and distress, that the patient declined any further interference for the time being. She then went out of town for the summer, but by the time that she returned her suffer-

ings had increased to such an extent that she was willing to submit to any procedure that promised relief. The late Dr. Studley was called in consultation, and, ether having been administered, the urethra was gradually dilated until the finger could be introduced into the bladder. No calculi were found loose in the latter, but plenty of them could be felt, covered, apparently, with some sort of a membrane, and it was concluded that the calculi were encysted. With the finger-nail and a pointed instrument, the supposed membrane was ruptured, and two calculi, each about the size of a grain of corn, were extracted. The others that were felt receded beyond reach when the effort was made to get at them. The discovery was then made that there was also a stone present of very large dimensions, but it was deemed imprudent to attempt anything further on this occasion. The patient had taken ether very badly, so that at one time it was necessary to resort to artificial respiration and hypodermic injections of brandy, and she died in about forty-eight hours.

At the autopsy, there was found in the pelvis an organ resembling a uterus at the fifth month of gestation; and, on section, there was discovered in it one stone of enormous size, together with a large number of small ones. The organ which contained them proved to be the left kidney, which had become displaced, and occupied the ordinary situation of the bladder. It was flattened out like a large sac, and in it were found more than five hundred and twenty calculi, while some additional ones were lost in the abdominal cavity. The large stone, which Dr. MacGregor now presented, was somewhat pear-shaped, and weighed no less than fifty-one ounces. It was six and three-eighths inches in its longitudinal axis, and measured sixteen and five-eighths in its larger circumference, and twelve and one-half inches in its smaller circumference. At each end there was an area where the surface had been polished off by contact with the small stones. The mass had never been sawn through, but was supposed to be composed mainly of uric acid, although the exterior was thoroughly encrusted with earthy phosphates.

Dr. MacGregor then proceeded to give an outline of some of the recorded cases of unusually large stone, commencing with that of Sir Thomas Adams, Alderman and Lord Mayor of London, who died in 1667, at the age of eighty-two. In conclusion, he said that with the exception of the stone in the possession of Dr. Liston, the one now exhibited was the second largest stone on record; and that when its association with a large number of small stones, and its position in the kidney, and the abnormal conditions arising therefrom, were considered, this was certainly to be regarded as a case of the greatest interest.

DR. ALFRED L. CARROLL inquired if there was an evident opening between the kidney and the neck of the bladder. If the stone had a phosphatic coating, he could not see how this could otherwise be accounted for.

DR. MACGREGOR replied that there was no opening and no adhesions, but he thought it probable in a sac so large that the pelvis of the kidney really served as a substitute for the bladder. The extraordinary size of the pelvis of the kidney would account for the phosphatic deposit, because it had acquired new functions. The proper function of the kidneys, however, was but little, if at all impaired.

DR. GOULEY said that the explanation given by MacGregor was hardly necessary, since it was a fact that phosphatic deposits would take place in any part of the urinary apparatus. He had formerly been skeptical in regard to this point, but he had so often observed such deposits in the pelvis of the kidney, that he was fully convinced of their occurrence. In herbiferous animals, moreover, the kind of stone that ordinarily originated in the kidney was the phosphate-of-lime calculus. Dr. Gouley then exhibited a work of John Greenfield, published in 1710, which contained a plate of the stone found in the bladder of Sir Thomas Adams, and also some other ancient books, with plates, on the subject of stone.

DR. IRA B. READ related the history, and presented the specimen from a

CASE OF PERICARDITIS WITH COMPLICATIONS,

the most prominent feature of which was the extensive adhesions between the heart and pericardium, and pericardium and pleuræ, which rendered an exact diagnosis difficult. The patient, an adult male, in March last, had a slight attack of rheumatism, which was confined to one knee. In July, he began to suffer markedly from shortness of breath, and he then recalled that he had felt this to a slight extent at times for about a year. The dyspnœa now increased rapidly. The heart's action was tumultuous, being rapid and weak; but no friction-sound or evidence of effusion in the pericardium could at any time be detected. The temperature continued high. Prof. Edward G. Janeway was called in consultation, and the diagnosis of pericarditis was made. At the autopsy, it was found that the pericardium was closely adherent to the heart; that there had been no chance during life for any movement between the two, the absence of friction-sounds and signs of pericardial effusion being thus readily accounted for. About the 1st of August, seventy ounces of fluid were drawn off from the right pleura, an extensive effusion having occurred there, and this gave the patient much relief temporarily. Later, about one week before death, twenty-eight ounces of fluid were withdrawn from the right pleural cavity. The heart trouble still continued, however, and the patient succumbed before the 1st of September. The question arose: Did this pericarditis have its origin in the slight attack of rheumatism which occurred in March? As far as he was able to judge, it seemed to Dr. Read that it must have had an older history than that.

DR. F. GRAUER described the condition found at the autopsy of a somewhat similar case which he had made recently. Four months before death the patient had an attack of pericarditis, from which he apparently made a good recovery; but about two months later he began to suffer from dyspnœa, and this steadily increased. The autopsy showed that he died from paralysis due to over-distension of the right ventricle. There was also excessive hypertrophy of the left ventricle, due to adhesions.

Dr. Grauer then presented the specimens from a patient of Dr. Janeway's who had died from

PERFORATION OF THE CŒCUM,

following obstruction of the gut. On the afternoon of November 19th the patient complained of colicky pains, and in the evening of the same day he died of collapse. At the autopsy, the cœcum, which was per-

forated by ulceration, was found distended almost like the stomach, the cause of the obstruction being a strong fibrinous band originating from chronic adhesive peritonitis. The muscular coat of the small intestine above the seat of obstruction was very markedly thickened, and the same was also true of the colon. Dr. Grauer thought it very doubtful whether the patient could have been saved if laparotomy had been performed in this case, on account of the condition found at the autopsy.

Dr. Isaac E. Taylor related two cases of intestinal obstruction which had come under his observation.

Recent Literature.

Cyclopædia of Obstetrics and Gynæcology: the Four Volumes on Obstetrics. Being the Treatise by Dr. A. Charpentier, translated under the supervision of, and with notes and additions by Egbert H. Grandin, M.D. New York: William Wood & Co., 1887.

Charpentier's treatise, published in 1882, is too well known, by specialists at least, to require especial notice at this time. The author's aim was to write a work "which would give to the practitioner, student, and midwife a sufficient, although condensed, knowledge of modern researches" in the science and art of obstetrics. While we doubt very much whether the midwife and undergraduate student in this country, will find this work best suited to their use, physicians will value it not only as the best modern exposition of French obstetrics, but as a fair critique of German and English opinion from a French point of view.

In preparing this edition for American readers, the editor has sought by occasional corrections and additions to express the changes in opinion and practice which have occurred since the publication of the French edition; and he has also interpolated criticisms of French methods in so far as they are not in accord with the best practice in this country.

Volume I is devoted to the anatomy of the internal and external genitals, menstruation and fecundation, normal pregnancy and labor. The editor's notes in this volume are necessarily few, from the nature of the subjects treated, the most valuable and important being those on the management of the third stage of labor and on the use of the abdominal binder. While substantially agreeing with the editor in his views as to the use of ergot after the uterus is empty, we would raise the query whether the use of ergot for ten days after delivery does not sometimes markedly diminish the secretion of milk: this has seemed to us to be the result in some cases, and we believe, therefore, that when ergot is thus used, this possibility should be kept in mind.

Volume II is devoted entirely to the pathology of pregnancy. The editor's chief notes are in the chapters on miscarriage and extra-uterine pregnancy: they are in entire accord with advanced opinion in this country, and add materially to the value of the book.

Volume III treats of the pathology of labor, and there is also a chapter on the uses of ergot. It is in the subject-matter of this volume that we should expect most conflict of opinion between French and American authorities. The treatment of ineffective pains in the first stage, the question of version *versus* high-forceps in the minor degrees of pelvic contraction, the treatment of perineal lacerations, of post-partum hæmorrhage, and of placenta prævia have all received adequate attention from the editor, and the views of the best authorities in this country have been fairly stated.

Volume IV the author devotes to the obstetric operations and the pathology of the puerperium: although these subjects are very well treated, there is ample opportunity for revision, of which the editor has taken full advantage. The editorial work in connection with the subject of puerperal fever gives us great satisfaction.

In a work of such importance it is disappointing that the illustrations should be so poorly executed; they are all coarsely done and in many instances the designating letters, numbers, and leading lines are so indistinct as to make the cut practically useless. We trust this defect will be remedied in a subsequent edition.

Pathology and Treatment of Ringworm. By George Thin, M.D. London: J. & A. Churchill. 1887.

This is an excellent monograph upon the subject. The first chapter is devoted to a consideration of the structure and nature of the fungus known as trichophyton tonsurans, and to a description of the various methods of its cultivation in liquid and solid media; a branch of the subject which has received special attention from the author and upon which he is an authority. The rest of the book considers in detail the etiology, pathology, clinical aspect, and the treatment of ringworm in all its varieties. Any one who has much to do with the treatment of ringworm of the scalp gradually finds himself tending towards nihilism in therapeutics, and pessimism in prognosis with regard to it and as the author remarks "when many remedies are recommended in the treatment of a disease it is only too probable that not much confidence can be placed in any of them. Unfortunately, the latter proposition applies to the treatment of ringworm" (of the scalp). An appendix to the treatment of tinea capitis gives the views of three distinguished French dermatologists upon the subject, Vidal, Lailler and Besnier. Vidal gives the average duration of ringworm of the scalp as from ten to fifteen months. Lailler states it to be from twelve to fifteen months, and Besnier says "the duration of tinea tonsurans is always long; from two months to two years." It is well for the practitioner to bear the above statements in mind and not to be led astray by "remarkable results" in the way of treatment which he may see published in the journals, and thus be tempted to fly from one remedy to another in desperate uncertainty. As said before, the monograph is a most excellent one, and well worth the reading.

G. H. T.

— Oil of turpentine is said to be a powerful deodorizer for iodoform. A little rubbed on the hands will completely remove the smell from them. The hands should be afterwards washed in soap and water. In the same manner spoons and any utensil may be freed from the smell of iodoform.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 15, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

IS THERE A CONGENITAL SOUND-DEAFNESS?

AMONG the well-recognized varieties of aphasia due to pathological lesions in the left inferior parietal lobules, the first and second frontal convolutions and the vicinity, are the so-called word-deafness and word-blindness, the latter of which we had something to say in our last and elsewhere in our present issue. The question has been lately raised whether besides these phenomena, resulting from disease, there is a congenital sound-deafness, bearing something of the same relation to ordinary deafness that color-blindness bears to complete lack of sight. The phenomena which lead to such a supposition naturally come more under the cognizance of the teacher than of the physician, and a recent writer in the *London Journal of Education* in an article quoted at some length in *Science*, has discussed the question from the pedagogic point of view, adopting the opinion that there is such a congenital defect. This conclusion he bases upon some curious instances observed in children of the lack of power to distinguish between sounds, vocal and consonantal, of really marked difference, and upon the inability of certain children to spell even phonetically words read to them for the first time. For example, this writer found that one boy, in writing poetry which he had committed to memory, spelled "very" "voght." The boy was very slow in learning to read. Experiment showed that though he was not deaf he could distinguish no difference between the words "very," "perry," and "polly." It was, moreover, noticed that when a class of boys read aloud in concert, some of them would give, instead of a printed word, its synonym, although the latter was of totally different sound from the former. Yet, with some apparent inconsistency with his former statement, the writer says that these boys were those in whom the power of hearing was already under suspicion.

A boy of eleven, while a generally poor speller, was noticed in writing from dictation to make mistakes, especially in interchanging l and r. He wrote "sunderelents" for "sundry rents," "compreated" for "complicated," "laserlacions" for "lacerations," etc. He cannot pronounce these letters, and his teacher believes the defect to be in his ears, though he is not at all deaf.

After remarking that on the analogy of color-blindness it might be expected that vowel sounds would be more likely to be confused than consonant sounds, he continued:—

"The confusion caused by explosive consonants is, however, more remarkable than that from vowels; the inexperienced ear which is dull at catching consonants is capable of any distortion of sounds. To illustrate this, an experiment was tried with a class of eleven boys, averaging ten and a half years of age, and all able to read fluently, one or two of them being somewhat extensive readers. Some short ordinary words were selected, which nearly all got right, and then words specially to test the power of hearing, some of which, it was hoped, the subjects of the experiment had never heard before. Here are the variations of five words (the italicized vowels show inter-change in the hard-vowel scale):—

	Different	capable	ultramarine	spectroscope	Epaminondas
1	diffreant	capbul	ultrmean	spucerow	apnonas
2	different		ultramarine	specoreurscope	aparmondas
3	diferent	capeperbul	altrermerine	speckshow	aponedondas
4	diferrent	capperble	altrermerein	speckros-cop	achappynomeen
5	diferant	cameble	oltremer	spkerrope	appanandex
6	drifrent	capable	untummerrein	specteroskop	epameeondeons
7	diffrent	capabybely	ultrican	spesptrocope	eneandass
8	drifent	capebibel	ultrenn	spectuscope	epermondes
9	different	capebale	ultermeriem	specktrocope	apporymondas
10	differant	ackable	ultomarien	spreting	apanenondes
11	differint	caperble	ultrumeree	spatroscope	appongamanges

"The room was a small one, and the words slowly pronounced twice, each word being written immediately after it had been read out. The majority of these boys are unusually intelligent. The worst speller but one recited, soon after his eighth birthday, 'The Battle of the Lake Regillus.'"

"Twenty words in all were read out. Among them were 'yellow,' which all got right; 'instance,' five right, one of the best readers giving 'insentsess;' 'aniline,' of which there appeared these variations, 'haniyne,' 'anileling,' 'anelile,' 'animiene,' 'aleline,' the rest being at any rate phonetically correct."

Such failures as these to catch the sound of new words, or at least to depict that sound orthographically, are interesting, but several causes of error are to be allowed for before setting down the result of such tests as evidence of a true sound-deafness. The first of these is lack of attention of the pupils to just what was said. Leaving out of account actual stupidity, which must be very common among the class of children observed, lack of close, sharp attention to just what is said is an almost universal failure of children, even among such as might be classed, like these eleven boys, as "bright." An unexpected question asked quickly of a child, even if couched in perfectly simple language, usually requires to be repeated before it is grasped, unless the child has a power of attention greater than current educational methods seem to secure.

Again, the fact noted of the substitution, in reading

in concert, of a synonym for the printed word, does not of itself carry any suspicion of sound-blindness. Many persons, perhaps even those most accustomed to the use of letters, do the same thing. An intelligent reader's mind involuntarily keeps ahead of his eyes. He jumps at the meaning of his author, and is able to finish out many sentences irrespective of the author's own words. What, then, more natural than that, having framed a word expressive of the author's meaning, and finding its substantial correctness confirmed by the slightly tardier evidence of his eyes, he lets his synonym go without correction? We probably all notice this in reading aloud, when we turn a page, and occupying that trifling delay by supplying the first word of the following page.

Finally, we cannot help thinking that much of the poor spelling and of the discomfiture of children in the presence of combinations of letters which are novel to them, is to be ascribed to the fallaceous modern "method" of teaching children to read. Our author says of these supposed victims of sound-blindness: "I inferred that they associated the printed letters not with their sound, but with the concrete thing which they represented, much as if they had been a picture." Now, just this is what is aimed at by the present popular mode of teaching. A child is taught to recognize groups of letters, that is words, as a whole, without reference to their individual constituents. "He reads before he knows his letters," is the boast of the teacher. The spelling-book no longer occupies its once dignified station in the school-room. This meets with the approbation of the scholars, and perhaps it may be defended on the ground that other studies are really of more intrinsic importance. But when, as a natural result, the scholar falters before some new word, with the sound and meaning of which he is perhaps already familiar, but with which he has no means of associating the characters before him, it is not fair to set his failure all down to the credit of sound-blindness.

Other observations, eliminating some of the errors noted above, will be welcomed as casting light upon the question whether there is a congenital sound-deafness. Meantime, we are more inclined to look for the acoustic analogies of color-blindness in the not rare lack of tone-sense, or, as it is popularly called, the "ear for music."

WORD-DEAFNESS.

Word-deafness is the inability to comprehend the signification of spoken language; or, in other words, it may be defined as the amnesia of audible signs.

First accurately described by Wernicke,[1] in 1874, and named by Kussmaul *Word-deafness*, this form of sensorial aphasia was distinguished from mental alienation, on the one hand, and from ordinary deafness on the other, by Baillarger, as appears from the following citation from his academical discourse,[2] delivered in 1865:

"There is at this moment in my service a woman who cannot give the names of any of the more common objects around her; she cannot even tell you her own name. When any object is presented to her she makes a sign that she recognizes it, and endeavors to recall its name, but is unable. She is conscious of her condition, and is greatly distressed thereby.

"At the same time, this woman utters hosts of incoherent words, accompanying them by various expressive gestures, which prove that behind this incoherence there are definite ideas which she would fain express. The perversion of language was at one time so great in this patient that we believed her to be deaf and insane. The question of deafness was easily decided, but not so with the question of mental alienation. The lunatic, as has been said, is an unfortunate being who is unconscious of his own state; now this essential characteristic is wanting in our patient, who seems, in fact, well to appreciate her condition, and is, moreover, entirely devoid of all irrational acts."

The symptoms of word-deafness are well depicted in the report of a typical case by M. Girandeau, in the *Revue de Médicine* for 1882.[3] The patient, B. M., was a female, aged forty-six years; entered St. Antoine Hospital in the service of Hayem. Etiological antecedents, very obscure; no specific affection. For three months patient had suffered continuous headache, the pain being located in both sides of the head. For a month prior to admission, and subsequently, was suffering from the aphasic affection in question. When asked a question, as "What is your name?" her invariable reply was: "I do not understand." Occasionally, however, on several repetitions of the question, the idea seemed to be awakened in her, and she replied correctly. The organ of hearing was found to be intact; the ticking of a watch and other low sounds could be distinctly heard. This patient could read written or printed language readily, and could answer written questions with facility, replying either by word or by writing. The special senses all seemed to be intact and motility was good on both sides. This case proved fatal, and the autopsy disclosed a sarcoma occupying the posterior portion of the two first tempero-sphenoidal convolutions on the left side.

The subject of word-deafness is, to use the expression of Kussmaul, like a person in the midst of a people speaking a foreign language. A patient of Seguin's having this affection used to say: "If I go to a lecture or hear a sermon, I hear the speaker, but what he says is all Greek to me." This patient could, however, go to a concert and understand musical notes.[4] Persons afflicted with this form of aphasia, when a question is addressed to them, manifest an air of surprise, or seem more or less stupid, and their

[4] Pepper's Syst. Am. Med., Vol. v. p. 31.

answers have no relation to the question asked. The vocabulary of some of these patients is limited to a very few words, as in a remarkable case reported by Rosenthal.[5]

With regard to the usual course of this affection, verbal-deafness, according to Wernicke, is of all forms of aphasia that which is the most likely to be recovered from. His first case is an instance of the kind, so also are those of Schmidt and Bernhardt. L. J., Charcot's patient, whose history is given in Bernard's work, was for two years able to utter only the words *yes* and *no*, and all comprehension of spoken language was lost; this patient had right hemiplegia with contracture; the recovery of speech was eventually quite complete.

With regard to the cortical lesion with which this form of sensorial aphasia is in constant dependence, the present state of our knowledge is well summed up by Keraval, in a note to Nothnagel's *Topische Diagnostik*, which he has translated: "This affection is clearly in relation with one of the left temporal gyri. It is certain that in typical cases accompanied by an autopsy there has always been noted, alone, or accompanied by other lesions, softening or other alteration of the two first tempero-sphenoidal convolutions on the left side, or of the upper-half of the first tempero-sphenoidal in its posterior part. In eliminating all cases where word-blindness is a complication, and the lesions which pertain to the latter, and in taking account only of the lesions met with in word-deafness *pure*, we are impelled to the conclusion that some morbid alteration of the *left temporal lobe*, and in particular, of its *supero-posterior extremity*, is a constant correlative of the form of aphasia in question."

The above view is, in words, almost identical with that advocated by Nothnagel. The cases on which it is founded are some twenty in number, and no facts have as yet been brought to light which seriously invalidate the conclusion.

THE CANCER BACILLUS.

WE have been expecting, these many years, the announcement of the discovery of the cancer bacillus. That the causal agent of this dire disease has not hitherto been found, is not owing to any lack of research and investigation. What ambitious bacteriologist, but has hoped at some time to startle the world with the discovery? By some deft process of staining, this (microscopic) monster of pathological depravity, which hitherto, like a true imp of darkness, has concealed itself from human vision, was to be branded and exposed to the scientific gaze. By suitable devices it was to be fished out of its haunts, and made to demonstrate *in vitro* its secret methods of morbigenous proliferation. The fiftieth generation of its descendants, well nourished in gelatinous media, was to be made, by suitable inoculation procedures, to unfold all the phenomena of carcinomatous genesis. All this, the ardent microbiologist has hoped would sometime be his fortunate experience, and how he has toiled at the microscope till his vision was dimmed! But sections of morbid growths, and glass slides daubed with cancer juice, however stained, have hitherto revealed no bacteria that were distinctively new, or *sui generis*, and the diligent worker has eventually given up in despair the hunt for the hypothetical microbe.

But M. Scheurlen, of Berlin, claims to have been more successful, and the last number of the *Semaine Médicale* contains a brief communication in which he claims to have actually found the bacillus of cancer, a claim previously set forth in the telegraphic columns of the *New York Herald*, and referred to in our last issue. In brief, he takes from the interior of a mammary carcinoma that has been antiseptically treated, a drop of cancer juice. This, under the microscope, gives masses of amorphous spores. Inoculated in the sterilized liquid of a pleuritic effusion, which after being heated to 80° or 90° C., is allowed to coagulate, it gives rise, after three days, to a colorless pellicle, which soon becomes corrugated, and turns yellowish-brown.

On examining this pellicle under the microscope with a No. 2 eye piece and a one-twelfth Seibert immersion lens, Scheurlen finds abundant peculiar bacilli and oval spores, glittering, greenish, with motions (active or molecular) of rotation. The method of staining is almost identical with that by which Koch's tubercle bacilli are demonstrated.

Scheurlen has now, since the first of October, been experimenting with the results of his cultures. With the product of the culture of cancer juice on agar-agar, he inoculated six dogs, choosing for this purpose bitches, and injecting the culture liquid into the mammary gland. Four of these animals are still living, two have been slaughtered, the one on the thirty-fifth, the other on the twenty-eighth day after the injection. In the tissue of each mammary gland was found a hard tumor, the size of a filbert. The microscopic examination of this tumor disclosed large granular cells, some of which were certainly epithelial. By the side of these, there were cells undergoing fatty degeneration. Scheurlen does not doubt that this was a case of chronic inflammation with cancerous degeneration. The presence of the cancer bacillus in these tumors was demonstrated by the microscope, and by cultures which were made.

The four living dogs are shortly to be killed and the microscopic and other results reported.

The above account is of interest as indicating the possibilities of experimental investigation in this most obscure department of pathology. Whether or not M. Scheurlen has really discovered anything, or whether he has been pursuing a scientific will-o'-the-wisp, future researches must determine.

FAITH-HEALING EXTRAORDINARY.

A MEETING of Faith-healers was held last week in Chicago, at which, according to the Press reports, an audience of two thousand person were treated to his-

[5] Centralblatt für Nervenheilkunde, 1884, No. 1.

tories more wonderful than those usually narrated on such occasions. The peculiarity of these testimonies was their reference to phenomena, usually supposed to be limited to crustaceans and other lower orders of life, such as the reproduction of lost members. For instance, a Swede declared that having lost his sight by an accident, not only had a diseased eye, through faith, become sound, but that in less than a week a new eye grew in the place of the one that had been removed. A clergyman stated that he had been born with hip disease, and that one foot (*sic*) being three inches longer than the other, he was cured in a moment, and suddenly found his old, short member as long as the other. Beside such statements as these, the usual class of reports, relating to the domain of internal medicine are likely to lose their interest for the brethren and sisters. The latter can probably be depended upon, however, in future meetings not to be left behind in the marvellousness of their experiences.

MEDICAL NOTES.

—A correspondent writes to the *Atlanta Medical and Surgical Journal* of an unusual case, that of a primipara aged twenty-one years. Nothing unusual occurred until the head was pressed against the coccyx, which did not yield. He applied the forceps and delivered her without any trouble and without any laceration of perineum. Immediately after delivery she suffered intense pain in the region of the coccyx, for which she was given an opiate and the bone examined. Some displacement was found, which he corrected, supposing it to be fractured. The opiate soon relieved the pain; she did not suffer any more until the ninth day, except some tenderness in the region. She had some slight pain on that day. On the tenth she passed a bone per anum, stating that she thought she had passed a joint of her backbone. Upon examination the doctor found it to be the lower segment of the coccyx. She has had no trouble since.

— The *London News* published the other day an interesting list of noted men now living, and what is more, now working at an advanced age. The paragraph was suggested by the occurrence of M. de Lesseps' eighty-second birthday. He can look around him and see but very few men of anything like equal eminence who are as old as he, says the *News*, referring to the event. The German Emperor is 90; Dr. Dollinger is 88; Moltke and Bancroft, the historians, are each 87; Kossuth is 85, and Prof. Owens is 83; but it is not easy to extend the list. Yet it is astonishing to note the large number of living great men, who have passed the ordinary limit of human life. Of sovereigns, the Pope is 77, and King William of the Netherlands is well on his 71st year. Of statesmen, Mr. Gladstone will be 79 next month, Mr. Bright is 76, Prince Bismarck is 72, M. Jules Grévy is 74, M. Leon Say and M. Leroyer are each 71; Lord Selborne is 75, Sir Rutherford Alcock is 78, Lord Sherbrooke is 76, and Lord Granville is 72. Of generals, MacMahon is 79, Lebœuf is 78, and Bazaine and Cialdini are each 76. Of poets, Lord Tennyson is 78, Mr. Browning is 75, and Dr. Oliver Wendell Holmes is 78. Of musicians, M. Verdi is 73. Of engineers, Lord Armstrong is 77 and Sir John Hawkshaw is 76. Of painters, Meissonier is 72, and finally, of showmen, Barnum is 77. Perhaps, however, M. Chevreul, who is fairly started upon his 102d year, ought not to be omitted. In any case the catalogue is far from being a complete one. As it stands, it is sufficiently remarkable. We have mentioned the names of thirty-three persons, the average age of each being over 78. It may be doubted whether in the history of the world thirty-two men of as considerable celebrity and of as great average length of life have ever before been alive at one time."

—A bill has been drafted by a committee of English architects and civil engineers, for the State registration and control of these professions, which at present are open, as is medicine in Massachusetts, to any one who choses to invest in a sign and expose it before the public. That great harm is done by incompetent architects through plumbing, unscientific in design and slightly supervised in construction, is evident. But a correspondent of the *Philadelphia Medical Times* cites a case where similar blundering was committed by a man who stood high as an architect in London. A small country house was built from the designs and under the superintendence of one of the leading architects in London. It was most conveniently planned, soundly built, and the elevation is very picturesque. The drains, however, were very badly arranged, and when examined recently were found to have been so carelessly finished that not one was in proper working order. Evidently an ignorant or dishonest builder had been allowed to make the connections between the house-pipes and the drains in any way that pleased his conscienceless soul, the architect not caring to take the trouble to ascertain whether the beautiful house he had built would not be rendered almost uninhabitable by imperfect drainage. Yet this very gentleman, were such a council to be established as is proposed, for controlling the practice of that profession, would very probably be one of the first persons nominated or elected to it. *Quis custodiet custodes?* There is reason to believe that American architects are sometimes open to similar criticism, at least, in their supervision of work, which they may have planned correctly but in which tricky builders contrive to blind their eyes.

BOSTON.

— An important case under the law regulating the sale of poisons was heard before Judge Forsaith at the municipal criminal court, last week. A druggist's clerk was charged with selling poison contrary to the provisions of Chapter 38 of the laws of 1887. It was the first case under the new statute that has come into court. The facts were these:

J. A. Nicholson committed suicide in Boston on

November 19th. He had made one attempt previously. On the nineteenth he bought at Cole's drug-store on Tremont street, three grains of strychnine which he took on his return home. He died a few hours later. Before he died he told his mother where he got the poison. The label did not show this. Medical-Examiner F. W. Draper, with an officer, visited Cole's drug-store. The defendant clerk admitted the sale of poison, of which he made no record. He said he thought it was to kill a sick dog. In court he admitted the sale of the poison. It was urged in his behalf that he was a foreigner, ignorant of the laws of the State, and that his employer had said that there was no need of making a record of sales. It was shown that the defendant had previously sold some poison to kill a sick dog, as he alleged, but the first record of the sale of poison was three days later than the 19th.

Judge Forsaith held that the case rested on the admission of the young man that he had sold poison without making a record. He was fined $30 without costs, and an appeal was taken by his counsel, to the superior court but subsequently the fine was paid and the appeal withdrawn.

NEW YORK.

— The annual meeting of the supervisors of the New York Orthopædic Dispensary and Hospital was held December 8th, and the annual report showed that in the last ten years the institution had made all its beds free. There are now twenty-five beds instead of fifteen (only two of which were free), as formerly. The report of Dr. Newton M. Shaffer, surgeon-in-chief, showed that during the past year the number of new patients was 731, and of continued patients, 986. The cases of diseases included 349 of Pott's disease, 104 of lateral curvature of the spine, 127 of club-foot, 79 of knock-knee, 118 of bow-leg, and 98 of infantile paralysis. The deaths were twenty-four in number, and 413 patients were discharged permanently benefited. 10,079 visits were made at the dispensary; 970 at residences. At the meeting, addresses were also made by Bishop Henry C. Potter and Dr. F. LeRoy Satterlee.

— The Methodist Episcopal Hospital on Seventh Avenue, Brooklyn, the funds for which have been mainly provided by Mr. George I. Seney, has been partially completed and was formally dedicated on the 13th of December.

Miscellany.

CASES OF POISONING FROM TYROTOXICON.

DR. VICTOR C. VAUGHAN, director of the hygienic laboratory in the University of Michigan reports in the *Medical News*, December 3d, four cases of poisoning from this agent, with three fatal results. The cases occurred in a family of four, of whom the mother, son (aged eighteen), and daughter (aged sixteen), died; the father alone recovering. The symptoms were those of irritant poisoning. The deaths occurred from the fourth to the sixth day of illness. The temperatures were subnormal, in some cases as low as 94. All complained of a burning constriction in the throat, and difficulty in swallowing, and all, as long as they were conscious, frequently called for ice. In all the pulse was rapid and feeble, and death seemed to result from failure of the heart. Those who died voided urine involuntarily. There was a coarse rash resembling scarlatina. The pupils were dilated.

Dr. Vaughan tested the vomitus for mineral poisons negatively. The symptoms did not point to any vegetable drug, unless possibly belladonna; but this was excluded by further investigation.

A post-mortem examination was made in the case of the daughter with negative results pathologically. The contents of the stomach and the liver were analyzed by an expert for mineral and vegetable poisons, without finding any. A cold-water extract of the stomach gave after suitable treatment, the tests for tyrotoxicon, and a portion of it was administered to a kitten about two months old. Within half-an-hour after the administration the kitten began to retch, and soon it vomited. Within the next three hours it was noticed to vomit as many as five times. The breathing became rapid and labored. The animal sat with his head down, and seemed greatly prostrated. The pupils were examined, but could not be said to be dilated. There was no purging. The retching and heavy breathing, with evidences of prostration, continued more or less marked for two days, after which the animal slowly improved.

The source of the poisoning was found after negative examinations of the drinking water and other presumptive ingesta, to have been the milk used, which was kept in a buttery. The house, while kept very tidy so far as washing of floors, etc., was concerned, was very old, and had had a reputation of being unhealthy, there having been much sickness and several deaths among previous occupants. It had no cellar under any part. From the front, at least, the surface sloped toward the house, and the rain-water ran under it. In the floor of one room a trap-door had been placed, and directly under this a small excavation had been made for the purpose of collecting the rain-water when it accumulated under the house. Although this pit was dry at the time of the examination, its sides and bottom were marked with cray-fish holes, showing that water had stood in it. The floor was laid of unjointed boards, and every time it was swept much of the filth fell through the cracks, and every time that the tidy housewife scoured and mopped the floor, the water, carrying with it the filth, ran through the crevices, and thus the conditions most favorable for putrefactive changes were brought into existence, and maintained.

One corner of one of the rooms had been transformed into a small room, or buttery, as it was called, and in this, on shelves, the food was kept. On account of the more frequent scouring demanded by that part of the floor enclosed in this buttery, the boards had rotted away, and a second layer of boards had been placed over the original floor. Between these two floors was found a great mass of moist, decomposing matter, the accumulations of years, which the broom could not reach. When this floor was taken up a peculiar, nauseating odor was observable, and was sufficient to produce nausea and vomiting in one of the persons engaged in the examination. The milk

used was kept in this buttery and the farmer had noticed it often had an unpleasant taste. It was found to contain tyrotoxicon and a kitten was poisoned by drinking it.

Correspondence.

"THE DOCTOR'S WIFE."

CRANBERRY MEADOWS, December 14, 1887.

MR. EDITOR,— My neighbor Cœlebs (*Medical and Surgical Journal*, Dec. 8th), evidently thinks my success entirely due to the fact that I have married. Now, without for a moment wishing to detract from the credit due my wife, I would like to call your attention to a point which he might easily have scored if he had chosen to exert himself a little: *He has never called on the widow of the late lamented Gamboge.*

When I settled here in Cranberry Meadows my first step was taken in the direction of the old lady's front steps. When we met, I expressed my deep sympathy for her in her bereavement — such a thoroughly estimable man (I had never heard his name mentioned until the previous week, when I chanced to learn of the opening) — such a shining light lost to the profession (here I referred tenderly to the only thing old Gamboge ever published, which I had read up in the *Boston M. and S.* the day I took the train to come here, entitled "A Severe Case of Bleeding Piles in a Youth of Sixteen successfully treated with a Decoction of Hemlock Bark," and dated low down in the forties); such a loss to the settlement (where they tell fearful stories of the doses he used to give). In short, I did the proper and becoming thing *under the circumstances*, — asked her for her advice regarding the size and lettering of my to-be shingle, and wound up by showing a degree of youthful diffidence and confusion at the idea of having dared to aspire to fill old G.'s professional Oxford ties, which quite fetched her. From that day she has been my firm friend. It was she who made up the match between Mrs. B. and myself; and the result shows that a doctor's widow (if past fifty) is a good judge of what a young M.D.'s wife should be. She has presented me with her late husband's medical library, which includes some really valuable notes from Nathan Smith's lectures on "Theory and Practice of Physic," taken at Bowdoin in 1827. I have also been made the recipient of his surgical instruments, which include the first and only speculum ever seen in these parts before Cœlebs and I arrived — a formidable-looking weapon of great size and weight, which old Gamboge used to pass through a hole cut in a sheet, with which the victim was completely covered, in the presence of such of the older lady residents of the Meadows as were renowned for their keen sense of propriety.

Just one word more. Cœlebs smokes, and, I am told, occasionally "takes something" in his office; whereas I never touch a weed, unless I chance to get a whiff or two behind the barn (tobacco is very unpleasant to Mrs. B.); and as for stimulants, I haven't tasted a cocktail since I slipped into the Brunswick during the last session of the annual meeting of the M. M. S.

To be respected one must respect himself.

Yours truly,

BENEDICK, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 3, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,294: under five years of age 706; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 403, acute lung diseases 340, consumption 315, diphtheria and croup, 202, scarlet fever 45, typhoid fever 49, diarrhœal diseases 42, malarial fever 25, measles 12, whooping-cough 12, erysipelas eight, puerperal fever four, cerebro-spinal meningitis three. From diarrhœal diseases, New York 13, New Orleans 11, Philadelphia, Portland and Fall River three each, Brooklyn, Boston and Charleston two each, District of Columbia, Pittsburg and Taunton one each. From malarial fever, New York nine, Brooklyn seven, New Orleans five, Baltimore three, Philadelphia one. From measles, Baltimore six, New York five, Pittsburgh one. From whooping-cough, New York and Baltimore three each, Philadelphia and Boston two each, Brooklyn and Milwaukee one each. From erysipelas, New York, Baltimore and Fall River two each, Brooklyn and Milwaukee one each. From puerperal fever, New Orleans two, New York and Boston one each. From cerebro-spinal meningitis, Fall River two, Milwaukee one. From small-pox, New York one.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending November 19th, the death-rate was 21.1. Deaths reported 3,747: infants under one year of age 883; acute diseases of the respiratory organs (London) 461, scarlet fever 85, measles 84, whooping-cough 80, fever 61, diphtheria 38, diarrhœa 31, small-pox (Sheffield 25.

The death-rates ranged from 13.5 in Hull to 30.4. Birmingham 18.7; Bradford 20.9; Huddersfield 24.9; Leeds 26.9; Leicester 15.3; Liverpool 22.8; London 20.3; Manchester 28.1; Nottingham 21.6; Sheffield 22.6.

In Edinburgh 20.6; Glasgow 24.0; Dublin 34.6.

The meteorological record for the week ending December 3, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Dec. 3, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 3, 1887, TO DECEMBER 9, 1887.

HOFF, JNO. VAN R., captain and assistant surgeon. Granted leave of absence for one month, to take effect on or about the 12th proximo. S. O. 128, Department of the Missouri, November 30, 1887.

MUNDAY, BENJAMIN, captain and assistant surgeon. Granted leave of absence for one month, to take effect about December 15, 1887. S. O. 280, A. G. O., December 2, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE FOUR WEEKS ENDING DECEMBER 12, 1887.

WYMAN, WALTER, surgeon. Granted leave of absence for thirty days, November 29, 1887.

WILLIAMS, L. L., assistant surgeon. Granted leave of absence for twenty-one days, November 18, 1887.

KINYOUN, J. J., assistant surgeon. Leave of absence extended seven days, November 29, 1887.

WOODWARD, R. M., assistant surgeon. Granted leave of absence for seventeen days, December 5, 1887.

GASSAWAY, J. M., surgeon. When relieved to proceed to Cairo, Illinois, and assume charge of the service, December 9, 1887.

IRWIN, FAIRFAX, surgeon. Promoted and appointed surgeon from date of oath, December 10, 1887. December 8, 1887. To proceed to Pittsburgh, Pa., Wheeling, W. Va., Gallipolis, Ohio, Evansville, Ind., Cairo, Ill., Little Rock, Ark., Shreveport, La., New Orleans, La., Rome, Ga., Chattanooga and Nashville, Tenn., as inspector, November 12, 1887.

GUITERAS, JOHN, passed assistant surgeon. When relieved, to proceed to Charleston, S. C., and assume charge of the service, December 12, 1887.

BANKS, C. E., passed assistant surgeon. To proceed to Portland, Maine, and assume charge of the service, December 9, 1887.

CARMICHAEL, D. A., passed assistant surgeon. When relieved, to proceed to Washington, D. C., for temporary duty in the office of the Supervising Surgeon General, December 9, 1887.

BEVAN, A. D., passed assistant surgeon. Granted leave of absence for twenty days, December 7, 1887.

GLENNAN, A. H., passed assistant surgeon. To proceed to Key West, Fla., and assume charge of the service, December 12, 1887.

DEATHS.

Died in Lawrence, Mass., December 10, 1887, David Dana, M.D., M.M.S.S., aged sixty-four years.

Died in Boston, December 9, 1887, Charles Harrison Spring, M.D., M.M.S.S., aged fifty-five years.

OBITUARY. DAVID DANA, M.D.

Dr. David Dana, whose death occurred suddenly on December 10th, graduated from the Harvard Medical School in 1847, went to Lawrence, Mass., in 1848, and had successfully practised his profession there ever since, with the exception of the time when he was serving as Surgeon in the First Massachusetts Heavy Artillery, during the War of the Rebellion. Dr. Dana leaves a widow and two daughters.

ON SO-CALLED SURGICAL SCARLET FEVER.

This is the name given by many to any eruption resembling scarlet fever which comes on after a wound or operation, whether it begins at the injured spot or at a distance. Hoffa has analyzed a number of such cases to be found in various publications, and reduces them to four categories. The first three are not true scarlatina, but (1), a simple congestive vasomotor erythema, depending on a vasomotor reflex; (2), toxic erythema, caused by the absorption of secretion from wounds or other fibrinous ferments, or it may be brought on by the use of chloroform, carbolic acid or corrosive sublimate; (3), septic erythema, sometimes very hard to diagnose from true scarlatina — after the rash fades there is occasionally desquamation; (4), a real scarlatina, arising in the usual way from infection. To deserve the name of surgical scarlatina, such cases must have become infected after the infliction of the wound or operation, and the exanthem must have commenced at the wound. Nine cases are selected from the literature of the subject. Hoffa is of opinion that a wound predisposes to scarlatina, as it presents a larger surface for the micro-organisms of scarlatina to attach themselves to, and in this way he explains the shortness of the period of incubation which has often been noticed. Volkmann's *Sammlung*, No. 292, *Edinburgh Medical Journal*, December, 1887.

BOOKS AND PAMPHLETS RECEIVED.

The Confidence of the Public in Non-Professional Prescriptions. By W. S. Leonard, M.D., of Hinsdale. 1887.

Lecture.

THE BONES OF THE LEG CONSIDERED AS ONE APPARATUS.[1]

BY THOMAS DWIGHT, M.D.
Parkman Professor of Anatomy at Harvard University.

Now that we have studied the tibia and fibula in the usual way you are no doubt prepared to admit that the fibula is a most difficult and confusing bone. Indeed, I consider it the hardest in the body, but I wish to show you that the trouble comes from studying it alone instead of in its natural connections. In works on anatomy you find after the description of the bones of the spine, the skull, the thorax and the pelvis respectively, chapters on the spine, the skull etc., as a whole, but this view of the tibia and fibula is not given. I invite your attention, therefore, to a chapter which anatomists have apparently forgotten to write. You will find, I hope, that your ideas of the bones of the leg will be simplified, and that the fibula in particular will have lost half its terrors. Unlike the radius and the ulna, the bones of the leg are always in very nearly the same relative position. They are parts of one apparatus for supporting the weight of the body, forming the socket of the ankle-joint and giving attachment to muscles. The weight-bearing is done almost wholly by the tibia. Both bones have a share in forming the ankle-joint and in certain changes of position of the foot there is some slight motion between them. When the foot is extended,[2] that is, bent upwards towards the shin, the broadest part of the articular surface of the astragalus is brought between the malleoli, and the fibula gives a little. If the socket were wide enough to admit the broadest part of the astragalus without this giving, the latter bone would in most positions be without adequate lateral support. Still the amount of motion is very slight indeed. Very powerful muscles arise from the bones of the leg and the apparatus is broadened at the upper part to give them more room in a way consistent with the least possible increase of weight and the greatest elasticity. If this expansion were of bone there would be a very unnecessary increase of weight, as all that is needed besides the tibia, which is in the line of pressure, is a smaller bar at some distance from it and a membrane between them from which muscle can arise as well as from bone. The fibula is very elastic, and is undoubtedly subjected to much strain from muscular action, especially in sudden efforts, and it is of great advantage that it should be attached to the tibia by a joint to break the shock rather than be of the same piece. If it were not so arranged, fractures of the fibula alone would be much more frequent than they are. Moreover, it is possible to conceive that if the bones were continuous at their ends, the place of the membrane might have been taken by bone so thin as to add very little to the weight, but it is clear that the elasticity of the structure would have been lost or at least much lessened.

When the bones are together the breadth of the upper half of the structure, its narrowing to about the junction of the lower and middle thirds, and the subsequent moderate expansion for the ankle are all very evident. Professor Humphry has pointed out the advantage of the narrowing to reduce the weight near the end of the limb that it may be swung the more easily, and also the need of a certain enlargement of the bones lower down to form the socket for the ankle. The amount of the narrowing varies considerably. It is very much less than usual in the bones from which Figures 4, 5 and 6 are taken. The junction of the middle and lower thirds is well known to be a weak point in the leg and various explanations of the fact have been given. It seems sufficient to say that at this point not only the circumference of the chief bone is at its smallest, but that the girth of the whole bony framework of the leg is smallest too. It is, moreover, as has been pointed out, the place at which the upper prismatic part of the tibia joins the lower cylindrical one.

By the study of these bones on a ligamentous preparation, we get at once a correct idea of another very important feature, namely, the want of parallelism between the transverse axes of the knee and ankle, or in other words the twisting of the bones of the leg by which the foot is turned outwards. If the bones lie on a table, the upper end rests on the internal tuberosity of the tibia and on the head of the fibula, except in some cases, when the latter bone bends so much backwards that a part of the shaft instead of the head is the point of support. In either case the anterior border of the top of the tibia is very nearly horizontal, the shortness of the outer tuberosity being made up for by the backward projection of the fibula. Turning to the lower end we see that it rests either on the outer malleolus or on the outer border of the tibia and that the inner malleolus is in the air. The transverse axis of the joint runs outward and downward. The variation of the degree of torsion is considerable. Mikulicz measured it on one hundred and twenty tibiæ and found that the angle formed by the axis of the knee with that of the ankle ranged from 0° to 48°. The latter was, however, a very extreme case, and but very few approached it. In about two-thirds of the cases it ranged from 5° to 20°. This, to be sure, is easily seen on the tibia alone, but it is much more striking when the bones are united. Another idea which we gain from studying the bones lying on the table in this position, is that the general course of the fibula is not far from a straight one, while the inner posterior border of the tibia describes a great curve from the table. I shall return to this point when we come to the tibia in the living.

Let us now begin the description of the two bones as one piece. You will understand that it is not my intention to repeat the description of points that have been sufficiently dwelt on in the usual account of the bones, but to give you the outlines of the composite framework. I therefore say nothing of the internal structure of the bones and make no effort to give a complete list of the muscular attachments.

We find an upper and a lower end bounding the middle portion. The upper end is the same as that of the tibia plus the head of the fibula, which is situated far back on the outer aspect, and which is below the knee-joint. I have no occasion, therefore, to repeat the description of the upper end of the specimen. The lower end forms the socket for the ankle. The roof of the socket is broader in front than behind, and slightly concave from before backwards. There is a slight antero-posterior elevation in this surface which

[1] A lecture delivered at the Harvard Medical School, November 14, 1887, rewritten and added to.

[2] There is much confusion in the use of the terms flexion and extension as applied to the foot. It seems to me simplest to consider flexion the result of the action of the flexors and extension that of the extensors.

is more easily recognized by the touch than by sight. I would call your attention to the fact that slight changes in the surface of bones are best studied by the finger. Notice that the inner surfaces of the malleoli incline away from one another as they descend. This slant is greater in the short inner malleolus than in the longer outer one which sometimes forms but little more than a right angle with the lower articular end of the tibia.

When we look at the bones lying on the table it is easy to see that the inner malleolus is anterior to the outer. This is due to the twisting of the bones already referred to, for if we grasp the bones by the middle and consider only their lower ends, this does not appear. The outer malleolus is also decidedly longer than the inner. There is a little fold of synovial membrane which continues the ankle-joint a short distance between the bones above the socket. Just above this they are firmly bound together by the interosseous ligament.

We now come to what we may call the shaft of the structure, which consists of the shafts of the two bones and the interosseous membrane. We recognize three borders and three surfaces.[2]

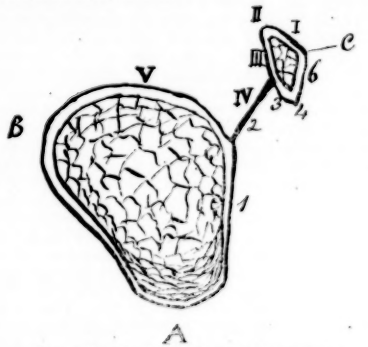

FIG. 1. About two inches below the upper surface.

The *anterior border* A is the crest of the tibia which, beginning at the tubercle, ends at the front of the inner malleolus. Its course is sinuous, the upper part having a slight convexity inwards, the lower, a stronger convexity outwards. In Figure 1, a little below the tubercle, this border is still very thick; at the middle of the leg, it is sharp; and near the ankle, it is not always to be recognized in a cross-section.

The *internal border* B is that of the tibia which begins at the inner tuberosity and ends at the back of the inner malleolus. Of the cross-sections the one at the middle of the leg is the only one which shows it at all clearly.

The *external border* C is the one known as the external border of the fibula (Quain) or the posterior border (Gray)[4] running from the styloid process to the back of the malleolus. The cross-sections show that this is at the outer part of the fibula above and at the posterior below.

[2] The description should be followed on the figures of the cross-sections, as well as on the views of the surface. The former were made from a ligamentous preparation imbedded in plaster so that the proper relations might be preserved. The figures are of the natural size.

[4] Postero-external. Gray. Last edition.

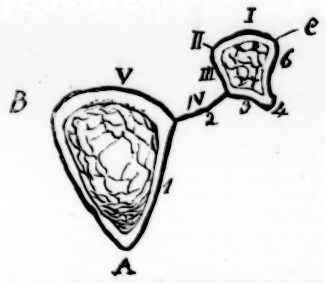

FIG. 2. Near the middle. Though the lines on the surface are well marked, these bones are probably from an old person as the tibia has much less solid bone below the crest than usual.

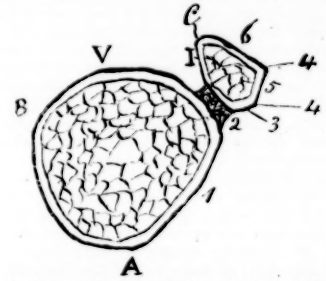

FIG. 3. About one inch above the lower surface of the tibia. The interosseous ligament is seen in place of the membrane.

The *internal surface* is bounded by the anterior, and internal borders A and B. It is seen much fore-shortened in Figures 4 and 6. It is the internal subcutaneous surface of the tibia. Passing the fingers down this surface one perceives that it is slightly convex in the upper part, slightly concave in the lower.

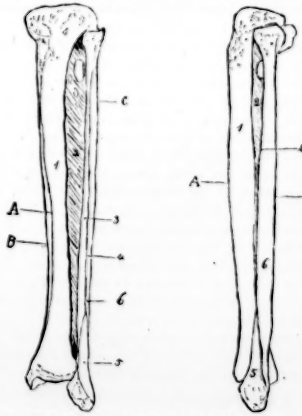

FIG. 4. FIG. 5.

Figure 4 gives the anterior and outer aspect.
Figure 5 gives the outer aspect.

The *antero-external surface* is bounded by the anterior and external borders, A and C. It is much broader above than below, owing to the greater size of the upper part of the tibia and the greater separation of the bones. Its upper portion looks obliquely forwards and outwards but its lower is continued round to the back of the fibula. It presents the following features from within outward (which are marked by corresponding Arabic numerals on the figures): (1) A smooth surface formed by the tibia, the upper two-thirds of which looking outwards give origin to the tibialis anticus. Just below the inner tuberosity of the tibia, the inner part of the origin of the extensor communis is attached to it. The lower third of this surface twists forwards on to the front of the tibia, where it is covered by the extensor tendons. (2) The interosseous membrane forms the floor of a gutter which is shallow and broad above, deep and narrow below. It has one or more openings near its upper angle, of varying size and shape for the passage of vessels and nerves. The three chief extensors all arise in part from the membrane. (3) A narrow portion of the fibula looks inward, forming the outer wall of the gutter and giving partial origin to the common extensor and to that of the great toe. This surface is so perfectly clear when the bones are in place and united by membrane, that it is hard to realize how perplexing it may be on the separated fibula, especially if it be a poorly-marked one. (4) Next comes a ridge, the so-called anterior border of the fibula. It begins near the head of the bone, but at first it is often indistinct. It is very sharp about the middle of the leg. It bifurcates some three inches above the tip of the outer malleolus, one line going to the front, the other to the back of that structure and inclosing (5) a triangular subcutaneous surface looking outward above the outer ankle. (6) The last feature is a surface for the peroneus longus, and peroneus brevis, which beginning at the outer side of the fibula twists to its posterior aspect so that the tendons of these muscles pass behind the malleolus. This surface is strikingly smooth and its spiral course very evident. The two greater peronei are enclosed in a fibrous chamber by fasciæ passing inwards from the deep fascia of the leg to the anterior ridge of the fibula (4) and to the external border of the combined structures (C).

The *posterior surface.* Continuing our course round the back of the leg, we meet from without, inward after passing the external border (C), the following features (marked on the figures with Roman numerals): I, a surface on the fibula looking above, backwards; below, inwards. In its lower quarter it reaches the interosseous membrane. From its upper portion, arises the outer part of the soleus and from its middle portion (more than its middle third) the flexor longus pollicis. II, a ridge called the oblique line of the fibula (Gray),[5] the internal border (Quain) starts from the back and inner aspect of the head of the fibula and twisting inwards and forwards strikes the interosseous membrane somewhat above the lower quarter of the leg. Above this point, another surface, III, looking inward, comes between the ridge and the interosseous membrane, IV. This membrane is at the bottom of a deeper depression than in front. It gives origin to only one muscle, the tibialis posticus, which encroaches also on the bones on either side. It ends below in a sharp angle between the bones just above the interosseous ligament, the surfaces for the attachment of which are not seen when the bones are together. Next comes V, the posterior surface of the tibia. In the upper part of this the oblique line, VI, running downwards and inwards from the head of the fibula, marks off the popliteal surface, and gives origin to a part of the soleus. At about the juncture of the first and second quarters, or rather lower, is the nutrient foramen, the largest in the body, which is directed downwards. If the parts are very vascular, as the result of inflammation, the nutrient artery may give trouble after amputation. The foramen is sometimes very close to the interosseous membrane, sometimes half-an-inch from it. The much smaller canal for the fibula is on one of the posterior surfaces of the bone; most frequently on that marked I. In the forearm the nutrient foramina are found, also on the flexor surface of the bones, but there, they run towards the elbow and here they run from the knee. A much less distinct line is seen running nearly vertically about the middle of the bone, which separates a broader inner portion, from which arises the flexor communis, from a narrower outer one, beside the membrane which gives origin to the inner part of the tibialis posticus.

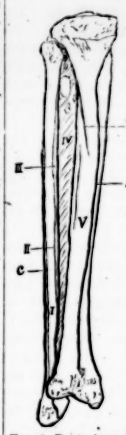

FIG. 6. Posterior and inner aspect.

After this detailed description of the ridges and surfaces of the bones, we return to the study of the twists of the bones and we shall find it a less simple problem than is generally supposed. We saw at the beginning, that the lower part of the skeleton of the limb is twisted outward to allow the foot to assume its characteristic, human position. If we follow the ridges of the fibula, excepting that for the interosseous membrane, we find them pursuing a corresponding course. The surface for the peronei (6), shows this feature strikingly, and the one just beyond it on the posterior aspect (1), hardly less well. Now as the axes of the ankle-joint is determined chiefly by the tibia and as it is undoubtedly turned outward we should naturally expect to find the borders and surfaces of the tibia, turned the same way, but we do not find such to be the case. On the contrary, we find the anterior crest of the tibia twisting downwards and inward to the inner malleolus, and the two surfaces which it separates, to take a similar course. The twist of the posterior surface of the tibia is more difficult to analyze. It would seem as if, at least, the greater number of the surfaces of both bones twist as they descend away from an imaginary line between them.

It is interesting and important to know how much of the bones can be felt during life. The whole of the front and sides of the head of the tibia are easily made out, but it is deeply placed behind and obscured by the hamstrings and the gastrocknemius. The tubercle is very prominent in front, just at the insertion of the ligament of the patella. It is worth knowing that the tubercle is a part of the superior epiphysis of the tibia, which descends further in front than elsewhere. At the sides its line of union coincides with the lower border of the tuberosities. It

[5] Postero-internal. Gray. Last edition.

includes, therefore, the articular surface for the head of the fibula and the upper anterior aspect of the latter, indicates pretty nearly the position of the line. The crest of the tibia is easily traced downwards from the tubercle. The finger that follows it reaches the inner malleolus. In muscular legs the tibialis anticus, projects somewhat beyond it, and this together with the dense fascia covering the extensors that springs from the crest tends to make it a far less prominent feature in the living than one would expect from the skeleton. In athletes, antique-statues and outline-drawings, there is a striking curved line in the leg, which the ignorant might easily mistake for this ridge, but which is caused by the internal border of the tibia. It is well shown in both legs, but especially the left one, of this outline from Flaxman's illustrations of the Iliad, representing one of two giants holding Mars captive. Notice that the line begins high up under the inner tuberosity of the tibia, and ends at the back of the inner ankle, corresponding perfectly to the internal border (B). One of the reasons why some are deceived is that they expect this border to be at the inner side of the leg, in the flesh as it is in the bones, forgetting that the great muscles of the calf, overlap it considerably and fill in a good part of the outline of the leg, even when seen from the front, as in this figure. This border curves forwards as well as outwards, so that this feature can be seen not only from the front but from the side. The subcutaneous internal surface of the tibia can be felt throughout.

FIG. 7. "Otus and Ephialtes held the chain."

The anterior surface of the tibia below the origin of the tibialis anticus is easily felt just above the ankle, though it is obscured by the extensor tendons passing over it. The head of the fibula is to be felt far back on the outer aspect of the leg. Very soon the peronei cover the shaft with a thick pad so that, although the position of the bone can be made out, its outlines are concealed till we get down to the triangular, subcutaneous surface, beginning some three or four inches above the ankle. The greater length, the more posterior position of the outer malleolus as well as the difference in shape from the inner one are easily recognized.

LEAD-POISONING AS A CAUSE OF MUSCULAR INCO-ORDINATION (PSEUDO TABES.)[1]

BY JAMES J. PUTNAM, M.D.

IT is well known that a number of cases have been described within the past few years, usually presenting a greater or less number of the symptoms which we are in the habit of referring to multiple peripheral neuritis, such as objective and subjective sensory disorders of a variety of kinds, and muscular wasting, with diminution of electrical irritability, but characterized above all by inco-ordination in the use of the muscles of the extremities.

The analysis of these cases shows that this inco-ordination may occur without many of the other symptoms of neuritis, just as, in other cases of the disease, the cutaneous sensory disorders may predominate, or even occur alone, or as paralysis may come on, and after lasting for a short time, disappear, without leading to muscular atrophy.

To this group of cases the name of pseudo tabes has been given, and although this name is not really a suitable one for many of the examples reported — those, for example, where the knee-jerk is exaggerated instead of being diminished — yet it is of temporary value as indicating the possibility of confounding cases of this kind with true locomotor ataxia, a mistake which has, in fact, no doubt often been committed.

In such cases as those which form the subject of this paper, there is a true impairment on the part of the patient's ability to co-ordinate their movements accurately, probably due to a loss of the impression coming from their muscles; but another class of cases has also been included under this same name of pseudo tabes, where there is no true inco-ordination, but a disorder of movement due to loss of power on the part of certain groups of muscles. In these cases the gait of the affected patient is of a character that has been likened by Professor Charcot to the movement of a high-stepping horse, because, in consequence of the paralysis or weakness of the extensors of the foot, the toe drops when the leg is lifted, and the knee has consequently to be raised unnaturally high in order to clear the foot from the ground. Furthermore, these patients, on account of their muscular weakness, often walk with an uncertain and somewhat straddling gait.

Of this latter group of cases I do not intend to speak further, although they are doubtless related, pathologically, in many respects, to those where true muscular inco-ordination is present.

All that is absolutely known, so far as I am aware, of the pathology of pseudo tabes of neuritic origin is furnished by the results of three autopsies, two of them reported by Déjérine,[2] and the third by Dreschfeld.[3] In these three cases the disease was presumably of alcoholic origin.

The clinical histories agree in all essential particulars with the clinical pictures already indicated. The central nervous system was found practically unchanged in all, whereas there were marked changes in the peripheral nerves.

The microscopic examinations in the two cases re-

[1] Read before the Boston Society for Medical Development, Nov. 30, 1887.

[3] Brain, 1885, Vol. VIII, p. 433.

ported by Déjérine were especially careful, and showed a degenerative process, mainly confined to the cutaneous nerves, but probably affecting, also, as he thinks, the nerves of the muscular sense.

Besides these cases, the pathological diagnosis of peripheral neuritis as a possible cause of muscular inco-ordination receives much support from what we know of other forms of this disease with which this form is often so intimately associated, and the indirect pathological evidence of this kind is now considerable.

The conditions under which pseudo tabes has been observed are, in the first place, chronic alcoholism; then, in cases of poisoning from arsenic, lead, sulphide and oxide of carbon, diphtheria, and other acute infectious diseases, and perhaps certain vegetable poisons.

Finally, the number of cases reported as traceable to these various causes is so small that in a given instance we cannot always safely assert that the relation between the apparent cause and the symptoms is more than one of coincidence. Furthermore, it is to be remembered that we get the symptoms of the so-called pseudo tabes in a more or less characteristic form, where the sensory tracts are diseased in another part of their course, namely, the posterior columns of the spinal cord. It will be pointed out further on that it is not always easy to say whether we are dealing with a case of inco-ordination from neuritis, which will probably be curable, or with the first stage of certain types of posterior or combined sclerosis of the cord which are likely to prove incurable.

As compared with the other symptoms of multiple neuritis from these different causes, the cases of inco-ordination are rare. Even in chronic alcoholic poisoning, where they are the most common, the whole number reported in literature is very limited.

Of the cases due to arsenic, of which a complete and excellent summary is given by Dr. C. L. Dana in *Brain* of January, 1887, the whole number reported amounts to seven. Two of these cases are described for the first time by Dr. Dana himself, and are of special interest, apart from the clinical picture which they present, from the fact that in one of them the arsenical poisoning was acute, and due to a single dose; while in the other it seemed to be traceable to the continued ingestion of small quantities, taken for medicinal purposes.

The reported cases which we have reason to believe may be of *plumbic origin*, consist only in two, so far as I know, of which I shall take the liberty of giving a brief account.

The first case was reported by Teissier, in the *Gaz. Med. de Lyon*, 1861–1862, and is cited at length in the thesis upon pseudo tabes by Leval-Picquechef, published in 1885. The patient was a young man of twenty-four years, who had worked as a plumber for two years previous to his illness, for which no other cause than lead-poisoning could be assigned. His symptoms, at the time of his first examination, consisted in increasing difficulty in the use of his arms and legs; in progressive impairment of vision and of memory; emaciation, headache and vertigo. He suffered also from sensations of prickling and numbness in his extremities; the sense of touch was found to be diminished in patches, and his speech was somewhat indistinct. On careful examination it was found that the difficulty in the use of his limbs was due, not so much to the loss of muscular strength as to the impairment of his co-ordinating power, and this was so great that he could scarcely stand, or hold a pen. As is usual in cases of this kind, it was extremely difficult for him to keep his limbs in a fixed position. There was a marked lead-line on the gums. After treatment for three months in the hospital, the patient was discharged, much relieved, in all respects, but not entirely well.

The second case is reported by Raymond, and was first published in the important monograph upon chronic lead-poisoning by Renaut (L'Intoxication Saturnine). It is of unusual interest on account of the short time during which the patient was exposed to the poisonous action of lead, and for other reasons. The patient was a man of forty-two years, and began to work in a lead manufactory of Clichy towards the end of January, 1874. He gave up work on the 25th of March, that is after about two months. He had never worked in lead before, and showed no symptoms of lead-poisoning, or other important impairment of health. On the 20th of March, that is five days before he left work, he had an attack of colic, which lasted for nearly two weeks. On the 25th of March he had a convulsion of two hours' duration, and, four or five days later, another convulsion of similar kind. On the 2d of April he became quite suddenly very ataxic, so that he could not carry a cup to his mouth without spilling the greater part of its contents. This ataxia was preceded by a moderate degree of muscular weakness. The next day he had marked formication in his lower extremities, and a few days later could only walk with great difficulty. He had also pains in the head and impairment of sight and of hearing. The inco-ordination of the arms improved as that of the legs came on. There was considerable loss of strength in the arms, but no marked atrophy; and the strength of the two arms was equal, while the inco-ordination was greater on the left side. The loss of hearing was also greater on the left side. Anæsthesia of all kinds was present. In spite of their severity the ataxia symptoms were nearly well after four months of treatment. There was a lead-line on the gums.

To sum up the history of these interesting cases, we have two patients, both exposed to the causes of lead-poisoning, and both showing a lead-line on the gums, and one of them, in addition, characteristic colic and confirmatory cerebral attacks, and both exhibiting a series of symptoms, severe and yet curable, similar to those which we have learned to diagnosticate as pseudo tabes.

I desire to call especial attention to the fact that tenderness of the muscles on pressure is not mentioned as present in either of these cases, and that, for the second, the severest case, at least, it may be certainly assumed to have been absent, because the report says, in speaking of the sensibility, "there are two painful areas in the left leg, in the neighborhood of the articulations of the ankle and the knee; except from these both legs are anæsthetic," etc.

To these two cases I believe that I am able to add three more of my own observation.

The first case is that of a young lady twenty-seven years of age, in good circumstances, and of good previous health. She first consulted me on January 22, 1886, for serious inco-ordination and impairment of muscular strength, affecting, at that time mainly the hands and arms, and impairment of vision, especially

of the left eye. She gave the following interesting history:

The sickness had begun towards the end of the previous August (1885), with aching pains in the elbow of the left arm, and numbness and prickling, with loss of sensibility, along the back of the left forearm and hand. It is especially noteworthy as indicating a peripheral localization of the disease that, at that time, the forefinger and thumb were affected alone, that is, without the other fingers. The same aching pains then attacked the right hip, and similar, but severer, numbness affected the whole of the right leg on the under side, as far as the foot, and including the latter. The affected limbs, at the same time, became more or less weak, but it is interesting to note that, subsequently, this weakness improved rather rapidly. The right hand and the left leg were attacked in the same manner in the following November, that is, three months later. Since then, while the the right hand has been growing worse, the legs have been improving, so that she now feels no numbness there, and can walk with ease.[4]

In the same month (November), she first noticed a sensation as of a broad band drawn tightly around the body below the breasts. This symptom lasted for some weeks, and then passed gradually away, though she is still conscious of it from time to time. Lest it should be thought that the presence of this girdle sensation stamps the case as one of ordinary myelitis, I will here remark that it is occasionally described in cases otherwise characteristic of multiple neuritis, and so diagnosticated by good observers, as, for example, in Obs. III. in the thesis on pseudo tabes, of Leval-Picquechef.[5] The irritation which causes it may occur anywhere, and must occur somewhere, in the course of the sensitive nerve or nerve-roots of the two sides, but it certainly did not, in this case, correspond to the upper level of a transverse myelitis.

At about this same period (Nov., 1885), the vision became blurred, especially, or as she thinks, exclusively, that of the left eye. This blurring came on, she says, quite suddenly, but has steadily increased, so that she has given up trying to read. At first it seemed to her as if there were something in front of the eye which she tried in vain to brush away. There was no double vision. Her feet and hands felt very cold, so that even in August weather she was obliged to use hot-water bottles. There was no fever at any time, and she had had no pain except that described as occurring at the onset of the sickness. No cause could be assigned for the illness, except as hereafter to be stated. Her sister said, as regarded the time of appearance of the first symptoms, that she remembered the patient speaking of weakness of the legs some months before the final outbreak.

My notes of the physical examination are as follows:

The patient's appearance suggests a naturally healthy person. The pupils are unusually large in moderate light, but are equal and respond well to light; very slightly, however, with efforts of accommodation. The hands, in consequence of slight atrophy of their intrinsic muscles, show the "bird-claw" deformity in some degree, with an approach to the simian position of the thumb. The position of the right thumb can be voluntarily corrected somewhat, so that the thumb and little finger can be touched together. The left hand is worse than the right, and the interosseous muscles on the ulnar side of both hands are more affected than the others, so that the two smaller fingers remain crooked even when a strong effort is made to straighten them. The thenar eminence is also slightly wasted, but, on the whole, the appearance of atrophy is not marked. There is no marked change in the muscles of the right forearm, but the left forearm is cooler than the right, and measures one c.m. less, (right, 22.5; left, 21.5;) and the long flexor muscles on the ulnar side are somewhat wasted. The grasp with the left hand is weaker than that with the right, though both are weak.

The most striking symptom relating to the hands is, however, a high degree of inco-ordination of movement, associated with almost complete loss of the sense of position and impairment of the tactile sensibility, the latter, however, almost confined to the hands — and most marked at the ends of the fingers. The deep prick of a pin is distinctly recognized, but the point and head are distinguished with difficulty on light contact. Slight differences in temperature are distinctly recognized, even with the finger-tips. The inco-ordination is increased by closure of the eyes, but present even when the eyes are open. The loss of muscular sense is so great that the presence of a weight of fifty grammes held in the hand, with the arm bent at a right angle, is but just recognized with the left hand, and a weight of one hundred and fifty grammes is not felt with the right hand, although, in other respects, the right hand is in much the best condition. There is absolutely no sense of position of the hands, and, when the patient is not looking on, the fingers wander off in constant movement. The thumb and forefinger are less clumsy than the other fingers. The gait is now practically normal, though the legs are said to tire more easily than formerly. The muscles of the calves are rather flabby and small, but the patient can raise herself on the ball of either foot alone. She can also balance herself fairly well on either foot, and the difficulty in doing this is not much increased by closure of the eyes. The cutaneous sensibility of the legs (left alone tested), is slightly, but very little diminished. A light touch often passes unnoticed, but the prick of a pin is distinctly recognized, and the æsthesiometer points are distinguished at a distance of one and a half to two inches. The knee-jerk is markedly exaggerated on both sides, and the "front-tap" contraction is well marked. No distinct ankle-clonus is brought out by the usual methods of testing, but "trotting" of the leg is easily excited, and has been noticed by the patient herself. There is also some exaggeration of the myotatic irritability of the forearm muscles.

I will here remark that whether this increase in the myotatic irritability indicates an involvement of the spinal cord or not, it has several times been observed in cases diagnosticated as multiple neuritis (Möbius, Strümpell, Brissaud, and others), and I have myself seen it repeatedly in undoubted cases of lead-poisoning.[6]

The electrical examination shows the reaction of the ulnar nerves to be equal on the two sides, and nearly or quite normal to both currents, The inter-

[4] A similar rapid alternation of symptoms between the arms and legs is reported in Raymond's case.

[5] Loc. cit.

[6] Lead in the urine, etc. J. J. Putnam, Boston Med. and Sur. Jr., 1887, July 28th and August 4th.

osseous muscles and the opponens pollicis of the left hand react rather more readily than those of the right, in spite of being more atrophied. There is no degenerative reaction. Both disks look rather pale, but not beyond physiological limits. At a second examination I concluded that the right disk was normal. The left disk is more opaque than the right, though not absolutely beyond the limits of possible health. The vessels of the left disk show whitish lines along their borders, and there is, altogether, more connective tissue on the left than on the right disk. With the inverted image method, however, no difference in color is seen. The rest of the fundus is normal, and the media are clear. Fine oscillatory movements of the right eye are noticed during the examination.

This patient has been in the habit of drinking for a part of each year, and that during the winter season, water from a very old well which was sunk under the floor of the house, its exact position not being known. The water was pumped through a lead pipe, and was reported by Dr. A. M. Comey [7] as "bad-smelling and filthy," and containing "an enormous amount of lead, considering that it is used for drinking."

The urine contained no albumen, but a large amount of lead.

In spite of the fact that up to the time of my examination the patient had been steadily losing ground in the use of the arms (although, to be sure, the legs had improved spontaneously), she improved decidedly under treatment, so that, nine months later, her sister writes that she "can use her hands almost as well as ever, although there still remains some of the numbness, and she has not fully recovered her sight." According to later reports her condition has varied from time to time, and though much better, she is not entirely well.

The second case is that of a young lady of fifteen, in good circumstances, not of neurotic temperament or antecedents.[8] She was first seen by me in consultation with Dr. Wadsworth, of Malden, in April, 1887, for slight inco-ordination of the muscles of all four extremities, and difficulty in the use of the eyes. She gave the following history:

Her health had been good up to last fall, except for occasional headaches. Last fall and winter she had an increased number of headaches, each attack sometimes lasting several days, and the pain being referred to the forehead and vertex. On the day following one of these attacks she was very dizzy, but there was no nausea or vomiting. In the latter part of the autumn she had partial loss of control of the bladder, lasting several months, but ceasing when she stopped going to school, and going out into the cold. She left school in March, 1887, mainly because the teacher noticed that her eyes had a peculiar expression, and, perhaps, because there was some difficulty in reading, although the patient now thinks that she did not herself notice much trouble in reading at that time. For a few weeks previous to my examination, however, the patient had found it impossible to read, unless, perhaps, a line or two at a time, the words blurring and running together. She can recognize her friends, but has, as she says, "the greater part of the time," distinct diplopia. Since the middle of March she has noticed an unsteadiness of gait, and while walking feels dizzy, probably on account of the diplopia. With this there has been impairment of strength, noticed, for example, in sitting down or rising from a chair, and a sense of fatigue in the legs. About Christmas time the ends of the fingers of the right hand felt numb and prickly for a week or so, but there was no difficulty in using them. The left hand began to be numb about the middle of March, at the same time with the onset of the symptoms above described, the numbness affecting mainly the fingers, but also the whole hand from the wrist downward. This numbness was persistent, not accompanied by pain, and disappeared about ten days before my examination, passing away quite suddenly.

The notes of my physical examination are as follows:

April 8, 1887. Slight but well-marked ataxia in both the upper and lower extremities. Grasp of both hands weak; left much weaker than right; left leg also weaker than right. Patient can stand on either leg and balance herself fairly well, even with her eyes shut. A staring expression of the eyes is very noticeable and there is well-marked diplopia. On examination it was found that the right eye cannot be moved inward much beyond the median line, and only very imperfectly upward and downward. The motion outward is perfect, or nearly so. All the motions are accompanied with more or less jerking of the eye-ball. The left eye is in a similar condition, but all its movements are better preserved. The pupils react well to light. Vision of the right eye is much impaired, so that print which can be seen at about eight feet with the left, is seen only at about two feet with the right. Field of vision but little, if at all, impaired. Knee-jerk exaggerated on both sides, and imperfect ankle clonus present. Attention is called to the fact that the right eye and the left limbs are the worst. Patient is said to be more dull and apathetic than before her sickness began, though not so much so now as at an earlier time.

An opthalmoscopic examination was made, and seemed to show an abnormal paleness of the disks. At a subsequent examination, however, made a month later under more favorable conditions, the disks appeared normal, and as, by that time, the eyesight had become almost completely restored, it seems highly probable that the original difficulty of vision was one of accommodation only. At the first examination some of the muscles of the left arm seemed to be somewhat wasted, but the difference may perhaps have been no more than natural.

On May 26th, seven weeks later, the report of her condition was as follows: Better in every respect. Thinks the hands are as well as ever. No staggering. In fact, the only difficulty that seems to remain is a slight trouble in reading. On examination it is ascertained that there is double vision only when the eyes are carried far to the left, and under those circumstances the right eye is noticed to twitch slightly.

On electrical examination the reaction of the muscles is found apparently normal, that is, there is no essential difference in reaction between the flexors and extensors of either arm. None of them, seem to react quite as rapidly as those of health but this is uncertain. The flexor muscles of the left arm are not quite so large as those of the right, but the grasp is nearly, if not quite, as good.

On examination of the urine of this patient, lead was

[7] Vide Lead in the urine, etc. Loc. cit.

[8] This case has been already reported (loc. cit.), but I give it again at somewhat greater length for the sake of completeness.

found to be present. The only source from which lead could have come is indicated in the inclosed letter from Dr. Wadsworth.

"Mr. G. told me after you had gone, that, last summer, during July and August, the family spent a couple of months at ————, where he built a house and drove a pipe some seventy feet for water. The sections of pipe were screwed together, and the joints covered with white lead, so that a good deal of lead would be left on the inside of the pipe, and this supplied the house with water."

Still later the patient reported herself at my office perfectly well in every respect.

The third case was seen by me in consultation with Dr. Francis, of Brookline, on January 13, 1887. The patient was a lady in good circumstances, forty-five years of age. She was passing through the menopause at the time her sickness began. Up to October, 1886, her health was pretty good. At that time she began to show signs of a peculiar form of indigestion, and very shortly afterwards had uncontrollable vomiting, which lasted about six weeks, and was so severe as to make it necessary to feed her by rectal injections. This condition at last passed quickly away, and she became able to take every kind of food as well as before. Then occurred what seemed to be a sort of hysterical mania, in which she was seen by Dr. F. Minot, in consultation, and although the worst phase of this soon passed off, she had never since been in her normal state of mind, behaving rather childishly, and taking her illness more lightly than might have been expected. During the height of the attack, and even after that, she had some incontinence of urine at times. A few weeks before my examination the present condition developed itself.

My report of the physical examination is as follows:

The patient sits in a chair with an indifferent expression and no appearance of suffering. The legs are bent at the knee, and the left cannot be fully extended. There is marked ataxia of the hands, increased by closure of the eyes. All movements are possible of all four extremities, but feeble. There is some tenderness on deep pressure in the calves, especially the left, but not of the nerves in the popliteal space. The knee-jerk is absent (except that it was obtained once to a slight degree on the right side). The temperature of the skin of the legs seems normal. There is great muscular relaxation everywhere, and great general emaciation, but no atrophy. The tongue protruded straight and without tremor. There is no lead-line. The heart is normal, but weak. The patient is unable to stand alone, but this probably proceeds more from deficient innervation than from weakness. Sensibility to touch or pricking normal on the hands. No ocular symptoms.

The patient was advised to enter the Adams Nervine Asylum, where, in the course of some months' treatment, she gradually improved, although even now, at the expiration of fourteen months, she walks only with crutches, and then with some difficulty, and has still some inco-ordination in the use of her hands.

Dr. S. G. Webber, under whose care she passed, has been kind enough to send me the following notes. I should say that I did not make the diagnosis of neuritis, because I thought that the local symptoms were insufficient, but concluded, erroneously, as I now believe, that the symptoms were of functional nervous origin. Dr. Webber after careful examination, concluded that neuritis accounted for many of the symptoms at least. He did not, however, exclude the possibility of central disease as well.

"When she came to the asylum Mrs. L's condition was as follows: Pupils, eyes, facial muscles and tongue moved naturally. There was slight inco-ordination of the hands, but no tremor when extended. Sensation was only slightly impaired at that time, but later seemed to become more so. There was impairment in the sense of localization in the feet. No patellar reflex. No ankle clonus. Left leg was contracted, slightly flexed at the knee, and its strength was less than that of the right leg. The peronei muscles reacted but very slightly to the faradic current, the vasti interni scarcely at all, the interossei and the long flexors of both hands very much less than normal; the rest of the muscles reacted better. The mental condition was peculiar. There was an unusual degree of childishness. The memory was weak. It was not possible for her to read any long paragraph or article. During her stay she improved mentally, but the memory for recent events remained impaired throughout. At one time, while taking iodide of potassium, she had much tingling in the fingers, and even pain, so that I diminished the dose. At first there was hyperæsthesia of the muscles on pressure. She gained very slowly in all respects, but before she left us the electric reaction had improved, except those of the vasti interni.

The treatment consisted in iodide of potassium, five grains, three times daily; later, two and a half grains; massage, electricity, and symptomatic treatments of various kinds.

Lead was found in Mrs. L.'s urine, once, in such large quantity that I thought there must be an error, especially as there had originally been tin foil over the cork of the bottle. I then took extra precaution to exclude accidental sources of contamination, but lead was again found in large amount."

The symptoms to which I would especially call attention in these cases are the following:

First. The rapid spontaneous improvement of the legs in the first case at the time when the arms were still growing worse; and, in the second case an eventual improvement so rapid that it might suggest that we had to deal with functional and not organic disease. It is, however, well known that an equally rapid improvement has previously been reported in cases of this kind. As an instance of this sort I will call attention to the case cited above from Raymond, as well as to another very interesting case reported by Lilienfeld in the *Berliner Kl. W. schr.* for 1885, page 726.

Second. The exaggeration of the knee-jerk, to which I have already referred, and the bearings of which I have discussed elsewhere.[9]

Third. The serious character and protracted course and possibly central origin of some of the symptoms in cases I and III.

The class of cases to which special reference has been made in this paper are mostly curable, or at least susceptible of great improvement, though sometimes their symptoms are of long duration, and some of them may persist indefinitely. Partly on account of this curability, it has been assumed that the peripheral nerves are the chief seat of the disease, so

[9] Loc. cit.

far as the motor and sensory symptoms are concerned and that the spinal cord is nearly, or quite, unaffected. How far this conclusion is justified, we have not as yet sufficient material to decide. The myelitic changes, if they exist, are certainly not of a progressive type. The differential diagnosis, however, between these cases and the early stages of certain others of really spinal origin, and of progressive and fatal course, is by no means always easy.

A typical case of true locomotor ataxia, by the time it has reached the ataxic stage, usually presents enough distinctive features to make this error impossible, but sometimes the posterior columns of the cord, either alone or in combination with other tracts, become diseased in such a way that inco-ordination comes on quite rapidly, attended by alterations of the sensibility, beginning in the hands and feet, and sometimes by amyotrophic or paralytic symptoms, not altogether unlike those which are due to multiple neuritis.

A case where this doubt as to the diagnosis might be entertained, especially in view of the recovery of the patient, is quoted by Leval-Picquechef, from a communication by Raymond, who had made the diagnosis of *diffuse subacute myelitis, involving principally the posterior columns.* The patient was a man, forty-two years of age. Two weeks before the examination he felt, on arising in the morning, sensations of prickling and numbness in the arms; in the afternoon his legs became weak, but not so as to prevent walking; next day he was unable to stand, and lay in bed suffering from formication in the extremities, worse at night; pains in the legs and muscular twitching, and headache. On examination, he was found to have slight paresis of the left side of the face, and slight difficulty in speech, and in deglutition; the muscles of the legs were tender on pressure; the tactile sensibility was slightly diminished, and there was a certain degree of delay in the sensitive conduction from the inner side of the foot. There was also marked inco-ordination in the lower extremities on attempting to walk; and the knee-jerk was wanting. This patient remained under observation for a little more than three months, at the end of which time he had almost entirely recovered.

Another case which is suggestive from this point of view is one which I have lately had occasion to observe myself, through the kindness of Dr. M. A. Morris, of Charlestown. The patient was a woman of seventy-three years, who had been excessively anæmic, and for two years before my examination had felt sensations of numbness and prickling in some of the fingers of both hands, gradually increasing in severity. A few weeks before I was asked by Dr. Morris to examine her, she had been attacked rather suddenly with inco-ordination of movement which at first affected mainly the lower extremities, but, later, the upper equally. This increased rapidly, so that she soon became confined to bed. Besides the inco-ordination, there was great impairment of sensibility in all its modes. The lower extremities soon became entirely paralyzed, but this was due, mainly, to the development of acute myelitis in the dorsal region, which may be regarded, for the purposes of the present argument, as an accidental complication, although it was eventually the cause of the patient's death, which occurred a number of weeks later.

The examination of the spinal cord showed a destructive degeneration of both the posterior and lateral columns throughout their whole extent, both above and below the seat of the acute myelitis. In this case the knee-jerk was greatly exaggerated, but, as we have seen, it is not safe, for this reason, to exclude the possibility that peripheral neuritis may be the prominent pathological condition and the prognosis favorable.

It is doubtless true that in most cases a careful study of the symptoms, etiology, and history will enable us to reach a satisfactory diagnosis in these doubtful cases, but it is also true that, considering the great differences in the clinical pictures presented by different cases of peripheral neuritis, and the long duration of some of the symptoms, it might easily be possible to mistake a pseudo-tabes of this origin for the early stage of incurable myelitis, and vice-versâ.

Finally, it must be admitted that when we say that we believe the symptoms in a given case to be due to arsenic, lead, etc., we must as yet, considering the small number of cases that have been reported, tacitly make the reservation that the disease and the exposure may perhaps have been coincident only.

RECENT PROGRESS IN OPHTHALMOLOGY.

BY MYLES STANDISH, M.D., BOSTON.

THE PUPIL SYMPTOMS MET WITH AFTER HEAD INJURIES.

Jonathan Hutchinson, Jr.,[1] in a review of the pupillary symptoms met with after head injuries based principally upon cases in the London Hospital, says: "A warm discussion has lately been held as to whether the human iris possesses any dilator fibres, the affirmative being maintained by Iwanoff, Merkel, Jeropheeff, and Henle, whilst Grünhagen resolutely denies the existence of any such muscles, and is supported to some extent by various observers."

Dr. Gaskell sees "no urgent necessity for a special musculus dilator pupillæ; variations in the extent of the contraction or relaxation of the sphincter are quite sufficient to account for all the differences in the size of the pupil, if only the radial fibres of the pupil possess, as Grünhagen thinks they do, a sufficient amount of elasticity." Dr. Gaskell points out the close resemblance of the nerves which dilate the pupil to those which inhibit the circular muscles of the intestine, and hence speaks of the former as the "cervical splanchnic," although, perhaps, it would be more convenient to use the term pupil inhibitor. The existence of such inhibitory action on the part of the cervical sympathetic, will probably come to be universally admitted, although there may be in addition dilator fibres, the existence of which in birds and certain other animals is not denied. As Gaskell observes, "The attempt to attribute dilation of the pupil to contraction of the bloodvessels of the iris, is for several reasons, not worthy of discussion." (See also these papers, August 5, 1886).

PUPILS IN CONCUSSION OF THE BRAIN.

During the collapse stage the pupils are neither contracted nor dilated, and they respond to strong illuminations, but not infrequently the pupils tend towards slight myosis, and inequality is occasionally

[1] Ophthalmic Review. Vol. VI, Nos. 66, 67, 68.

seen. Whatever view be taken, as to the condition of the cerebral circulation (and both extreme congestion and anæmia have been found in cases after death from concussion), it is not doubted that the cerebral functions are, to a more or less complete degree, suspended by the violent shaking that the brain undergoes. Hence the condition of the pupils would be expected to be the same as during sleep and the anæsthetic stage of chloroform inhalation. In a few cases of concussion fixed mydriasis on both sides is noticed. Our author thinks that possibly this may be due to an irritation of the nerves of the dura-mater as Bochefontaine found that on irritation applied to the dura-mater in dogs there was a decided temporary mydriasis, but also draws attention to the fact that Dr. Ferrier has found that irritation of the posterior part of the superior frontal convolution of either side is followed by dilatation of both pupils, attended with movements of the head and eyes. Where there is one-sided mydriasis following concussion, two cases are cited to show that occasionally they are to be explained by injuries to the third nerve or its nucleus. In the after-results of injury to the cortex and deeper parts of the brain, it is the general rule that with the onset of inflammatory reaction, the pupils become strongly contracted, although the lesion may be at some distance from the corpora quadrigemina.

COMPRESSION OF THE BRAIN AFTER HEAD INJURIES.

Surgical authorities are agreed as to the grave importance of insensitive and dilated pupils as a symptom of compression of the brain after head injuries, as pointed out many years ago by Guthrie. During the first onset of middle meningeal hæmorrhage, however, the pupils may still react to light, and whilst they do so, the compression of the brain is probably in a recoverable condition if trephining is immediately performed. Whilst double dilatation may be a symptom materially affecting the prognosis, fixed mydriasis on one side only, may with very strong probability, be taken to indicate that the hæmorrhage is occurring on the same side as that on which the pupil is affected. However, as has already been stated, one-sided mydriasis may occur from other lesions than compression. The current view with regard to the pupil symptom of compression, which was suggested by Hutchinson Senior, and endorsed by Jacobson, attributes it to pressure on the third nerve by blood-clot, situated about the cavernous sinus or just behind. This view our author combats and shows by the citation of cases that one-sided mydriasis is not due to pressure on the third nerve, but is probably to be ascribed to pressure on some cerebral centre. Probably pressure transmitted to the corpora quadrigemina must be taken as the explanation. That pressure occasionally produces irritation, and not paralysis of the pupil centres, is probable.

COURSE OF THE CERVICAL SPLANCHNIC.

The "cervical splanchnic" in its course to the eye was formerly assumed to pass through the lenticular ganglion, but of late some slight doubt has been thrown upon this. Hutchinson thinks that in man this nerve probably passes from the first or second dorsal nerve to join the cervical sympathetic cord, and bases his opinion upon the following case: the patient aged 54, was crushed between a railway-engine and the wall, as a result of which the three upper ribs on the right side were fractured. When a strong light was thrown upon the eyes the pupils were equal, but upon removing the light the right pupil dilated only to 3½ mm., the left to 4½ mm. On the right side the palpebral fissure was decidedly smaller than on the left, owing no doubt to paralysis of the Müllerian muscle, but the relative protrusion of the eyes appeared to be about equal. These pupil symptoms contined until his discharge one month later. The effect of atropine and cocaine agreed with what one would expect from the results of Koller, Jessup, and others. On instilling a five per cent. solution of cocaine, the left pupil dilated, whilst the right remained the same size; atropine, however, caused it to dilate from 4 to 6 mm.

OPHTHALMOPLEGIA EXTERNA.

Westphal [2] records a case of chronic progressive paresis of the ocular muscles (ophthalmoplegia externa), with a description of ganglion-cell groups in the region of the ocular-motor nucleus. The patient was a man forty-four years of age. In August, 1881, he had an attack of loss of consciousness, with paralysis of the right arm, which, however, recovered its power in a few days. This attack had been followed by others of a similar nature. There were two distinct scars on the penis, but the patient denied syphilis, of which there was no other evidence. When first seen by Westphal, in September, 1882, the ocular condition was as follows: The left eye was, through ptosis, half shut; there was little difference in the sight of the pupils (the left being slightly smaller than the right), the right reacted only very slightly to light, and the left not at all; there was a well-marked strabismus divergens, together with a complete paralysis of all the ocular muscles; the eccentric vision was good in both eyes; the vision of the right eye was not to any degree diminished, and the left eye was diminished about two-thirds; diplopia had been present. In February Dr. Uhthoff had noted that the papillæ were somewhat whiter than normal, and also, in April and May of the same year, that the temporal halves of the papillæ were distinctly whiter than the nasal halves. The arteries on both sides were somewhat diminished in size. Later the pupils did not react in the slightest to brilliant illumination. The accommodation was not affected. The fields of vision were of normal size.

In September, 1883, the pallor of the optic nerves had not increased, and progressive optic atrophy could not be said to be present: The tongue was protruded straight, but was partially atrophied, and showed slight fibrillary tremor; the speech was peculiar, but not characteristically paralytic; sensibility of the face diminished; taste uncertain; smell nearly lost (chronic nasal catarrh); the lower extremities were not wasted; gait fairly firm; the patella tendon reflex could not be produced upon the right side, and was barely noticeable on the left; cremasteric and abdominal reflex on both sides; upper extremities not markedly affected; the patient had melancholia, which persisted until his death, which resulted from pneumonia and œdema of the lungs, in October, 1883.

Autopsy. The pia mater was markedly œdematous and thickened. There was atrophy of the abducens, oculo-motor, and trochlearis nerves. Fatty degenera-

[2] Archiv für psychiatrie, Bd. XVIII., Heft 3.

tion of the ocular muscles on both sides. Gray degeneration of the posterior columns of the cord. Marked cylindrical widening of the ascending aorta, with much atheroma. Examined microscopically, the oculo-motor nucleus showed advanced degeneration, very few ganglion cells remaining and these much shrunken in appearance. The ocular muscles and nerves were in the highest degree atrophic.

It is interesting to note, in connection with the ophthalmoscopic appearance of the papillæ during life that the condition of the optic nerves was not that of simple atrophy such as is found in cases of tabes. The sections were made from a portion of the nerve just behind the bulb, where the bloodvessels lie in the centre of the nerve. The changes consisted in a thickening of the connective tissue septa, which extended into the very finest sub-divisions. The process only occupied a portion of the periphery of the nerve, the rest was healthy.

GANGLION-CELL GROUPS IN THE REGION OF THE OCULO-MOTOR NUCLEUS.

The following anatomical appearances are of especial interest as being described for the first time. Behind the atrophic oculo-motor nucleus, and in the upper part of the column of the nucleus, as far as the posterior commissure, were found, in a whole series of sections, and lying on both sides of the raphe, a peculiar group of ganglion cells (median). The group had an oval form, with the long axis partly parallel, and partly oblique to the raphe. Further in, another series of sections made laterally to the "median" group, but at a little distance from it, was found another group of ganglion cells (lateral), also oval in form, with the long axis horizontal. The ganglion cells of both were everywhere abundant, and much resembled those of the oculo-motor nucleus. The "lateral" groups are separated by a fine band of nerve fibres passing downward to the crusta of the cruscerebri, which are evidently continued from the cells of the above groups. This band widens out above, and, with the raphe, completely surrounds the "median" group of cells.

Westphal thinks that it is probable that these cell groups give origin to oculo-motor fibres, and calls attention to the fact that such groups have been described by Gudden, Darkschewitsch, and others, in newly-born animals and human embryos. With regard to the physiology of these groups, in this case the ocular motor nucleus was entirely degenerated, and that the external ocular muscles were all degenerated, while per contra, the internal ocular muscles, the ciliaris and sphincter papillæ, were healthy, and from these facts it is suggested that these muscles are innervated by the cell groups he describes.

Eisenlober,[3] on the other hand, reports a case of ophthalmoplegia externa progressiva and final bulbar paralysis, with an entirely negative autopsy. The patient was a girl, of eighteen years of age, and any acquired or hereditary syphilis was in the highest degree improbable. The patient was of neuropathic disposition, and had suffered, even when a little child, with migraine as often as twice a month, and later as often as twice a week, typical attacks, first on one side of the head, then on the other, accompanied by vomiting, and continuing generally twenty-four hours. It was impossible to ascertain whether the attacks of ocular muscle paralysis coincided, either in the commencement or in their recurrence, with the attacks of migraine. Two years before seen the patient had become suddenly diplopic, and the physician who then saw her said that the muscles of the right eye were impaired. Under the use of potass. iodid., the diplopia vanished in three weeks. This diplopia reappeared from time to time during the summer of 1885. At this time there suddenly appeared ptosis, on the left side. This recovered under potass. iodid., but returned upon the left side, and subsequently changed from time to time. In July, 1886, after a very severe attack of migraine the patient suddenly noticed a weakness of both hands. In August there appeared a slight weakness of both legs, together with dyspnœa upon quick motions, and difficulty of deglutition and of speech. There was no hyperæsthesia or paræsthesia. Vegetative functions normal. Upon the 16th August, 1886, when Eisenlober first saw the patient, he found an incomplete ptosis on both sides, but somewhat more marked upon the left. Reaction of the pupils to light prompt. Accommodation normal. Both globes nearly motionless, but the left turned somewhat outward. No diplopia. Both lids could be closed, but it required a little effort. There was slight paresis of the facialis, especially for voluntary movements. The tongue was protruded straight, but with slight vibrations to the right side. Deglutition difficult. Weakness of various muscles of the hands and legs. Knee-jerk present. Triceps and forearm reflex felt on both sides. Sensibility remained everywhere.

A diagnosis was made of a chronic degeneration of nerve cells in the oculo-motor nuclei, together with the deeper motor nuclei of the bulb, and the anterior gray horns of the cord.

The autopsy was made twenty-four hours after death. The oculo-motor, abducens, trochlearis, and also the branches of the facialis were a clean white, and of normal size. The medulla oblongata, the pons, the region of the nuclei, of the eye muscles, were stained with carmine and Weigert's solution, sections made and examined with an entirely negative result.

[3] Neurol. Centralblatt, 1887, Nos. 15, 16.

MIGRAINE FOLLOWED BY TEMPORARY PARALYSIS OF THE THIRD NERVE.

Suckling[4] reports a cure of paralysis of the third nerve, following attacks of migraine. The patient was a youth, aged 18. Since infancy the patient has been subject to severe headaches, occurring at varying intervals. During the last four years the attacks had occurred more frequently, and had been more severe, and for the past two years he has had an attack pretty regularly every fortnight. An aunt of the patient suffered from severe periodical headaches, but neither of his parents suffered from any neurosis whatever. An attack lasted two days, and took the following course: He first felt a slight pain above the left brow, which gradually increased in intensity, and was followed by a flow of saliva into the mouth, and he felt cold; the pain increased gradually, and attained its maximum in twenty-four hours; it then gradually subsided, and ended completely in another twenty-four hours; the pain remained localized over the left brow; he did not vomit, and there were no ocular spectra or paræsthesiæ of any kind; after an attack the scalp was tender.

The left eyelid was first noticed to droop after an attack in infancy, and this has occurred very

[4] Brain, July, 1887.

frequently since. Three years ago, after a severe attack, the left eye was completely closed, and the eyeball turned outward. The eye was not affected in the milder attacks. The eyelid begins to drop at the end of an attack, when the pain is wearing off. The lid takes twenty-four hours to drop completely, and in another twenty-four hours has completely recovered. The eye is not always turned outward, but it has been on two separate occasions, and then the paralysis lasts longer, not recovering for a week after the attack. The mother attributes the increased severity of late to attendance upon a night school the past two years. On examination a week after an attack, the left pupil was a little larger than the right, and responded normally to light and accommodative efforts. The left palpebral fissure was a little smaller than the right, and the upward movement of the eye was defective, there being diplopia in looking upwards. The patient complains that the sight of the left eye is not as good as the right; but Dr. White reports that the vision is normal, and that when he first saw the boy there was complete paralysis of both the internal and external muscles of the eye which are innervated by the third nerve.

ORTHOPEDIC TREATMENT OF PARALYSIS OF THE OCULAR MUSCLES.

Bull [5] has tried the method proposed by Professor Michel (see these papers April 11, 1876), and reports twenty-one cases, with the results obtained, most of them being palsies of the external rectus, of syphilitic or rheumatic origin. The duration of the paralysis varied from a few days to ten years. Complete cure was effected in eight cases, notable improvement in six others, and in seven the treatment seemed valueless. Most of the recoveries occurred in recent cases, though in some a cure was effected after the complete failure of drugs and electricity to accomplish it.

RECURRENT PARALYSIS OF THE MOTOR-OCULI.

Wadsworth has published a very interesting paper upon recurrent paralysis of the motor-oculi, which appeared in the *Boston Medical and Surgical Journal*, Nov. 24, 1887.

THE CORRECTION OF SQUINT.

Landolt [6] writes that the agents for the correction of squint are atropia, glasses, cessation from work, orthoptic exercises, and operative interference. He never operates without satisfying himself that he has gotten the full effect of non-surgical measures. If the correction is made in a child, while young, without these precautions, divergence may occur later. It is difficult to determine beforehand just how much to do. It is easier to diminish than to increase the effect. Dr. Landolt never operates on two homonymous muscles at once. He rather does a tenotomy of one and an advancement of its antagonist. The remedies for over-effect in operations for convergent squint are stoppage of atropia, removal of stitches from advanced muscle, and use of the other eye. No case should lose its power of convergence or divergence after operation, as without that power binocular vision would be impossible. If divergence persist, advance the tenotomized muscle. This can easily be done on the tenth or twelfth day.

PATHOGENESIS OF PTERYGIUM.

Theobald [7] writes that if the generally accepted theory of the pathogenesis of pterygium that it has its origin in a marginal corneal ulcer were true, pterygium would be found approaching the cornea from every possible direction. It is known, however, such is not the case, but that it is almost always situated directly over the recti muscles, and that in a very large proportion of such cases it is over the rectus internus. He draws attention to the close connection between the vessels of the recti muscles and those of the anterior portion of the conjunctiva, and points out that the determination of blood to these muscles might influence the blood-supply of the overlying conjunctiva, and that this would be the case especially with the recti interni, since they were the largest of the straight muscles, and in close relationship with the conjunctiva, because attached to the sclerotic nearer to the corneal border than any of the others. The muscles, he regarded as the usual cause of pterygium, through the localized hyperæmia of the conjunctiva to which they gave rise.

Clinical Memorandum.

FATAL TONSILLAR HÆMORRHAGE.

BY J. N. HALL, M.D., (HARV.), STERLING, COLORADO.

THEODORE W., about twenty-six years of age, cow-boy. Attacked with quinsy, he says, two weeks ago, and bled severely from the mouth. Does not know origin of the blood, which, he says, amounted to over a quart. Was about twenty miles from a physician, and did not consult the writer until he had bled slightly at several other times. Wishes now, October 30th, to know "what to take to get strong again."

At this time there had been no bleeding for several days, and the left tonsil, although somewhat swollen, was not very troublesome. He was given tincture of the chloride of iron, with fluid extract of ergot. After two days, feeling better, he went away from town to the ranch, forty-one miles distant.

The next day but one, and during the absence of the writer, he returned, reporting three severe hæmorrhages. He was very pale and weak. Dr. C. S. Stone found the origin of the blood to be in the right tonsil, in a cavity left by the evacuation of matter during the attack of quinsy. He applied styptics and no bleeding took place for ten hours. The patient was instructed to press upon the tonsil, in event of bleeding, with the finger. At 10 P. M., and at midnight bleeding occurred, but was checked before arrival of medical aid by the above plan. With the assistance of Dr. Stone, subsulphate of iron was applied to the interior of the cavity. The patient in each hæmorrhage lost, by the writer's estimate, about twenty ounces of blood. He was now pulseless at the wrist, extremities cold, and the heart's action very feeble, 150 per minute.

The left tonsil was now greatly swollen, and a little matter was evacuated with a broad exploring needle. Two days later a decomposing clot, nearly as large as a hen's egg, was coughed from the throat, and the tonsil returned to nearly its natural size.

[7] American Journal of Ophthal., Vol. IV., No. 8.

For eleven days the patient improved, and was considered out of danger, having been on the street daily for a week.

I was called suddenly at 2 P. M., October 16th, to go a distance of one hundred and sixty-five feet, to see a very sick man. The time occupied in going was extremely short, but it proved to be this patient lying on the floor moribund. No blood had been lost on the street, but during the time the writer walked the distance named, the patient had lost blood so rapidly by the mouth and nostrils as to be so far gone that no measures of relief were taken, because considered utterly useless. As the writer entered, a stream of blood as large as could flow, came from the mouth and nostrils, but it stopped shortly. The pulse was perceptible for a few seconds only after arrival.

No post-mortem was obtained. It would seem impossible for death to occur so suddenly from a hæmorrhage from any vessel less than the internal carotid. It was learned after death that the patient had stated a short time before that he felt "something swelling in his throat."

Probably the ulceration weakened the wall of the carotid artery, and the bleeding came from an aneurismal dilatation of the vessel at that point. Such rare cases have been previously reported.[2]

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

NOVEMBER 28, 1887, the President, DR. O. F. WADSWORTH, in the chair.

DR. J. J. PUTNAM read a paper entitled,

LEAD-POISONING AS A CAUSE OF MUSCULAR INCO-ORDINATION (PSEUDO TABES.)[1]

DR. S. G. WEBBER said that pseudo tabes seemed hardly an appropriate name for this series of cases, and he thought none of them were likely to be mistaken for cases of that disease. In the first two, tendon-reflex was present, and the whole group of symptoms differed from those of tabes. In the third case the whole history was widely different.

They were all remarkably well reported and interesting cases of lead-paralysis, affecting the nerves and possibly the spinal cord, and in the last case the brain. There are cases of lead-paralysis, due probably to neuritis, which might be mistaken for locomotor ataxia, as some to which the reader has referred. In many cases, however, it is by no means certain where the lesion is situated. In the third case reported, the brain was much affected, as shown by the inability of the patient to apply her mind, the loss of memory and the childishness of the mental processes. It is possible that the spinal cord was also affected. That there was not extensive organic lesion is shown by the fact that the patient slowly regained her strength and mental powers. She can now walk with crutches and a short distance without. She is able to read, her memory has improved and there seems to be no reason for doubting a still greater gain will be be obtained.

It is well to bring the subject of lead-poisoning to the attention of the profession at frequent intervals. The symptoms are so multiform and varied, two cases rarely being alike, that unless the physician is constantly on his guard he will make mistakes. The danger from the frequent ingestion of small quantities of certain poisons during a long period of time needs to be emphasized again and again.

DR. C. F. FOLSOM had seen cases of neuritis which he supposed to be due to lead, but not with such symptoms as to lead to difficulty in differential diagnosis between posterior spinal sclerosis and neuritis. His cases, of which he mentioned two, in particular, which simulated what is usually called hysteria more nearly than any forms of organic disease; were clearly of peripheral origin. In other forms of neuritis, however, and in certain cases of locomotor ataxia, he had found the usual symptoms so obscurely marked as for some time to give rise to doubt in diagnosis. He referred especially to cases of posterior spinal sclerosis which, in his experience, had followed soon after syphilis, within five years, in which the usual subjective symptoms had been entirely absent; where the diagnosis could be safely made from the presence of objective indications leaving no room for doubt.

DR. J. H. DENNY remarked that the use of the term "pseudo tabes" was indeed sanctioned by writers of eminence, but that he should have the same disinclination to employ it as to speak of pseudo typhoid or pseudo phthisis. It comprehends, nevertheless, a class of symptoms more or less imperfectly resembling tabes dorsalis, which are usually ascribable to some toxic agency, as lead or alcohol.

In one case that came under the speaker's observation for several years, that of a painter who had recurrent attacks of the symptoms of lead-poisoning, and who was under his care at the city hospital; the symptom of muscular inco-ordination, in the form of ataxic movements of the hands, appeared only during the last attack, and disappeared in a few weeks under treatment.

In another case, that of a woman suffering from lead-poisoning, there was ataxia of the legs, and aphasia ataxia, with the symptoms of paralysis of the extensor muscles of the forearms and legs, and of vertiginous attacks.

In both of these cases there was an absence of the patella tendon reflex. Many of the symptoms of tabes dorsalis appeared in cases of peripheral degenerative neuritis of toxic origin, which the speaker had observed, such as paralysis of the ocular muscles, nystagmus, swaying or inability to stand with closed eyes, sluggishly reacting pupils, simulating the Argyll-Robertson symptom, obscure disturbances of sensation, loss of the patellar reflex, some pain, and sometimes inco-ordination.

One of the cases reported by the reader was associated with a lesion of the central nervous system. Circumscribed minute hæmorrhages into the brain or cord have been found in lead-poisoning, and Vierordt[2] has recently referred to the question as to whether the secondary descending degeneration of the posterior columns of the cord, which might follow, would produce symptoms of tabes. He states his own opin-

[1] See page 596 of the Journal.

[2] Pepper's System of Medicine, Vol. II, p. 383. Gaz. Méd. Paris, 1878, p. 42.

[2] Zur Frage der Bleilähmung. Archiv. für Psychiatrie u. Nvhlk, Bd. x viij, Hft. 1.

ion that lead, in the vast majority of cases, does not affect the cord pathologically, but that when it does so, evidence goes to show that the effect is limited to the anterior gray cornua.

The pathology of these cases is not yet determined, and the hypothesis that the ischæmia resulting from lead-poison may produce functional disturbance of co-ordinating centres, and the phenomena of transitory inco-ordination of muscular movements seems plausible. Westphal,[1] however, has quite lately advanced the opinion that tabes dorsalis may in rare instances have a sudden origin, consecutive to a cerebral lesion succeeded by secondary descending degeneration of the posterior columns, as referred to by Vierordt. The speaker said that as he regarded tabes dorsalis as essentially due to a primary lesion of the posterior columns, and early characterized by marked disturbances of sensation such as is not characteristic of pseudo tabes, he preferred to classify such cases variously as those of lead encephalopathy, secondary degeneration of the posterior columns, toxic spinal paralysis, or toxic peripheral degenerative neuritis, etc., according to the development of the symptoms.

The name, however, is of minor importance, the really important thing being to arrive at a more accurate pathology. The cases reported by the reader with accompanying pathological and histological demonstration are both an interesting and a valuable contribution toward this object.

DR. P. C. KNAPP considered the paper a valuable addition to our knowledge of the still obscure subject of chronic lead-poisoning. He had never had the opportunity of seeing a case of ataxia from lead neuritis although he had once seen a man in Dr. Webber's service at the City Hospital, when he was house-officer there, who had typical lead colic. He was a worker in lead and this was the second attack. Careful examination, however, revealed the absence of the knee-jerk, Argyll-Robertson pupils, and Romberg's symptom, while inquiry brought out the history of "rheumatic" pains. He agreed with Dr. Webber in criticising the term "pseudo tabes" for Dr. Putnam's cases. They did not resemble the pseudo tabes from alcohol, arsenic or diphtheria, for in the latter cases the knee-jerk is absent. In all the cases of multiple neuritis that he had seen, and in the great majority of those reported, the knee-jerk has been absent or diminished. Dr. Putnam's cases were furthermore interesting as showing the existence of marked sensory symptoms. Lead seems to have a propensity for attacking the purely motor fibres, and Tanquerel states that lead-anæsthesia, although it is sometimes seen in lead-paralysis, is a rare affection. Most writers state that as a rule there are no sensory disturbances in lead-paralysis. He agreed with Dr. Folsom in thinking that in many cases of true tabes-dorsalis the early symptoms were not so definite as Dr. Putnam had implied, although he had not been able to note the difference between cases coming on five years, and those coming on ten or fifteen years after syphilis, partly from the difficulty of getting a definite history of syphilis. He had, however, seen many cases where the symptoms were explained only by the discovery of the loss of the knee-jerk, the changes in the pupils, optic atrophy, or Romberg's symptom. One of the last cases of tabes that he had seen, complained only of a localized pain and soreness near one tibia, worse at night. There was no periostitis or admitted history of syphilis, but the patient, a woman, had Argyll-Robertson pupils and no knee-jerk.

DR. W. N. BULLARD referred to the existence of somewhat severe but quite obscure forms of lead-poisoning, and related the history of a hospital case, that even after a careful examination, presented apparently nothing but great debility. The patient, a man of thirty-five, had no history of either syphilis or alcohol. The eyes were examined with negative results. The urine contained much lead and as the weakness was great, the man was admitted into the wards of Dr. Doe, where under treatment for lead, he rapidly recovered strength.

DR. PUTNAM said in conclusion, that he did not care in the least to defend the name of pseudo tabes, and had used it simply for convenience sake. At the same time, he thought that its use was justifiable at present, on the ground that while this class of cases is still unfamiliar, the name helps to fix some of their important peculiarities in the mind of the profession.

He recognized that some of the cases described could not be mistaken for true locomotor ataxia, but said that they were, nevertheless, closely related to other cases which might be so mistaken.

FOREIGN BODY IN WHARTON'S DUCT.

DR. A. T. CABOT showed a piece of brown straw, one inch and one line in length, and as large as a No. 5 needle, which had lodged for six months in Wharton's duct.

The patient, a young man, lost a piece of straw under his tongue on the 14th of May, 1887. For three or four weeks he experienced no trouble from it. Then a somewhat painful swelling of the submaxillary gland upon that side occurred.

When seen in August, the submaxillary gland contained a hard swelling about the size of a robin's egg, and in the line of the duct, about one inch from its orifice was a little hard swelling as large as an apple seed. Pressure along the duct caused the issue of a drop or two of pus. The bit of straw being supposed to be very small and evidently lodged far back towards the gland, a cutting operation in search of it seemed unadvisable, and the patient was advised to press occasionally over the gland, and then along the duct so as to force the pus and secretion out, in the hope of working the straw out along with it.

This milking the gland and duct was followed by a decided increase of pain and swelling, but it was continued at intervals until October 1. At this time a little abscess formed over the duct, and was punctured by the patient. A few drops of pus appeared. On November 15th the patient found that when he gaped and raised his tongue, the duct was so shortened that the tip of the straw appeared at the orifice. After some trouble he succeeded in seizing the end with a fine pair of scissors and withdrew the straw.

Poulet, in his exhaustive work on "Foreign Bodies in Surgery," has succeeded in finding but six authenticated cases of foreign bodies in Wharton's duct. In one of these the foreign body was, as in our case, a bit of straw introduced while picking the teeth. A very severe inflammation followed in the case reported by Poulet, and, abscesses forming, the straw, which was

[1] Ibid. Bd. xvii., H. 2.

two-thirds of an inch in length, was finally discharged spontaneously in two pieces.

A careful search in this case at the time of opening the abscesses failed to find the straw.

In answer to a question by Dr. Hooper, Dr. Cabot said that if he had suspected the size of the straw, he should have made an incision of the duct and should have hoped to find it. The evidence at the time he saw the patient, however, was that the bit of straw was extremely small and far back towards the gland where the chances of finding it were but slight. As the patient was suffering no pain, it seemed better therefore to wait and try to work the straw forward to where it could be easily reached. That it was worked forward by the manipulation practised seemed probable by the result.

THE NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, December 1, 1887.

The President, DR. A. JACOBI, announced that the

COMMITTEE ON CONFERENCE WITH THE CITY BOARD OF HEALTH

which he had been requested by the Academy to appoint, in accordance with the suggestion of Dr. Bryant, would consist of the following gentlemen: Drs. C. R. Agnew, R. H. Derby, Stephen Smith, E. G. Janeway, and A. Jacobi.

DR. J. W. STICKLER, of Orange, New Jersey, read a paper on

FOOT AND MOUTH DISEASE AS IT AFFECTS MAN AND ANIMALS, AND ITS RELATIONS TO HUMAN SCARLATINA AS A PROPHYLACTIC.

Having thanked the President for the opportunity of appearing before the Academy, he said that he had two reasons in presenting the paper, the first being that it gave the results of investigations which he had been carrying on for the last four years, and the second, that it pointed out the way in which such results might, perhaps, be turned to practical account. It had long been known that foot and mouth disease may be communicated to the human subject in either of the two ways: *first*, through the agency of milk from affected animals, and, *second*, by the accidental introduction of virus into open wounds. Having referred to the general symptoms of the disease in animals, he mentioned the characteristics which it presented in man, stating that among these were glandular enlargements, vesicles in the mouth and upon the hands and feet, and in some cases, a scarlatinal eruption on different parts of the body. This was the case of Hertwig, and others who purposely contracted the disease by drinking milk from infected animals.

Dr. Stickler then gave some accounts of the sudden and severe epidemic of sore throat which occurred in Dover, England, in 1884, and attacked the inmates of the best houses in the place; and said that it was conclusively proved that the outbreak originated from milk obtained from cows suffering with foot and mouth disease. In the majority of cases the two principal symptoms were inflammatory sore throat and enlarged cervical glands, while in many instances vesicles were also noted. The sequelæ in general resembled those of scarlet fever. An investigation of 182 of the cases, made two years after the outbreak, showed the following points:

(1) None of the patients had since had scarlatina.

(2) Numbers of families who have previously had scarlatina as a rule escaped the epidemic, while those who had not had scarlatina were generally attacked.

(3) Sixteen of the patients have already had scarlatina.

(4) Four of the these were very mild cases.

(5) Two of these had had scarlatina when they were very young.

(6) In ten cases it was doubtful whether the patients had had scarlatina or not.

He then related the histories of three cases in which he inoculated children with virus from milch cows and subsequently exposed them to the contagion of scarlet fever. The first was a child eight years of age who, after it had entirely recovered from the effects of the inoculation, was taken to the bed-side of a scarlet-fever patient, and made to inhale the breath of the latter and place its head upon the pillow used by him. Yet, notwithstanding this exposure, the child did not develop scarlet fever. The second was a child four years of age, in whom the inoculation produced much greater constitutional disturbance, than in the previous instance. The throat and mouth became sore, the temperature went up to 103°, and there was a scarlatinal eruption, followed by desquamation of the cuticle. The child was afterwards directly exposed to the infection of scarlet fever in the same way, and did not contract the disease. The third child inoculated was a boy ten years old, and although during the three years since the inoculation was made, abundant opportunities for infection had been met with by him, up to the present time he had escaped scarlet fever. Dr. Stickler said that he was well aware, however, that at this stage of the investigation now being made no positive conclusions in regard to the prophylaxis of scarlatina could be arrived at.

While foot and mouth disease was essentially the same in man as in animals, there were seme points of difference, and he now proceeded to describe in detail the symptoms met with in the latter. There were four marked stages in its clinical history in animals, viz.: (1) fever; (2) eruption; (3) desiccation, and (4) desquamation. In milch cows the flow of milk became nearly suppressed, while the milk was of a yellow color and readily coagulated on boiling or when exposed to even a moderate degree of heat. There were vesicles in the mouth and throat, and unhealthy ulcers and erosions were sometimes left. Thomas had stated that scarlet fever was the only disease in which the mucous membrane could be torn away in considerable pieces, but he was not probably aware that this was also the case in foot and mouth disease. Repeated attacks of the affection in the same subject were supposed to be rare; but authorities differed very greatly in regard to this point.

Klein, he went on to say, had discussed what he believed to be the germ of foot and mouth disease, and stated that it could not be distinguished from the germ met with in the disease, caused by milk, which occurred at Hendon, and was unquestionably scarlatina. In order to test the transmissibility of scarlet fever from man to the lower animals, Dr. Stickler inoculated two colts by injecting virus into the jugular vein and also giving them saliva and mucus from the mouth and throats of scarlet-fever patients, to swal-

low. In one colt the temperature went up to 103°, and in both there were sore throat, redness of the mucous membrane, cough and difficulty of deglutition. In one of the cases there also resulted desquamation. Having repeated these experiments in a large number of other animals, he was convinced that it was possible to inoculate the lower animals with scarlatina.

In inoculating human beings with virus from animals thus treated, the lesion was found to be a mild one, and he believed that this virus could be used in such a way as to prevent scarlet fever, subsequently, four years ago he had inoculated twelve cases in this way with good results. Out of thirteen other children inoculated, who were already exposed to the infection of scarlet fever at the time, five escaped the disease entirely; while eight were attacked with it. None of these cases, however, were severe, and the question arose whether the severity of the disease had not been mitigated by the inoculation. During the last year he had inoculated two children. In conclusion, he said, that while it was by no means proven that scarlatina could be prevented by such inoculations, the results thus far obtained were very suggestive, and he hoped to pursue still further the investigations in which he was engaged.

DISCUSSION.

DR. ANDREW H. SMITH said that the author of the paper had certainly made out a very excellent case for the efficacy of inoculations against scarlet fever. He would like to inquire whether it was an easy matter to procure virus, so that the supply could be kept up in case the method came into general requisition.

DR. STICKLER replied that the foot and mouth disease was extremely common in Europe. In this country, however, it was very rare. There had been an attack of it in Maine two years ago, and he had also been told that it had occurred in the West. The disease which affected the cows at Hendon was not so frequent. This he believed to have been genuine scarlet fever, and he thought there would never be any difficulty in inoculating milch cows with scarlatinal virus derived from the human subject.

DR. SMITH said that he feared that if virus derived from cows inoculated in the manner suggested by Dr. Stickler were employed, the children thus treated would be subject to all the dangers of the unmodified disease, as was the case in small-pox, when the latter was transmitted from person to person by inoculation.

DR. FINLAY, a veterinary, said that he had seen a great deal of foot and mouth disease in Scotland. It was regarded as an epizootic aphtha, and one attack of it conferred no immunity whatever from subsequent attacks, as he had known cattle to suffer again from the disease within six months after having had it, and it was exceedingly common for the same animals to have it more than once. In the case of sheep, however, it really seemed that one attack was protection against subsequent ones, and he did not remember ever to have seen a recurrence of the disease in the ovine tribe.

A physician who was the medical attendant of one of the children inoculated by Dr. Stickler said that he had never seen a case of scarlatina more marked than that following the inoculation. The child was perfectly healthy at the time the inoculation was made. There was at first a slight blush around the seat of inoculation, and when this subsided the patient was entirely well. Then followed a distinct attack of scarlatina, the temperature running up to 102½° or 103°, and the eruption becoming general. On the sixth day desquamation commenced. So far as he was aware the child had not been exposed to scarlatina in the ordinary way, although the disease was more or less prevalent in the school district in which it lived, and it was possible that it might have been so exposed. The point of interest was that the case presented all the characteristic signs of true scarlatina.

PROFESSOR LAW, of Cornell University, said that as regards the prophylactic form of foot and mouth disease against scarlet fever in the human subject he had to confess that he was still a skeptic. In Great Britain there were frequent outbreaks of the disease, which affected not only the cattle but the people coming in contact with them, and he thought that if foot and mouth disease prevented scarlatina, the latter ought to be a much less common disease there than in this country, where epizootic aphtha was almost unknown. Such was not the case, however, as the statistics show that during the last five years no less than ninety thousand deaths in Great Britain had been due to scarlatina. Then, again, an attack of foot and mouth disease conferred a very limited, if any, immunity from subsequent attacks, and, like Dr. Finlay, he had known it to recur within six months in the same animal. Recurrence of the disease was very common in his experience, and he would, therefore, hardly suppose that inoculation with it would confer immunity from scarlatina for any length of time, if at all. While it was a very contagious disease when there was direct exposure to it, he believed that it differed from scarlatina as to its contagiousness under other circumstances. His own personal experience also tended to throw doubt upon Dr. Stickler's hypothesis. While he had been over and over again exposed to any amount of morbid products from cases of foot and mouth disease, he had never suffered from the affection, but the very first time that he was exposed to the infection of scarlatina he contracted that; his system being susceptible to the one, but not to the other. These points, therefore, seemed to militate against the protectiveness of one disease against the other. Still, it did not follow that the immunity conferred by foot and mouth disease might not be more extended in a race less susceptible to its influence than the bovine.

As regards foot and mouth disease he would strongly urge that the investigation into its prophylactic power should be carried on on the other side of the Atlantic, as it would be a very serious matter if that affection should be introduced in this way among American cattle, and he had no doubt that there would be a general outcry among the cattlemen if it were known that experiments were being made with the virus of the disease in this country.

Again, if we employed the virus of scarlatina for making inoculations, did we not more widely disseminate the disease? While he had great respect for the ability and achievements of Pasteur, he could not but believe that he had increased the spread of anthrax by scattering broadcast his modified anthrax virus, for he was convinced that a weakened virus might, under certain conditions, be rendered potent and dangerous. In the same way he feared that rabies would only be increased by the dissemination of his attenuated virus of that disease, and he believed

it to be a fact that there had been more rabies among dogs in England since the discovery of Pasteur than ever before. These considerations, in his opinion, condemned the method, and he thought that the living germ of the same disease ought never to be used for inoculations on account of the danger of spreading the affection involved.

Dr. McLean, a veterinary, said that he did not doubt that the Hendon epidemic was one of true scarlatina, but he thought it had by no means been proven that the scarlatina came from the cows. He denied that there was such a disease as bovine scarlatina, except, possibly, in cases where the disease was transmitted directly from the human subject by inoculation. In the Hendon outbreak the disease might have been conveyed by the milk, but if this was the case it did not come originally from the cows. The milk was no doubt contaminated from other sources, as had frequently been noticed in epidemics of typhoid fever and other affections, and it was well known how excellent a medium milk was for the conveyance of infectious diseases.

Again, he did not think it susceptible of proof that foot and mouth diseases was prophylactic of scarlatina, as he believed this to be a specific disease, the germ of which was capable of giving rise to epizootic aphtha, and to nothing else. So far as he was aware there had been but two outbreaks of foot and mouth disease in this country, one in Maine and the other in the vicinity of New York city, extending up the Hudson as far as Poughkeepsie.

Dr. John C. Peters said that a great many of the most eminent veterinary authorities believed in the occurrence of scarlatina in horses and cattle.

Professor Law said that veterinarians had unfortunately given the name scarlatina to an affection in which there was redness of the mouth, but which was non-contagious and totally distinct in character from true scarlet fever. The name had consequently given rise to much confusion.

Dr. J. Lewis Smith said: Since the time of Jenner the hope has been awakened that some of the other fatal infectious diseases, and especially scarlet fever, might be prevented as small-pox has been, by the substitution of a milder and modified disease, derived from the lower animals. As regards scarlet fever two propositions of great interest and importance have arisen: First, is there a disease in the bovine race which is a true scarlet fever, or which communicates genuine scarlet fever to man, and secondly, if there be such a disease, does it produce a mild and modified form of scarlet fever in man.

Many instances have been recorded in the last five or six years, in which epidemics of scarlet fever have arisen from the use of milk furnished by healthy cows and infected with the scarlatinous germ after the milking, but in the St. Marylebone and Hendon epidemic, occurring two years ago and described in the *British Medical Journal*, May 20, 1886, the outbreak of scarlet fever appeared to be clearly traced to diseased cows. Now the point to which I wish to call attention is this. The sickness of the cows was mild, not appreciably impairing their appetite, nor diminishing their milk, but the disease which the use of the infected milk produced is described as an "intense outbreak of scarlet fever." Instead of a mild disease being propagated from the cow, for which we are looking and hoping, the reverse occurred. A mild form of the disease in the cow produced a severe one in man, so that it appears from the history of this epidemic that by inoculating with the bovine scarlatinous virus, we might produce severe and fatal epidemics, instead of a mild and modified form of the disease.

Dr. Stickler, in closing the discussion, said that if he produced only a slight and harmless attack of scarlatina by his inoculations he could see no objection to the use of the scarlatinal virus for this purpose. and when the terrible effects of the unmodified disease were taken into consideration, he thought it of extreme importance that a method of protection should be secured, if possible. As to the disease from which the Hendon cows suffered, it had, he thought, been clearly demonstrated that it was nothing else than scarlatina, since it was precisely the same affection as was ordinarily produced in cows by the inoculation of scarlatinal virus from the human subject.

Recent Literature.

Transactions of the Association of American Physicians. Second Session. Held at Washington, D. C., June 2d and 3d, 1887. Philadelphia: Printed for the Association. 1887.

The second volume of the transactions of this Association is issued with commendable promptness and in a most attractive typographical dress. It contains two hundred and fifty pages. The articles, seventeen in number, comprise: Hepatic Cirrhosis in Children, by Professor R. H. Howard, of Montreal; Direct Functional Murmurs and Obstructive Safety-valve Action in the Heart, by Dr. John Guiteras, of Charleston, S. C.; Pneumatic Differentiation, by Dr. H. A. Johnson, of Chicago; Methods of Research in Medical Literature, by Dr. John S. Billings, U. S. A. Two papers on Antipyretics in Fever, by Drs. H. C. Wood and Francis Minot; Sewer-gas Poisoning, by Dr. Henry Hun, of Albany; Aneurism of the Abdominal Aorta, by Dr. Israel T. Dana, of Portland. Two papers on Hæmorrhagic Infarction, by Dr. Wm. H. Welch, of Baltimore, and Wm. Osler, of Philadelphia; Atrophy of the Gastric Tubules, by Dr. F. P. Kinnicutt, of New York; a third contribution to the study of Localized Cerebral Lesions, by Dr. E. C. Seguin, of New York; Forms of Typhoid Fever simulating Remittent Malarial Fever, by Dr. I. E. Atkinson, of Baltimore; The Frequency with which Lead is found in the Urine, by Dr. J. J. Putnam, of Boston; the "Bergeon" Treatment of Pulmonary Diseases is discussed by three writers: Drs. E. T. Bruen, F. C. Shattuck, and Wm. Pepper, none of whom found any considerable advantage to have been derived from the gaseous injections.

The readers of the Journal have already been given some half-a-dozen of these papers in full, and from their quality may fairly judge of the standard of the contributions of this young and vigorous Association.

— A London druggist has hit the popular taste for good bargains. In his window he displays a card that reads: "Come in and get twelve emetics for one shilling."—*Texas Siftings.*

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 22, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

STOGDALE *vs.* BAKER.

FOUR times in as many years Mrs. Annie Stogdale has come into court with her faithful legal advisor and has related to the twelve men on the jury and to such other men as chose to listen, the story of her alleged wrongs at the hands of Dr. W. H. Baker, and has asked that he be compelled to pay to her the sum of ten thousand dollars as a placebo for gynæcological malpractice and its consequences; telling her auditors with unaffected plainness all about the manner in which she was drugged and abused and made to lose her ovaries under false pretences at the Boston Free Hospital for Women, and forced to go through life unsexed, and with an unsightly hernia at the cicatrix of the opening through which the rape of her sexual glands was accomplished. Four times has she sat by with ingenuous unconcern while, for the defence, the jury was enlightened concerning the mysteries of her pelvic anatomy, physiology and pathology, in all their details. Four times has she, under oath, denied her own signature upon a document prepared before the operation for the removal of her ovaries, and giving her full and free consent to that procedure. Four times has her singular compound of facts, fancies, and falsehoods been met and controverted by clear evidence, and her counsel's theory of the medical aspects of the operation itself and its needlessness has been exploded by able expert testimony. And now, at the end of the fourth wearisome trial, a jury has agreed in deciding a question upon which its three predecessors declared their inability to agree, and has formally rendered its verdict that Dr. Baker is wholly free from the blame imputed to him by this misguided woman and the erratic people who, under the impulse of a misdirected philanthropy have given her their money and their sympathy.

The JOURNAL extends its congratulations to the defendant in this case that he has at length secured this personal vindication. We congratulate and thank him in a larger sense that, loyal to his profession, conscious of his rectitude, tenacious of his rights, he resisted all inducements to compromise the affair by settlement, and met the issue squarely and fearlessly as often as his persistent adversary, longing for lucre, chose to raise it.

This example of endurance to the end should not be forgotten or unheeded by the medical profession. The settlement of suits for malpractice by the payment of money to avoid a trial is relatively economical, and is attended with the least degree of vexation and anxiety; but it is precisely the issue which unscrupulous lawyers, representing impecunious claimants, hail with satisfaction, and the direct tendency of such a course is to make the terms of the settlement increasingly exacting and more and more of the nature of blackmail. Therefore, when a defendant in a suit like the present one carries his case through to a verdict by a jury and wins his cause, he does much more than any other method can accomplish to discourage shyster lawyers and unprincipled claimants from bringing fraudulent suits.

One feature of this trial deserves special mention. Before entering upon the examination of witnesses the counsel for the defence moved, and the court granted the motion, that the plaintiff should file a bond, with proper securities, for the payment of all the costs of the suit, in the four trials, if in this trial the jury rendered a verdict for the defendant.

This proceeding is very unusual in the courts of Massachusetts; but it is plainly a very just and commendable one. We wish it might become a rule of universal application in actions of tort. It would be a distinct and effectual hindrance to unjust suits which are little else than blackmail in their motive. To the objection that poor but deserving plaintiffs would thus be placed under a serious if not controlling disadvantage, the answer is that if the counsel really believe in the justice and soundness of their client's cause, and are willing to assume the risk of a trial in other than a spirit of speculation, they can find at any time an easy way to meet this preliminary obstacle, and the discretion of the court may safely be trusted in fixing the conditions of the bond with equity.

Another thought is suggested by this remarkable series of trials. Ought not medical men to combine to protect themselves from the ever-impending risk of actions for malpractice, and to defend themselves successfully when such actions are brought? These litigations are expensive to the defendants in time, money and anxiety, and there are few who are disposed or can afford to engage in defending a suit if an easy and honorable way of avoiding it is afforded. But in unison there is strength; and if surgeons, obstetricians and all other medical men who love their profession, and recognize its true relation to the law, would join in a mutual association for medical defence, pledging themselves to pay assessments for the legitimate expenses of the best possible defence of any of their number unjustly charged with malpractice, we should hear less of trial by jury with physicians as

defendants. Such an association, by its very existence, would deter lawyers from bringing shaky suits into court, and it might become a power in securing legislation to the same end.

THE NERVE-REST CURE.

Under this head, James Muir Howe, in the last *Nineteenth Century*, discusses the Weir Mitchell treatment of nervous diseases.

Nervous subjects, says this writer, are generally regarded by doctors as most unsatisfactory patients. No sooner do they find such an one than they order him off to the mountains, or over the seas, anywhere to get rid of the trouble of treating him. Some affect to believe that nervous subjects feign their ailments for the purpose of attracting attention and sympathy. It is quite true, says Mr. Howe, that they frequently exaggerate their sufferings, but that is no reason for denying their existence. Nervous irritability is described as insanity of the nerves, and it is certainly quite as deserving of recognition and treatment as insanity of the brain. He whose brain is insane is generally oblivious of the opinion of his fellows, while he of insane nerves is usually acutely conscious of want of sympathy on the part of his friends. A harsh word or an unfriendly glance will worry him as much as a heavy loss. Indeed, many such sufferers are driven to drunkenness through dread of the daily annoyances of daily life.

The writer gives several instances in which strong mental control on the part of the patient has put a stop to perverted functional nervous action. Of these, we give one: A young lady in other respects healthy, had gastric nerves so wayward that they would allow only a very small amount of food to remain on the stomach. This condition produced both debility and inconvenience. Her physician told her that she might, by a strong mental effort free herself from the ailment. She tried her best, but failed. It became apparent that she did not possess sufficient will-power for the task. The physician decided to assist the will by inducing a strong emotion with respect to the ailment, and this he effected in the following manner: Going to the future husband of the lady he urged him to inform her that their union could not take place until she was cured. The time fixed for the marriage was near at hand, and the shock of such news had an immediately beneficial effect. The gastric nerves began to resume their normal functions from the moment of that interview.

Cases in which such treatment is beneficial are very rare. Even when successful in abolishing the ailment, it may prove highly injurious to the patient, who thus strains one set of nerves to control another, for if the higher nerves are not much stronger than the lower, general nervous prostration will ultimately supervene. Many local nerve affections carry off irritation from the nerve centres, just as an attack of gout in the great toe frequently relieves an irritable brain. It is therefore dangerous to suppress a local symptom without previously removing any existing central disease. In the case just related, the central nervous system was healthy, consequently no harm resulted from suppressing the local symptoms.

Mr. Howe comes to the rational conclusion that the safest way to cure the majority of nervous affections, is by means of nerve-rest to reduce the general nervous excitability of the patient. It is highly injudicious to urge a nervously exhausted person to exertion before he has had rest sufficient to enable him to lay up a fresh store of nervous energy. Under the forcing system, one patient walked herself almost into a lunatic asylum to ward off a threatened attack of hysterical paralysis. This is an instance of the lower nerves being controlled by the higher to the detriment of the latter. It was ultimately decided to prohibit walking in this case, the power of reason being considered of more importance than that of locomotion.

The writer further dilates on the great advantage which has accrued to the therapeutics of nerve maladies by the systematic rest inaugurated by Dr. Weir Mitchell. Nerve reparation gradually but surely follows. The muscles by frequent passive exercise with massage and electricity, are braced up and kept from wasting, and thus are able to respond to the call of the renewed nerves.

Moreover, the passive exercises to which these patients are subjected, promotes general nutrition and enables the patients to tolerate the persistent overfeeding, which is a part of the treatment. The amount of exercise undergone in massage equals a walk of several miles daily, so that there is more appetite in two hours, than there used to be after a whole day's fast.

The treatment indicated is in a measure applicable to the minor degrees of nervous exhaustion. For one who cannot get a sufficient holiday, the best substitute is an occasional day in bed. Many whose nerves are constantly strained in their daily vocation, have found this out for themselves. A Spanish merchant in Barcelona told the writer of the review article that he always went to bed for two or three days whenever he could be spared from his business, and he laughed at those who spent their holidays on toilsome mountains. If we cannot avoid frequent agitation, we ought, says Mr. Howe, to give the nervous system time to recover itself between the shocks. "Even an hour's seclusion after a good lunch, will deprive a hurried, anxious day of much of its injury. The nerves can often be overcome by stratagem when they refuse to be controlled by strength of will."

FREQUENCY OF TWIN AND TRIPLET BIRTHS.

Medical statistics, have a certain value, either as pertaining to the beginning, the duration, or the close of life. It does not follow that, because a city or a country practitioner has met two or three cases of trichinosis, or of fracture of the os calcis, or any other

rare disease or surgical lesion, upon a single street, within the same week, the same event will occur to him on the following week. One or two deaths only from the first mentioned cause have occurred in Massachusetts in the past twenty years.

The probable error in computation from small, is vastly greater than that from large numbers. The obstetrician occasionally writes to know the ratio of twin or triplet births to 1,000, 10,000, or more labors. Other things being equal, such as race, climate, character of population, etc, the variation between any two series of one thousand labors, will usually be greater than the variation between two series of ten thousand labors.

We have in the Massachusetts Registration Reports, an opportunity to study the ratio in one million births. In the twenty-five years ending with 1886, there were registered in Massachusetts, 1,016,278 births. There were also registered in the same time 9,028 pairs of twins, and 109 cases of triplets. This gives a ratio of one case of twins in every 113 labors, and one case of triplets in 9324 labors. So that the common statement that one case of twins occurs in 100 labors, and one of triplets in each 10,000 labors is not far from correct.

In the period named, the greatest frequency of twins in any year was in 1865, when there was one case registered in 96 births, and the least frequency was in 1885 when there was one case of twins in 130 births. In 1881 there were registered nine cases of triplets, or one in 5024 births and in 1879, but one case in 40,205 births.

As an instance of marked departure from the above, and also an illustration of the error in dealing with small numbers, two cases of triplets occurred in the writer's practice in a series of less than 300 labors.

ANNUAL REPORT OF THE MARINE HOSPITAL SERVICE.

THE report of the supervising Surgeon-General of the Marine Hospital Service shows that the number of sick and disabled seamen to whom relief has been furnished during the past year is greater than any preceding year since the organization of the service. The chief part of the report proper is occupied with material relating to quarantine, the yellow fever epidemic at Key West, and kindred matters. The appended tables are numerous and full. Among them is a statement of the mortality of passengers on voyages from foreign ports to the United States for the year preceding June 30, 1887.

A large number of pages are devoted to selected cases from hospital practice, and records of autopsies. The cases show a very large amount of surgery done during the year. The radical cure of hernia is given considerable prominence in the service evidently. The table of operations shows that eleven cases were operated upon, with one death. Six of these cases are given at length, but the fatal case is not among them.

THE DISCUSSION ON THE CANCER BACILLUS BEFORE THE BERLIN MEDICAL SOCIETY.

THE scientific men at the Society of Internal Medicine of Berlin, Session 28th of November, who discussed Scheurlen's claims to the finding of the cancer bacillus, with one exception, were not disposed to make much account of Scheurlen's alleged discovery. Fraenkel thought Scheurlen's culture methods defective. It is a little singular that the bacillus which the latter thinks to be the *vera causa*, should proliferate so rapidly in the culture media, and in almost all nutrient media, while in tumors it multiplies so slowly; for cancerous growths are notoriously of slow development. It is, remarked Fraenkel, a matter of experience that a bacillus which multiplies with rapidity in most culture media, also multiplies equally fast when it is of pathogenic nature. But this, as before said, does not agree with the slow development of cancer.

Moreover, from all that we know of the action of the pathogenic schizomycetes we never find them giving rise to epithelial products. The bacilli develop only in the blood or in the connective tissue where there are blood vessels and lymphatics; and when they provoke processes of proliferation as, for example, in cases of tuberculosis, lepra and syphilis, we always witness the development of typical products, as the granlomata of Virchow, but we never observe an epithelial proliferation.

Fraenkel thought that Scheurlen had not taken sufficient pains to exclude the possibility of a variety of bacteria in the case given with which he originated his cultures. This can only be done by a process like Koch's "fractional" method, which would require first diluting with water or liquified gelatine the cancer juice, then "sowing" it in a suitable medium, and on glass slides from which the air is excluded, watching the development of spores. In this way pure cultivations might be obtained, and it could easily be perceived whether there were present several distinct species or only one. Fraenkel was disposed to admit that carcinomata belonging, as they do, to tumors that are the subjects of rapid degeneration, either caseous or fatty, are likely to be the prey of numerous kinds of schizomycetes, which penetrate them from the exterior. In other words, secondary infections might easily occur. He believed cancer to be an infectious disease, but was not clear that it was of bacillary origin.

At the same meeting, Guttmann expressed his satisfaction with the results obtained by Scheurlen, and read a letter from Dr. Schill, of Dresden, in which the latter, who has been for the past five years seeking for the microbe of cancer, states that he has discovered a bacillus resembling that described by Dr. Scheurlen.

MEDICAL NOTES.

— The Emperor of Brazil has had glycosuria for five or six years, and the symptoms have lately become worse.

— Press reports from Selma, Ala., state that a horrible murder was committed there on December 18th by W. W. Jordan, a crazy faith-doctor. He had been living in Selma for the past twelve months, and had in that time acquired great influence over the negroes, whom he told that he had come to redeem the Jews. He arranged for a passover-feast at the house of two negro women on the outskirts of the city, and told them that a sacrifice was necessary. One said that she was willing to offer herself, and laid her head on the table. Jordan thereupon took a sword and struck her several blows on the neck and stabbed her a number of times, killing her instantly. The body was then dragged out into the street by the two other women.

— The Medical Society of the County of Kings, New York, has authorized the publication of a monthly medical journal, to be known as the *Brooklyn Medical Journal*, to contain the transactions of each meeting, together with the papers read, and the discussions thereon. It is to be edited by five members of the society, appointed by and under the control of the council. It is expected that it will contain the transactions and papers of the Pathological, the Surgical, the Medical, Microscopical, the Pharmaceutical, and the Dental Societies.

BOSTON.

— The Boston Cremation Society has failed to raise the capital stock of $25,000 requisite to erect its buildings; only about $7,000 were subscribed, and this sum is to be returned to the subscribers, who are referred to the Massachusetts Society of similar aims.

NEW YORK.

— The Methodist Episcopal Hospital, of Brooklyn, which was formally opened last week, is an imposing structure, consisting of three separate buildings of brick, trimmed with freestone, occupying an elevated site just west of Prospect Park, which covers an entire city block. The grounds are rectangular, extending about seven hundred feet east and west, and two hundred feet north and south, and include more than three acres. The main building and the two pavilions, one on either side of it, are connected only by light corridors on the ground floor. Mr. George I. Seney, the founder of the hospital, has given in all $410,000 towards its erection and equipment, his only stipulation being that the institution should be open to individuals of all creeds alike. In addition to this amount, $70,000 has been raised from other sources; but a considerable sum is still needed to fully complete the buildings, when there will be accommodations for two hundred patients. Among the speakers at the dedication ceremonies was Dr. Horatio C. Wood, of Philadelphia.

— The Board of Estimate and Apportionment have fixed the appropriation for the expenses of the Board of Health for the year 1888 at $394,287.

— In order to get some more effective check upon bad plumbing than at present exists, President Bayles, of the City Board of Health, has secured from the Corporation Counsel an opinion that it lies with the Department of Public Works to refuse a permit to connect with the Croton water mains any building in which the plumbing is condemned as illegal by the Health Board.

— For the Christmas dinners of the inmates of the various institutions under the charge of the Department of Charities and Correction 12,990 pounds of chicken, and 3,445 pounds of turkey will be required. The Insane Asylum on Ward's Island receives the largest amount of poultry of any one institution, on account of its more numerous population, 1,850 pounds of chicken, and 500 pounds of turkey.

Miscellany.

THE CONVERSION OF BENIGN GROWTHS OF THE LARYNX INTO MALIGNANT.

AT the recent Congress of German Naturalists and Physicians, Professor Schnitzler read a paper upon the subject of the "Malignant Degeneration of Benign Growths in the Larynx." He first described, as we learn from the *Lancet*, a case of epithelial carcinoma with secondary growths in the lymphatic glands and pleura, in a patient who some months previously had been operated on for papillomata, the recurrence of which had been treated by cauterization. The patient subsequently came under Professor Schnitzler's care with symptoms of perichondritis, but the carcinomatous nature of the disease was recognized, and the supervention of pleurisy some weeks later was considered to be due to a diffusion of the malignant disease. This diagnosis was confirmed after death, when, besides the laryngeal and pleural carcinoma, there were found necrosis of the thyroid cartilage and gangrene of the right lung. Professor Schnitzler remarked upon the rarity with which benign tumors take on malignant characters, he having seen such conversion only three times among hundreds of cases of laryngeal papillomata. He left undetermined the question whether the operations and frequent cauterizations induced the malignant disease, and said that endo-laryngeal operations upon papillomata should be discountenanced on this ground. He also spoke of the difficulty in the differential diagnosis between benign and malignant growths, as well as between laryngeal syphilis and carcinoma. Dr. Morelli related the case of a man whose larynx was so blocked by papillomatous growths as to necessitate tracheotomy prior to a thyrotomy with complete ablation of the new growth and galvano-cauterization of the laryngeal wound. The patient left apparently cured, but wearing the tube. After the lapse of a year, he returned with evident carcinomatous degeneration of the papilloma, which filled the larynx to the level of the tube, which was partially displaced and blocked by it. This was the only case of the kind that Dr. Morelli could recall within a period of nearly ten years. Dr. Seifert referred to a case published by Böhmer, where papillomata (histologically examined) had been treated by Professor Gerhardt and himself for a year, but which passed into carcinoma, for which the extirpation of the larynx was practised; but the patient did not long survive the operation.

Correspondence.

HEBRA'S CURE FOR DYSPEPSIA.

VIENNA, AUSTRIA, December 5, 1887.

MR. EDITOR,— Not long since I had brought to my knowledge the fact, that Messrs. T. K. Cook & Co., chemists, of New York, are manufacturing and advertising a remedy under the title of "Dr. Hebra's wonderful cure for Dyspepsia."

In justice to myself I wish to say, that in spite of the statement made in their circular, I have never placed the result of any analysis, nor any antidotes against dyspepsia in Messrs. Cook & Co.'s hands. Further, that I have given them no right to use my name and that they are not authorized in any way whatever to sell the remedy under the title used.

The great distance of my residence from New York renders it difficult, if not impossible for me to prosecute Messrs. T. K. Cook & Co. for the misuse of my name, so that I can not do better than to warn the public through your columns against a remedy which has been offered to it in fraudulent guise.

If you will kindly publish this letter you will greatly oblige, Yours very truly, DR. HEBRA.

ANOTHER EPITAPH.

BOSTON, December 17, 1887.

MR. EDITOR,— In your last issue you gave an epitaph of a London dentist. This one, evidently suggested by her physician, a distant relative of mine, found on a gravestone in a cemetery, Surrey County, England, may amuse your readers.

"Here lyes Elizabeth
Betsy Ogden,
1674.
Her lyved no longer
Cos her —— cooden."

Yours truly, WILLIAM M. OGDEN, M.D.

LETTER FROM BERLIN. — SCHEURLEN'S CANCER BACILLUS.

BERLIN, December 4, 1887.

MR. EDITOR, — Those who watched the painful fœtal development, birth and growth of the Bacillus Tuberculosis, and of the Coccus of Erysipelas, will not be surprised that the Bacillus of Cancer is suffering parturition throes quite as tormenting. Every time a new pathogenic germ is heralded, the mass of unlucky bacteriologists, who have no concern in it, rise up to strangle it before fully born. Six years ago the sages of pathology predicted its coming, basing their opinion upon a logical balancing of anomalous instances. Every student who has watched with becoming intelligence the march of science, who has seen the old landmarks of ætiology and pathology levelling themselves and giving place to established facts, who has noticed how one well established discovery led up to another, and how probable the deduction was that anomalous forms of disease might be due to similar causes, will not now be astonished that Scheurlen has announced a new bacillus. Fränkel's arraignment, to those who can read between the lines, amounts to nothing as scientific argument. S. Guttmann and Stabsartz Schill both confirm the results after personal experimentation and investigation. Schill has been for years engaged in the same line of inquiry. Not in one instance nor in two did Scheurlen find these bacilli, but in every case examined by him. Because Koch was not fortunate in finding it, this has no bearing whatever upon the question; neither did he find the coccus of erysipelas, but yet no one to-day doubts Fehleisen's work. If it be true that certain eminent doctors in New York have travestied this matter, as the telegrams of yesterday report, it only lowers them as scientists in the eyes of those competent to judge, and presupposes a snap judgment of a subject which they have never investigated, and concerning which, consequently, they are incompetent to pass an opinion. There is a bacillus of cancer just as really and absolutely as there is one of consumption. Its morphological characteristics are not yet clearly defined, and there are many other doubts to clear up and questions to answer. But all of this can come only after many months of hard and patient labor. It stands exactly upon the same ground that the coccus of erysipelas possessed when announced, and it will possibly go through the same fiery ordeal that all original work must go through before accepted. To be a competent critic there are certain well-recognized prequisites: (1) A man must be thoroughly well trained himself in habits of research, and especially in those lines of inquiry related to the subject in hand. (2) He must come to his work free from any preconceived ideas that would warp his judgment, and free from personal feeling which would belittle his learning.

To those who know the inns and outs of professional feeling in Berlin the fact that the discovery was made in Leyden's clinic and not elsewhere is not without significance. Very truly yours,

HORATIO R. BIGELOW, M.D.

"CŒLEBS," "BENEDICK" AND "GAMBOGE."

CRANBERRY CENTRE, December 19, 1887.

MR. EDITOR,— The letters printed in the last two issues of your highly esteemed weekly, from Cœlebs and Benedick have interested me considerably. They bring up old times again. I knew Gamboge well enough, and recollect perfectly well how he first came to get that instrument Benedick mentioned. It was this way: Along about '54 or '55, there was an old maid from Boston, Mass., came to board for the summer at the Meadows. She was a curious sort of a critter — sort of high-strung, and *called herself* thirty-five and an invalid. I can see her now a teetering along the main street, with a hoop-skirt as big as a hay-stack. The folks where she boarded used to be (*and are still*), patients of mine; so when she began asking about a doctor, they told her "that I was, etc." But she said I lived too far away, and as she often needed medical attendance in a hurry, she couldn't think of depending on a man living four miles off — so Gamboge got the case and a circus it proved. Every morning she was as chipper as a lark, full of talk "about Shakespeare and the musical glasses," as an old aunt of mine used to say, but when Gamboge had got well tucked in for the night, she would yank him out of bed, and when he got there she'd have lost her voice and make signs to him that something had come up from her lower splanchnic cavity and was choking her to death. Of course, if she had been a native, he would very soon have tried what cold water and mist. assafœd. could do toward- making her let his night-bell alone. But the fact was, she sort of topped it over him with her city airs and her talk about Ossian's poems and the Waverley novels, and then again, next morning when he entered his $1.50 on his books (the regular charge to the natives at that time, for a night visit being only 75 cents) he'd feel somewhat consoled for his broken sleep. He dosed her well (always gave *medicine* enough), with valerian, elixir pro., etc., but nothing seemed to hit the case until she explained to him that hers was a case of "reflex nervous trouble of internal origin," and Gamboge felt obliged to buy the speculum which amuses Benedick so much; this, though "old-fashioned" in style now, answered its purpose very well until one fine morning the patient took the early stage for Boston, *forgetting his bill*. The way the doctor swore was terrible.

The "presence of older women" and the "sheet" seems to amuse Benedick very much. The least he has to say on that subject the better, Gamboge with all his faults was an *honorable*, *clean* and *decent* practitioner, and did not feel called upon to carry round a bag full of new-fangled speculums on his daily visits, rattling his nonsensical instruments, nor did he think, as some of the young men now-a-days seem to do, that there is a "pessary" which suits

every case, and that a cotton tampon is needed to cure everything in a woman.

I remember that case published in '46, very well, the hemlock decoction was such a "success" that when I ligated those hæmorrhoids the next spring, they seemed tougher than piles usually are. I never published my part of the case, at least *not in print*.

Now about those two young men who settled at the Meadows last year: Living as I do, four miles off, and having arrived at an age when people are not apt to fly off the handle, I can freely say without (I should hope) being called prejudiced, that I don't approve of either of them. Benedick rides up and down the turnpike as if Satan himself was after him; while Cœlebs sits at his office windows, rolling little paper cigars. "Feathers and Lead" I call them, when I happen to talk about them to folks who like a joke.

Benedick "scores a point," as he calls it, by making that spavined mare for which he gave his note last month, haul him over here to the Centre once or twice a day, (I believe he *does* doctor a black woman who lives over by the mill-pond), while Cœlebs, who has traded his horse for some old books, just keeps his chair down, and thinks the geese will come without dough. Cœlebs seems to feel sure, and Benedick possibly believes, that Mrs. B. is going to be a great help to his practice. *May be.* But I have been in physic over forty years, and I never yet knew a woman alone to make a man. Yours respectfully,

FULLER WORMWOOD, M.D.

[We must beg to decline future correspondence on this subject of the "Doctor's Wife." An exception, however, would be made in favor of Mrs. Benedick, should she see fit to address the JOURNAL. *Place aux dames.* ED.]

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 10, 1887.

Deaths reported 1,956: under five years of age 665; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 333, acute lung diseases 300, consumption 235, diphtheria and croup, 143, typhoid fever 53, scarlet fever 47, diarrhœal diseases 25, malarial fever 19, puerperal fever 11, cerebro-spinal meningitis 11, erysipelas nine, whooping-cough eight, measles six. From diarrhœal diseases, New York and New Orleans six each, Philadelphia, Boston, District of Columbia and Charleston two each, Baltimore, Pittsburgh, Nashville, Fall River and New Bedford one each. From malarial fever, New York eight, Baltimore four, District of Columbia three, New Orleans two, Nashville and Charleston one each. From puerperal fever, Pittsburgh three, District of Columbia two, New York, Philadelphia Baltimore, New Orleans, Milwaukee and Haverhill one each. From cerebro-spinal meningitis, New York and Milwaukee three each, Worcester two, Philadelphia, Fall River and Lawrence one each. From erysipelas New York four, Philadelphia and Boston two each, District of Columbia one. From whooping-cough, New York three, Baltimore two, Philadelphia, Boston and District of Columbia one each. From measles, Baltimore five, District of Columbia and Fitchburg one each.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending November 26th, the death-rate was 23.5. Deaths reported 4,158: infants under one year of age 936; acute diseases of the respiratory organs (London) 560, scarlet fever 126, whooping-cough 115, measles 92, diphtheria 44, fever 44, diarrhœa 41, small-pox (Sheffield 16, London and Bristol one each) 18.

The death-rates ranged from 13.8 in Leicester to 34.4 in Blackburn. Birmingham 25.0; Bradford 25.1; Brighton 19.8; Hull 19.9; Leeds 21.3; Liverpool 24.9; London 23.0; Manchester 26.4; Nottingham 24.0; Sheffield 23.1; Sunderland 17.7.

In Edinburgh 23.8; Glasgow 24.5; Dublin 33.8.

The meteorological record for the week ending December 10, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Dec. 10, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 10, 1887, TO DECEMBER 16, 1887.

STERNBERG, G. M., major and surgeon. Assigned to duty as attending surgeon and examiner of recruits at Baltimore, Md.

CLEARY, P. J. A., major and surgeon. Assigned to duty at Fort Wingate, N. M.

ANDERSON, C. L. G., first lieutenant and assistant surgeon. Assigned to duty at Fort McDowell, Ariz.

TAYLOR, A. W., captain and assistant surgeon. Assigned to duty at Fort Robinson, Neb.

APPEL, A. H., captain and assistant surgeon. Assigned to duty at Camp at Highwood, Ill., relieving assistant surgeon H. O. Perley.

PERLEY, H. O., captain and assistant surgeon. Will rejoin his proper station (Fort Wayne, Mich.) S. O. 285, A. G. O. December 8, 1887.

BANISTER, W. B., first lieutenant and assistant surgeon. Ordered to proceed at once from Fort Lowell, Ariz., to Fort Wingate, N. M., and report to the commanding officer for duty. S. O. 128, Department of the Arizona. December 1, 1887.

CABELL, J. M., first lieutenant and assistant surgeon. Ordered for duty at Fort Niobrara, Neb. S O. 286, A. G. O. December 9, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING DECEMBER 17, 1887.

HUDSON, A., medical inspector. Ordered to the "Trenton."

BATES, N. L., medical inspector. Detached from the "Trenton," and placed on waiting orders.

SOCIETY NOTICES.

NORFOLK DISTRICT MEDICAL SOCIETY. —A meeting for Scientific Improvement will be held at the Hall of the Roxbury City Guards, 67 Warren Street, Roxbury, December 27, 1887, at 7.45 P.M. Communications: I. Asthma and its Treatment by Lobelia, by W. C. B. Fifield, M.D. The discussion will be opened by Dr. H. M. Cutts, with a consideration of other methods of treating asthma. II. Various Influences Affecting Lactation, by A. F. Perry, M.D. The discussion will be opened by Dr. F. W. Vogel. III. Exhibition of Pathological Specimens, by W. P. Bolles, M.D.

S. ALLEN POTTER, M.D., *Secretary.*

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. — The Section for Obstetrics and Gynæcology will meet at 19 Boylston Place, on Wednesday, December 28th, at 7.45 P.M. Business: Election of chairman. Discussion: The Treatment of "Posterior Positions." The discussion will be opened by Dr. C. M. Green and Dr. Edward Reynolds.

GEORGE HAVEN, M.D., *Secretary.*

OBITUARY. ALONZO F. CARR, M.D.

Hon. Alonzo F. Carr, M.D., who died at Goffstown, N. H., December 10th, aged seventy years, was born in Goffstown, and was the son of the late Judge Jesse Carr. He graduated at the Dartmouth Medical College in 1839, and had been in constant practice in his native town ever since. He had served in both branches of the State Legislature. A widow and four sons survive him.

RESOLUTIONS ON THE DEATH OF THE LATE DAVID M. PARKER, M.D.

At the Twentieth Annual Meeting of the American Academy of Dental Science, held in Boston, November 16, 1887, the committee appointed to submit resolutions concerning the death of Dr. David M. Parker, having attended to their duty would report the following:

Resolved, That the American Academy of Dental Science has received with sincere sorrow the intelligence of the decease of our late respected friend and associate, David M. Parker, M.D., of Boston, an Honorary Member and former president of this Society.

Resolved, That by the death of Dr. Parker, the Academy has lost one of its most worthy members, a man of excellent judgment and skill in his profession, and always interested in all movements looking towards the better organization and education of the profession and the advancement of its practice. He was highly esteemed in the community in which he lived, because of his kindly virtues and his earnest, upright and sincere life.

Resolved, That the proceedings of the Academy this day, in honor of our late lamented brother, be engrossed upon the records, and communicated to the widow of the deceased, with the assurance of our deep sympathy in her bereavement. Also, that a copy be transmitted to the *Independent Practitioner*, the *Dental Cosmos*, and the *Boston Medical and Surgical Journal*, for publication.

ELISHA G. TUCKER
JACOB L. WILLIAMS
EDWARD N. HARRIS

DEATH.

Died, at Vineyard Haven, Mass., December —, 1887, John Manchester Smith, M.D., M.M.S.S., aged sixty-one years.

BOOKS AND PAMPHLETS RECEIVED.

Roman Fever. By Gregorio Fedeli, M.D., of Rome. Reprint. 1887.

The Treatment of Neuralgia in General Practice. By Gustavus Elliot, A.M., M.D., New Haven, Ct. 1887.

Loisettian School of Physiological Memory, or the Loisettian Art of Never Forgetting, etc. By Prof. A. Loisette, 237 Fifth Avenue, New York.

The Rectum and Anus. Their Diseases and Treatment. By Charles B. Ball, M. Ch. Univ. Dub., F.R.C.S.I. With fifty-four illustrations and four colored plates. Philadelphia: Lea Brothers & Co.

The True Nature and Definition of Insanity. By C. H. Hughes, M.D., etc. Former surgeon United States Army, late superintendent and physician-in-chief Missouri State Lunatic Asylum, etc. (Reprint). 1887.

The Throat and its Diseases, Including Associated Affections of the Nose and Ear. With one hundred and twenty illustrations in color, and two hundred engravings. Designed and executed by the author, Lenox Browne, F.R.C.S.E., etc. Second edition, rewritten and enlarged. Philadelphia: Lea Brothers & Co. 1887.

Original Articles.

A COMPARISON OF GRADUAL DILATION, DIVULSION, INTERNAL AND EXTERNAL URETHROTOMY IN THE TREATMENT OF URETHRAL STRICTURE.[1]

BY F. S. WATSON, M.D.
Surgeon to Out-patients, Boston City Hospital, Surgeon to Genito-Urinary Department, Boston Dispensary.

[This paper is intended to be little more than a framework upon which to hang a discussion of the subject, and is limited to the operative measures in the title. Organic stricture only is considered.]

I shall assume that there are now comparatively few surgeons in this country who do not accept Dr. Otis's conclusions in regard to the calibre and varying sizes of urethræ, and the proportion between the circumference of the penis and the urethra it contains, that is, that people have different sized urethras just as they have different sized noses. The average urethra is 32 Fr.; that this sized urethra will be found in a penis which measures three and one-fourth inches in circumference; that for every increase of one-fourth inch in the circumference the urethra will be two millemetres larger. So that when we talk about restoring a strictured portion of the urethra to its normal calibre we have these figures in mind.

These statements are not accepted by many foreign surgeons. And the result of their operations are the less enduring by just so much as they are disregarded.

I also assume that strictures of the anterior urethra contract more readily after dilatation than those of the deep urethra, and that strictures of the meatus contract most readily of all.

Starting, then, on this basis, the operations may be considered in the order named, dwelling only on the two important factors affecting the decision of choice of method, namely, their relative dangers and the permanency of their results.

(1) Gradual dilation is generally agreed to be the safest method of restoring the calibre of the urethra. Its mortality does not rise above one per cent. The method cannot be advantageously applied to resilient strictures, to impermeable strictures, to such as are so dense that the force requisite to traverse them converts the operation into divulsion. And, last but not least, should not be continued where constitutional symptoms appear during its use. I have seen several times the advantage of the bolder course in these cases, the last being one upon whom I recently made three attempts to dilate a stricture at five and one-fourth inches. Each attempt was followed by chill, fever and retention. I divided the stricture, as well as some anterior ones, freely with internal urethrotomy. The patient has had not the slightest disturbance since. This experience, as well as others, reiterates the statement made by Sir Henry Thompson in relation to this point, who observes:

"In relation to those cases in which rigor almost always occur after passing a bougie, I know nothing so admirable as the results of internal urethrotomy... Even the operation will not be followed by any rigor, nor will the patient be likely to experience another throughout his subsequent treatment."

I do not know of any one who claims permanent cures of stricture by gradual dilatation, but by way of exception in newly-formed ones. The contrary opinion, is that generally and strongly expressed. Dr. Keyes, for instance, says: "Occasionally, I believe, cure results from dilatation of strictures of the deep urethera, but very rarely if the stricture has any pronounced fibrous character."

Dr. McBurney says: "I do not think that gradual dilatation ever cures an organic stricture of the anterior or posterior urethra."

Dr. S. W. Gross, in the discussion in New York in 1878, said "he considered dilatation utterly unavailing as a curative procedure."

Dr. Gouley, on this occasion, resorted to gradual dilatation first and tried to effect a cure by this means and had done so, having had some (how many not stated), cases under observation for ten years; where this did not succeed after a reasonable time he would do internal urethrotomy.

Mr. Berkeley Hill similarly says, unfortunately dilatation fails to obtain an expansion which does not shrink again, and with the exception of an early stricture is a most unsatisfactory process.

Dr. Weir thinks that dilatation is entirely ineffectual in the anterior urethra, but being safer in the deep than other operations uses it there when he can do so, but does not expect to cure by it. My own experience with dilatation is derived from the treatment of over a hundred cases, of which I have been able to keep some knowledge, and it accords with the opinions above in relation to permanent results. I have had six cases in which a cure seemed to result; all were of recent formation and wide calibre. In the rest I could never bring about a permanent result, often after trying months, in some cases years, and carrying the dilatation sometimes to overstretching. I have had one case of cystitis and pyelitis follow the use of sounds, and one of cystitis alone. The chief reason for using gradual dilatation is that it allows the patients to go about their business. In the deep urethra, except in those cases where rigors, etc., follow its use, it is safer than divulsion or internal uretrotomy. The method on the other hand is responsible for more bad urethras (false passages) than anything else. It happens to the most skilful occasionally to do damage to the urethra by the use of sounds, and just so much more often to those who have less skill and experience. The steel sound has a powerful leverage, and chronically inflammed mucous membrane is easily torn.

Divulsion is chiefly associated with the name of Perreve and Voillemier in France, and Holt in England. It mortality is from one per cent. to five per cent.

Total, 590 cases, with 23 deaths, + 3%

I know of no one who claims permanent cures by this method, but by way of exception. It is only fair to say, however, that but few operators carry the splitting or dilatation subsequent to it to sufficiently high numbers, an incompleteness which internal urethrotomy also labors under in Europe. Dr. Cabot tells me, that when this is done, he has seen enduring results. With this exception and the fact that early strictures in exceptional instances as by dilatation may be cured by this method, I have not found any

[1] Read before the Surgical Section of the Suffolk District Medical Society, Nov. 2, 1887.

claims to permanent cures. Personally, I have never seen one, but, on the contrary, have thought it the rule to find the relapses, which I have seen after the operation in the hands of those who practice it, associated with dense deposits of connective tissue, very difficult to dilate. In many of the cases recorded in the Massachusetts General Hospital and Boston City Hospital, of *relapsed* strictures, I have found, when admitted for tight, dense strictures, they had already had divulsion performed at varying dates previous.

The reason for this is to be found, I think, in the nature of the scar made by the operation of divulsion. The wounds inflicted are beyond guidance as to direction, extent and depth. There may be one clean longitudinal rent, or many, the direction is sometimes in the long axis of the canal, sometimes as a jagged tear obliquely across it. In these respects the operation not only lacks scientific accuracy, but what is more important, lays the foundation for denser and less tractable connective tissue than was originally there. *Outside* the urethra it will be conceded that a scar resulting from the rending or bruising of the tissues ends in greater impairment of function of the injured part, and larger deposit of connective tissue than a clean cut. Is there any reason to believe it will be otherwise *in* the urethra?

This theoretical reasoning and practical experience, so far as I have observed, support each other.

Like divulsion, internal urethrotomy had its origin in France, and has been extensively practised there ever since. The mortality is the same as that of divulsion, from one per cent. to five per cent.

Total, 2540 cases, with 82 deaths, + 2%.

My own experience is small, being limited to twenty-three cases, without a death or serious symptom.

Is there any difference between the two operations when applied to the deep urethra? The only one is the greater liability to hæmorrhage from deep cutting than from deep divulsion. I can find no greater mortality on the score of pyæmia, shock, infiltration, extension of inflammation, suppression, etc. It is, however, very rare to hear of a death from hæmorrhage due to deep cutting. But many of the most ardent advocates of the method do not cut beyond five inches, on account of this danger, or at any rate anxiety. But the great advantage claimed for internal urethrotomy is that it produces more cures and permanent results than any other operation. This advantage is claimed in varying degrees by different operators, as will be seen from the following quotations, in which I have included, also, the opinions of the relative merits of divulsion and internal urethrotomy as compared with each other.

Sir Henry Thompson, after giving it as his opinion that urethrotomy is the safest and best and most enduring in its results, does not claim much for it as a radical cure. "While I am free to confess that my experience does not warrant me in promising immunity from return, we may often regard the period of return as remote. Now and then I have met with a case in which the patient's troubles have not reappeared."

His opinion of divulsion is thus expressed: "Divulsion, at one time so much in vogue, now so completely and properly neglected."

Berkeley Hill, in *British Medical Journal*, 1879, in speaking of the two operations, says: "I have abandoned the use of divulsion for its unsatisfactory results. This is manifested, on the one hand, by the speedy shrinkage of the split tissue to its former narrowness, or beyond it, and on the greater difficulty which ensues on a second course of treatment, a new formation of fibrous tissue, the result of the operation occurs." Mentions two cases of divulsion which relapsed in eighteen and five months respectively, and were found much narrower and denser than at the first operation.

Internal urethrotomy is a safe proceedure, while it has this crowning advantage that it gives, in all cases, a period of relief from stricture always measured by years, and often by a long term of years.

Teevan, speaking of permanent results of the two operations in 1880 *Lancet*, October 2d, says: "I can state from personal examination of hospital and private patients years after they have been operated upon by different surgeons, that the tough non-dilatable cicatrices resulting from divulsion contrasted very unfavorably with the soft, supple, dilatable splices inserted by internal urethrotomy.

Coulson, 1884 *British Medical Journal*, Sept. 29th, considers that internal urethrotomy gives much the most enduring results. After divulsion the cicatrices often give rise to contractions as resistant as traumatic strictures.

A. Swinford Edwards thinks that relapsed strictures after divulsion are much more dense than the original disease was.

William Thornley Stoker, *Dublin Journal of Medical Science*, 1885, vol. 79, p. 410, says: "In the early years of my practice I performed divulsion frequently, and the best expression of my opinion in regard to it is that I have completely relinquished it for internal urethrotomy. The return of stricture after divulsion is as much the rule as it is the exception after urethrotomy."

In London, divulsion is practised now in only three out of fourteen hospitals. Internal urethrotomy is practised, as a rule, by Sir Henry Thompson, Messrs. Wood, Croft, Berkeley Hill, Annandale, Coulson, Jordan, Laud, Teevan, and many more of the best men in England. Are not these last two facts sufficiently suggestive? Especially are they so when we take into account that most of these men were brought up on divulsion, and all practised it.

In France we find varying opinions as to the relative advantages of the various operative procedures. These opinions were well mirrored in the discussion that took place last spring before the Societe de Chirurgie. Among the participants in the discussion were Le Fort, Tillaux, Trelat, Pollailon, Despres, Marc See, Horteloup, Le Dentu, Kirmisson, Terrier. The discussion followed a paper by Le Dentu, who compared twenty-four cases treated by divulsion with twenty-four by internal urethrotomy. Each set had two deaths. The society was about evenly

divided in its opinion as to choice between the two operations, but gave the preference to gradual dilatation, when it could be performed, to either. It is noticeable, however, that, as in England, but few radical cures are claimed. But in both countries *the old standard practically remains in regard to the extent to which the operation should be carried.* This, I think, is the reason why there is such a wide difference of opinion between American surgeons and those of other countries as to the permanency of the results. For here, the advocates of the operation claim *permanent cures of strictures anterior to five inches, as the rule;* by permanent cures, meaning a freedom from recontraction and the use of sounds for years, generally all their lives.

Dr. Otis, of New York, heads the list of those holding this belief, and asserts that if such strictures are thoroughly cut (according to the rules laid down in the beginning of this paper), and are kept open by the passage of sounds until healing is complete, they never return. From this, which is the extreme view of the situation, some of the differences may be seen by the following quotations:

Dr. Keyes says: "I always cut strictures of the pendulous urethra internally. This cures them radically, *as a rule.*"

Dr. McBurney writes: "I have a very poor opinion of divulsion for any stricture, and believe that it seldom cures. I do not think that gradual dilatation ever cures an organic stricture. Internal urethrotomy is my constant practice for all strictures anterior to five inches, and I expect a cure as a rule."

Dr. Bull practices internal urethrotomy and obtains frequent permanent results. Does not practice divulsion.

Dr. Weir practices internal urethrotomy as a rule. I do not know his opinion as to final results.

Dr. S. W. Gross, of Philadelphia, says: "All permeable strictures are best treated by internal incision, while for those situated within four and a half inches from the meatus it is the only method which holds out the slightest prospect of a radical cure. I have performed the operation too frequently not to be convinced of its superiority as to enduring results over all other methods."

My own experience is too small to contribute much to any decision, but I have been at some pains to follow the cases up, and as most of them have occurred in private practice, it has often been possible, as they are all directed to come twice annually for examination, and generally do so. The number is twenty-two. There have been no deaths, and no serious symptoms in any. No stricture has been cut that was deeper than five inches.

1.	6 years ago.	Internal urethrotomy. Uses no sounds. Has never recontracted since.	Has no symptoms.	
2.	5 years ago.	No sounds.	No recontraction.	No symptoms.

14 to 17 recent.
4 cases lost sight of.
22, Total.

Four were lost sight of after a few months. One of these, however, showed signs of recontraction before he went away, and it is interesting to note that in this case I did not divide the stricture thoroughly, having only a small Maissoneuve knife. One case has had, to my knowledge, to use sounds ever since.

With an occasional exception, then, in the cases I have been able to follow, the operation has given the patients entire immunity from periods varying from six years to one year. I cannot say that they may not contract again at some time in their lives until they and I have lived our lives, but they certainly show no disposition to do so. This, so far as it goes, forms a basis for a favorable opinion in regard to the operation. I cannot go so far as Dr. Otis in thinking that all cases properly cut are always cured, because I have seen strictures recontract after it has been done, and done well, too.

But what are we to do with deep strictures? It will be seen from the following that some surgeons hesitate to cut internally beyond five inches.

Dr. Keyes says he would never divulse or cut a stricture of the deep urethra. By preference he dilates such when possible. "In all cases of severe deep urethral stricture not suitable for dilatation I think best of external urethrotomy. I have tried all the operations a number of times, and can only give as the sum of my experience that final expression of opinion namely, the personal one. If I had a deep urethral stricture not suited to treatment by dilatation I would elect to be cut externally by a competent surgeon rather than run the risk of efficient divulsion or internal urethrotomy."

Dr. McBurney says: "In a tight undilatable stricture at five inches or beyond, I would always do an external urethrotomy. Nothing could persuade me to do a divulsion in such a case."

The opinions so decidedly expressed by two such good authorities are gaining ground in many quarters, and here it is that external urethrotomy puts in a claim as a competitor. Its mortality, based on a calculation of more than a thousand cases taken from Gregory's tables, Hourteloup, and other sources — since the days of antiseptics — is at the highest eight per cent.: if the figures are sifted it becomes three per cent., but let the figures stand, as in the other calculations, at their face value. In the earlier days the mortality was much higher, due to to the fact that dirt reigned supreme, as is shown by the large number of deaths due to pyæmia and septic processes; and, also, because the operation was rarely employed except as an emergency operation. I have only done the operation eight times without mishap.

I would call attention to the fact that when perineal section is performed for purposes of exploration of the bladder, no stricture being present, there has been practically no mortality. This gives a good idea of the danger of the operation *per se.* Its danger where long-standing deep-seated stricture is present, is at its height. Here it isn't the operation that kills, but because we are obliged to operate when the patient is prepared for death by renal complications and a broken constitution. The less serious the stricture the less risk in the operation. And, although I cannot furnish figures to support this view, I feel safe in saying that if the operation were performed earlier the mortality would compare favorably with that of divulsion or internal urethrotomy. Once a deep stricture is beyond the control of dilatation it seems to me best treated by external urethrotomy. And I would suggest that the

operation be not reserved until retention and extravasation are actual present dangers, but do it while the urethra is still permeable for a guide. The permanency of results are not so good as those of internal urethrotomy, so far as I can learn, though they are sometimes enduring, as in a case which I recently saw, in which Dr. Cheever performed the operation seventeen years ago, and the patient has only recontracted to a small size recently, and has entirely neglected his urethra in the interval. Dr. Keyes tells me, also, that he has radically cured a severe traumatic stricture by this operation. A reason why, as a rule, the results are not so permanent may, perhaps, again be found in the same reason that affects the mortality, namely, that the cases so dealt with are only the severest forms, and consequently even with a guide we can seldom divide the strictured portion with one clean cut. The cut must often be extensive, and long in healing, exposed to the air, the contact of dressings, etc.

One of the objections always urged against external urethrotomy is that it is liable to leave a urinary fistula afterward. I do not know the exact proportion of cases in which this is the case. Again, it is probable that if the operation were done earlier the healing would be more complete, and fewer fistulæ would result. It is by no means a great misfortune to have a fistula, and it may be a safety-valve. A great deal of discomfort may be avoided by using a catheter. In the first case I did the patient has today a fistula. He can urinate by the natural channel without a drop coming by the fistula by standing with his legs slightly crossed. Moreover, such urinary fistulæ can often be closed by plastic operations, so that their number may be reduced. The immediate union of the wound by suture also aids in securing this end.

(1) *Conclusions.* All strictures anterior to five inches are best treated by internal urethrotomy. Dr. Otis's operation yields the most enduring results.

(2) Divulsion should be rejected as an operation for stricture, unless it can be shown satisfactorily that where carried sufficiently far it yields as permanent results in as many cases as internal urethrotomy.

(3) Dilatation where practicable should be employed in strictures deeper than five inches.

(4) For strictures deeper than five inches not suitable for dilatation external urethrotomy should be selected, and not reserved for an emergency operation only.

A CASE FOR THE MEDICAL EXAMINER.

BY S. D. PRESBREY, M.D.

ON Saturday, June 11, 1887, I was visited by a young man, who resides in a farming-district about ten miles from Taunton. He wished to notify me of a sudden death and to ask for investigation, since he had been informed by the physician who had been called, that such was the proper course. From my visitor I learned in substance the following facts. The dead body was that of a young woman twenty-one years of age, who had been living as a domestic in his father's family. The family consisted of his father, an elderly man, whose wife had been dead two years, and his brother, unmarried, about twenty-five years of age. He himself, and his two sisters, all married, lived in the vicinity. This domestic came into the family seven years ago, and at first acted as assistant, but at the death of his mother became the housekeeper. She had relatives in Ireland, and one sister, who was then on her way to this country, was daily expected. She had no relatives in this country except an aunt, with whom she was said not to have been on good terms. My informant and all the members of the family with whom I afterward conferred, spoke in the kindest terms of the young woman, and from no one of them could I learn anything unfavorable, either as to her character or her ability.

On this Saturday forenoon my informant was at work with his younger brother, the one mentioned above, planting upon their father's farm. His father was not at home, having gone out of town on business. The young woman had attended to her household duties as usual, and was supposed to be preparing to go with his sister to a neighboring city to do some shopping. At 11.30 the young man went to the house to get seed for planting, and on entering the house he heard groans, which appeared to come from a room in the second story. He went up-stairs, as he says, and found the door of the girl's room locked. The groans continued and he got no answer to his repeated calls. Failing to fit the lock with any keys which he had with him, he forced the door open and found the young woman quite naked, sitting in a wash-tub partly full of water, leaning back and unconscious. He placed her upon her bed, covered her with blankets and at once notified his brother, his sister-in law and his sisters, who all live not far from his house. A physician was summoned, but before he arrived, and within a few minutes after having been placed upon the bed, she ceased to breathe.

This history was given by the young man and was evideutly accepted by all members of the family as correct, nor has any doubt been thrown upon it by any thing that has been since learned.

The room and its contents had been left for my inspection, exactly as found. The young woman's clothes were lying upon a chair, there was soiled water in a wash-tub, soap-dish with soap stood near, towel was handy, and in short the room justified the opinion that she was in the act of taking a bath.

The body showed no marks of violence, and from the view and inspection no satisfactory theory of the cause of her death could be formed. A conference with the selectmen of the town, to whom the above report was made, resulted in a request that an autopsy be made, and if necessary a chemical analysis of organs. After the necessary preliminaries, on Sunday morning the autopsy was made, of which the following is the report. Twenty hours after death, rigor slightly marked; body, full and round; pupils, evenly but not widely dilated; slight "black-and-blue spot" upon the middle of the left clavicle; front of body pale, back, purplish red; no froth or bloody matter about mouth or nostrils; external orifice of vagina patulous, easily admitting two fingers; hymen not seen; rugæ of vagina, coarse and hard; nothing more learned by inspection.

Internal examination. Cut surface of scalp bloody, and an excess of fluid blood found in veins and sinuses, especially in dependent portions; nothing abnormal in the brain; incisions show no traces of air in the circulation; trachea lined with a delicate coat of bub-

[1] Read before the Massachusetts Medico-Legal Society, October 5, 1887.

bling mucus, not bloody; lungs, spleen, liver and kidneys engorged and of dark color, more especially in dependent portions; large veins filled with dark liquid blood, no clots found. The large vessels about the heart were carefully tied. The heart was small and soft, but otherwise apparently normal, and quite empty. The uterus was removed with its appendages and the upper part of vagina; the os uteri was entirely plugged with mucus, not bloody, and never having been disturbed; uterus about four and a half inches long and three inches wide at the fundus; the membranes were unruptured, and containing liquor amnii and a fœtus measuring from head to caudal curve one and three-quarters inches; the umbilical cord was not spiral; the interior of the uterus showed no marks of violence; the right ovary contained a distinctly marked corpus luteum; other organs normal in appearance.

Portions of the brain, liver, kidney and the stomach complete were sent to Dr. William B. Hills of the Harvard Medical School for examination. The following is his report:

"I have completed the analysis of the organs of —— ——and do not find anything to account for death. The stomach contained one-half ounce of semi-fluid brownish contents which from microscopic examination were found to be composed in great part of remnants of food, namely, fat, starch, partly digested muscular fibre and more or less vegetable tissue the exact nature of which could not be determined. The contents of the stomach contained also a small amount of sulphate of iron. The presumption is, I think, that this was taken in the form of a pill, with perhaps aloes or something similar. I think I am right in believing that such pills are sometimes taken under the impression that they will cause abortion. At any rate I have met with two cases in which such pills (containing sulphate of iron) have been administered by abortionists for this purpose. I do not think, however, that there is the slightest reason for supposing that the sulphate of iron was the cause of death. The amount present was small, and there was no evidence of any inflammation of the mucous membrane of the stomach.

"Chemical analysis of the stomach and contents showed the absence of all the *ordinary* poisons. The tests for most of the substances employed as abortifacients are not so well-defined as those for the ordinary poisons, and for detecting them we have to rely to a considerable extent on the microscopical examination, being aided at times by the odor. I did not, however, discover anything on microscopical examination which suggested the use of any abortifacient which may be detected in this way, and there was no indication to the sense of smell of any of the essential oils, neither could any essential oil be detected by chemical analysis.

"I think I should add, in order to make the report as complete as possible, that at one point on the mucous membrane of the stomach, was a slight brown deposit, and a portion of the deposit was sulphate of iron; I could not determine the nature of the remainder. There was nothing characteristic about it when examined beneath the microscope, and analysis threw no light on its nature. I think it was some vegetable substance; and there is a large number of these for which there are no known tests. It was the occurrence of this deposit, which led me to think that the sulphate of iron was administered in pill with some organic substance."

"(Signed) William B. Hills."

After careful deliberation upon the facts of this case, it was thought best to submit the following return, "that —— —— came to her death by natural causes, the exact nature of which was not disclosed, autopsy and chemical and microscopical analysis giving only negative results."

Though we were unable to arrive at an exact diagnosis in this case which we could record with a conviction of its absolute accuracy, several theories of the cause of death came up for consideration.

First, the theory of poisoning, whether accidental or intentional, would seem to have been set aside by the examination of Dr. Hills, and his report lends weight to the idea that she was only using ordinary and simple means to induce the appearance of her menses, such as the aloes and iron and the warm water sitting-bath.

Again, our history of her position and condition when found, rests entirely upon the evidence of one person, who might possibly be an interested party. The circumstances, however, seem to corroborate his statements. Yet, if in the face of his statements and of the circumstances, we were to consider the possibility of death by smothering and arrange the evidence in order, we should find fluid blood in the larger veins and sinuses; lungs, spleen, liver and kidneys engorged; no clots; bubbling mucus, not blood-stained, in the trachea; no blood about the mouth and nostrils; heart quite empty (even the right heart); and no appearance of subpleural ecchymoses — a condition that would hardly warrant the diagnosis of death by smothering.

Taylor describes a mode of death which he calls syncopal-asphyxia, in which the symptoms substantially as above mentioned may be expected, and it seems worthy of consideration whether a pregnant woman, anxious as to her condition, hurrying through her work (to be in readiness to go out with a friend), and immediately sitting in a tub of warm water, may not become faint, and leaning helplessly backwards over the edge of the tub, may she not become so exhausted that nature may fail to rally, even if the body has been placed in a horizontal position before respiration has ceased? I am not prepared to say that this theory of the cause of death is quite satisfactory, yet I have been unable to suggest a theory that meets the circumstances of the case any more fully.

CASES OF URETHRAL STRICTURE, TREATED BY ELECTROLYSIS.[1]

BY G. W. ALLEN, M.D.,
Surgeon in the Genito-Urinary Department, Boston Dispensary.

The following cases of stricture were treated by electrolysis, the method employed being essentially that advised by Dr. Newman, of New York, and Mr. Clark, of St. Bartholomew's Hospital, London. The calibre of the stricture having been measured, a bulb-electrode one or two sizes larger is passed down to it and connected with the negative pole of a galvanic battery. The positive pole is attached to a broad

[1] Read before the Surgical Section of the Suffolk District Medical Society, Nov. 2, 1887.

metallic electrode, covered with wet absorbent cotton (or a sponge electrode), which is held against the abdomen or elsewhere. The strength of the current used should be from three to five milliampères. In the cases reported it was four milliampères; a little less in the last case. The electrode will generally pass through the stricture within half-an-hour, only the gentlest pressure, if any, being exerted. The operation is painless. Very little after-treatment is indicated. In these cases ten grains of quinine were given after each operation, and the patients were advised to keep quiet for a day or two. After an interval of a week or more, not less, the urethra is examined to ascertain the result of the operation.

CASE I. G. T., twenty-eight years old, was first treated for stricture two years ago. His urethra is very sensitive and he has several times had chills after the passage of sounds.

Strictures of a calibre of 19 (French scale) were found at $\frac{1}{2}$ inch and at 2 inches from the meatus, and one of 16 at $3\frac{1}{2}$ inches. The first stricture was treated by electrolysis May 7th. Electrode No. 20 was placed against the stricture and with a current of 4 milliampères it passed through in 20 minutes. Within 12 hours the patient had a severe chill, with fever and vomiting, and was quite ill for several days. He returned to the Dispensary in about a month, but the result of the operation could not be accurately ascertained, as he had meanwhile been treated by gradual dilatation at the City Hospital. This latter treatment was continued.

CASE II. J. H., fifty-three years old, had strictures admitting 17 at $1\frac{1}{2}$ and $1\frac{3}{4}$ inches. May 24th, electrode 18 passed both strictures in 10 minutes. Although there was no chill, the operation was followed by malaise lasting a week, with considerable local irritation and a copious discharge. The strictures were found to have contracted to 14 and the treatment was abandoned.

CASE III. E. J., thirty-nine years old, had his first gonorrhœa eighteen years ago and symptoms of stricture fifteen years ago. He came to the Dispensary with a chronic discharge and, when examined, was found to have strictures as follows: at $\frac{3}{4}$ inch 22, at $1\frac{1}{2}$ inches 18, at $2\frac{1}{4}$ inches 14. July 28th the middle stricture (18) was electrolyzed and electrode No. 20 passed through in 15 minutes. The operation caused no constitutional symptoms whatever, but some local irritation with increased discharge and painful micturition, on account of which, examination was delayed, and the patient was lost sight of until September 22d, when the stricture operated upon and the one posterior to it were found to be the same size as before, while the anterior stricture had contracted. He had had no treatment meanwhile. Two days later electrode 17 was passed through the narrowest stricture (14) in 20 minutes. This was followed by no constitutional symptoms and by less local disturbance than before. One week later (October 1st), bougie à boule 18 was passed easily through all the strictures. The urethra was very sensitive. October 8th, a bulbous bougie No. 19 was passed, meeting with some resistance at each stricture. Electrode No. 20 passed all three strictures in half-an-hour. October 20th, the strictures were defined by bougie à boule 21, 22 passing with slight difficulty. Another operation was begun, but when, in about 15 minutes, electrode No. 25 had become engaged in the first stricture, the patient suddenly became faint, and nothing further was attempted. He has not since been seen.

CASE IV. J. C., twenty-eight years old, began to have symptoms of stricture four years ago, and complete retention two years ago. On examination, he was found to have a series of strictures, gradually diminishing in size from 25 at $1\frac{1}{4}$ inches to 11 at $3\frac{1}{4}$ inches and at 5 inches. August 23d, electrode No. 15 was passed to the first of the two narrowest strictures (11) but failed to pass in 20 minutes. This operation was followed by no constitutional symptoms, but by increased discharge, difficult and painful micturition, and a great deal of swelling and induration about the seat of the stricture. The size of the stricture was apparently unchanged. It was deemed advisable to discontinue this treatment and gradual dilatation was substituted. A smaller electrode would probably have been better in this case, but was not at hand.

REPORT ON FOODS, DRUGS, AND THEIR ADULTERATIONS.

BY BENNETT F. DAVENPORT, M.D.

EXAMINATION OF PEPTONE PREPARATIONS.

THE variable composition of the so-called peptone preparations of the market led August Hirschler [1] to make quantitative estimations of them for both the true nutritive peptones or allied bodies, and the less nutritous ones. He precipitated the nutritive peptones by means of phosphotungstic acid and estimated the amount of nitrogen they contained, and he also estimated the total amount of nitrogen in the preparation, and, subtracting one from the other, obtained the amount of nitrogen equivalent to the non-nutritious nitrogenous material present. The following table shows his results:

	Koch's	Kemm'rich	Witte	Weyl	Simon
Total percentage of Nitrogen	8.08	10.04	13.3	12.68	10.15
Percentage of nitrogen from non-nutritious nitrog. Substances	10.7	9.72	9.21	13.9	9.86

According to the investigations of Kühne and Chittenden,[2] albuminoids digested by means of the pepsin ferment do not form true peptones, but do form hemi-albuminose which is identical with the propeptone of Schmidt Mülheim, and which must be considered as an intermediate product between albuminoid material and peptone. Kühne and Chittenden found in the resulting products from the digestion of albumen with pepsin, four different kinds of albuminoids, but in the peptone preparations of the market said to be made in this manner, no peptone at all, or only mere traces were detected.

The hemi-albuminoids differ from albumen in their solubility in hot water in dilute-salt solutions, and in their behavior toward weak acid solutions, and property of separating in the cold. They also differ from true peptones by dialysing slowly, and by being precipitated by common table salt, by this and acetic acid, and by acid or alkaline solutions of ammonium sulphate.

[1] Zeit. chem. Ind., 1887. Heft. 2, 62.
[2] Zeit f. Biologie, 1883. Bd. 19, 159, and 1884, Bd. 20, 1.

Koenig [3] says that commercial so-called peptone preparations should more correctly be called meat albuminoids (fleisch albuminosen), while the term meat peptones should be bestowed only on those preparations which are the result of pancreatic digestion.

MEAT EXTRACTS AND BOUILLON EXTRACTS.

In the table given below will be found the analysis made by Rudolph Sendtner[4] of the meat and bouillon extracts of the market, the method used being the one published in volume one of the *Archives für Hygiene.*

	Water.	Ash.	Organic Substances.	Nitrogen.	Soluble in 80 per cent. alcohol.	Chlorine Present in the ash
	%	%	%	%	%	%
1. Pastoril Meat Ext.	15.50	26.23	58.27	—	61.74	—
2. Pisoni's Ext. of Meat	17.73	19.68	62.58	—	64.68	—
3. Kemmerich's argent. Fleish Ext.	18.88	19.46	61.66	—	59.06	—
4. Cibils' Ext. Carnis	19.41	26.43	54.15	—	62.86	21.32
5. Liebig Ext. av. of 170 analyses	18.79	23.02	58.19	8.00	61.85	10.00
6. Saladero Concordia	21.88	15.85	62.27	9.64	58.29	—
7. Peptone de viande, Kemmerich	34.27	7.70	58.02	9.36	28.40	—
8. Cibils' Hermanos (fluid)	64.12	18.29	17.58	2.10	34.28	44.45
9. Koch's Peptone Bouillon	59.58	15.88	24.54	3.65	32.78	43.19
10. Kemmerich's Cond. Fleisch Bouillon	62.59	17.06	20.35	3.13	29.32	41.97
11. Maggi's Bouillon Ext.	68.64	23.80	7.56	1.29	25.79	57.23
12. Bouillon Conc. Morris Canning & Co.	64.24	13.40	22.35	—	29.87	—

The first four preparations have a composition similar to that of Liebig's extract. Cibils' extractum carnis and Pastoril's fleish extract have probably had salt added to them. Numbers eight to twelve are fluid extracts, or bouillon extracts, and according to the amount of nitrogenous material present in them, stand in the following relation: Maggi, 1; Cibils, 1.62; Kemmerich, 2.43; Koch's, 2.84; Liebig's, 6.10. The amount of chlorine found in the ash is the guide to the amount of salt added to these preparations. If we subtract the normal amount (ten per cent.) of chlorine which is found in the ash of a true meat extract from that found in the ash of these preparations, we find that Cibils has had 56.7, Koch's 54.69, Kemmerich's 52.68, and Maggi 77.83 per cent. of the salt which they contain added to them. As regards flavor the author considered that Cibils ranked first in tasting more like beef soup. This is not true of the other preparations. If a little salt, and perhaps some water, be added to the well-known Liebig's extract a bouillon can be prepared, at a considerable saving of expense, which will compare very well with the bouillon preparations of the market that are now so highly praised.

THE NATURE OF PEPSIN.

Carl Sundburg [5] has undertaken to show that the ferment pepsin is not an albuminoid body, and that albuminoid reactions that are obtained from the so-called pepsins are due to foreign materials contained in them. He claims that by subjecting the pepsin to successive dialysations a solution is obtained which has powerful digestive properties, and which responds to no tests for albuminoids.

SACCHARIN.

According to Maumené,[6] Fahlberg's saccharin is allied to taurin. He claims it consists of two substances which differ in their solubility in water and alcohol. These substances can be separated by forming double salts with sodium chloride. One of the substances contains 12.98 per cent. of sulphur, the other 15.6 per cent, the latter alone containing the powerful sweetening principle. Saccharin is said to be prepared from toluol. It is a white powder, acid in reaction, slightly soluble in water. If the acidity be neutralized with potassium carbonate or hydrate, its solubility in water is increased. It has an odor not unlike bitter almonds, and is 280 times sweeter than cane sugar.

Saccharin is now principally used to sweeten the food of diabetic patients.[7] It has no nutritive value.

Aducco and H. Mosso have found that urines which contain it resist fermentation for a long time. Pollatchek [8] has used it to disguise the taste of drugs, and since its solubility is increased by alkalies he combines it with sodium carbonate, as in administering quinine.

EUCALYPTUS HONEY.

Guillmette [9] obtained in Tasmania specimens of honey which were deposited on eucalyptus trees by a specimen of black bee. The honey had a strong odor of eucalyptus, and when taken internally is said to diminish the frequency of the heart's action. When mixed with milk or water it makes a very pleasant drink. It is highly praised in diseases of the throat and lungs by some.

ARTIFICIAL BUTTER.[10]

As an extra precaution in the sale of the above product it is recommended by a food journal in Germany that the government require manufacturers to comply with the three following conditions: (1) Every artificial butter manufactory must be under the surveillance of German officials; (2) every 100 kilos of artificial butter must have one gram of phenol-phtalein added to it; (3) Failure to comply with the second condition is punishable by a fine of five hundred marks for a first offence. For a second offence a fine of one thousand marks to be imposed, and the right to carry on its manufacture to be revoked.

The presence of phenol-phtalein in artificial butter allows the latter to be easily detected should natural butter be adulterated with ten per cent. of it. All that is necessary to detect it is to add an alkali as potassium hydrate, or even cigar ashes, to the sample, and an intensely red color is obtained.

Penol-phtalein is non-poisonous, has no physiological action, and hence does no harm when added to the butter.

NEW ARTIFICIAL BUTTER LAW.[11]

At a meeting of the German artificial butter manufacturers held in Frankfort on August 13th and 14th, attention was called to the new artificial butter law of the Canton St. Gallere, where the government requires that all artificial butter should contain at least twenty-five per cent. of natural butter. The German manufacturers considered that they were submitted to hardship in not being allowed to improve their products in the same manner, as their law forbids any admixture.

NEW METHOD OF PRESERVING BUTTER.[12]

M. Pierre Grosfels, of Vervier, has communicated to the "Société d'encouragement de Vervier," a process for preserving butter for a long period, so that it may be imported into countries the climate of which does not permit it being made there, on account of the very high temperature. It consists of working the butter in water containing two per cent. of lactic acid, and two per cent. of one per cent. of salicylic acid. The process is stated to be very economical, as the antiseptic liquid will serve indefinitely being unalterable, and its cost is but slight.

"NORMAL" PAPER.[13]

Those who have recently visited Germany could not have failed to notice the extensive sale Prof. Gustav Jaeger's "normal" underwear was having, and may be interested to know that he has suggested a method for the manufacture of "normal" paper. He calls attention to the unhealthy property ordinary paper has of absorbing disagreeable odors or vapors, and again giving them off in moist atmospheres. This he best illustrates by the odors noticeable in large libraries and document rooms, on a wet day. He suggested that a paper be manufactured from vegetable fibre, not unlike parchment, which has not the above disagreeable property, and he now has manufactured under his supervision at the Balsthal Solothurn paper manufactory, the following varieties:

(1) Packing paper, free from coloring matter and bleaching materials, to be used for food products.

(2) Writing paper, and paper for printing purposes, which contains a slight amount of clay, but which is also free from coloring matter and bleaching materials.

(3) Writing paper free from clay and other matters. This is thin and transparent and allows writing only on one side.

A NEW SUBSTITUTE FOR THE POTATO.[14]

At a recent meeting of the "Société Nationales d'Agriculture" in Paris, Mr. Triana, of Columbia, South America, showed two varieties of the Arrachacha esculenta. These plants, he said, belong to the family of umbelliferæ and the tubers are not unlike medium-sized turnips in shape. It is sweet and mealy, and during the recent potato disease in Columbia, they were found to be fitting substitutes for the potato. Attempts have been made to cultivate them in France, but thus far with poor results. Experiments are now being carried out by the Agricultural Society of Paris, and it remains to be seen whether it can be cultivated sufficiently to be of commercial value as an article of diet.

TERPIN HYDRATE AND TERPIN OIL.[15]

These are among the latest of the terpenes and camphors introduced into medicine. Terpin hydrate is formed by mixing oil of turpentine, alcohol and nitric acid in the cold, where it separates as large rhombic crystals, easily soluble in water, alcohol or ether. Terpin oil is formed by the action of dilute sulphuric acid on terpin hydrate. Terpin hydrate is only superior to oil of terpentine in being less aromatic.

EXTRACT FILICIS MAS.[16]

This extract is usually required to be of a deep green color, such being preferred to the brownish green. Weppen and Ledders report in the *Berlin Ph. Ztg.*, that it is impossible to obtain a green extract with the exclusion of metallic copper vessels in its preparation. It owes its green color, when present, to copper, or to added chlorophyl.

PHENYL COCAINE.[17]

A preparation of this name is said to be an effective local anæsthetic in dentistry. It is prepared according to G. Viau[18] by heating one part phenol with two parts cocaine. It is not as yet known whether an actual chemical combination takes place or not.

SALICYLATE OF SODIUM.[19]

It is asserted that considerable quantities of this salt are now offered which contain much more sodium than is necessary to make the salt, in other words, a large amount of uncombined carbonate or bicarbonate is present as an adulterant.

ADULTERATION OF COFFEE.[20]

L. Padé, chemist in Paris, calls attention to two new methods of adulterating coffee. (1) Coffee that has been damaged at sea is freed from the sea salt by washing, and is then bleached with lime, again washed, and then either partially roasted or colored with an azo color. (2) This second method is used in roasted coffee, the intention being to increase its weight as high as twenty per cent., by either moistening it with water or impregnating it with superheated steam. Coffee treated in this manner can best be detected by taking the specific gravity, or by estimating the loss of weight, caused by exposing it in a drying oven to the temperature of 110° C. for six hours. Good roasted coffee never losing more than one or two per cent.

If the specific gravity is below 1,000, look out for damaged coffee which has been partially roasted. Dye stuffs can be detected by placing the coffee in alcohol, when, if they are present, the color will appear in the alcohol.

A NEW TEA.[21]

Attention is being called to a new kind of tea, the so-called coffee-tea, which is made from the roasted leaves of the coffee-tree. It is said that when the leaves are thoroughly roasted, and an infusion is made, a dark brown liquid is obtained. This looks not unlike coffee prepared from the beans. It smells like green tea and tastes like a mixture of tea and

[21] Handels-Bericht Gehe & Co. April, 1887.

coffee. The coffee leaf contains about one-half as much of caffeine as the beans.

MATTA.

This substance, which is used largely as an adulterant in spices, varies greatly in its composition according to the spice it is intended for. Hanausek[22] found its chief constituent to be millet bran. Nevinny[23] finds the so-called pimento-matta to consist of powdered dried pears.

GALAZIMA.[24]

This is said to be a milk preparation not unlike koumis and kephir, and is prepared as follows: four parts of yeast are dissolved in water with ten parts of sugar, and added to 1,000 parts of milk, the whole being thoroughly shaken. After standing twenty-four hours, the preparation is ready for use. It should contain about one per cent. of alcohol, and be saturated with carbonic acid gas.

COLORLESS HYDRASTIS.

Examination of commercial samples of the above preparation, by G. Steinmann,[25] shows it to be nothing but a solution of hydrastin in dilute sulphuric or hydrochloric acids. Boracic acid was also found in some samples.

CONDURANGO WINE.

Condurango bark, which fifteen years ago was highly recommended as a cancer remedy has now fallen into line again. This time as a stomachic, in the form of a wine. The best preparation is made according to G. Vulpius,[26] by macerating one part coarsely-ground condurango bark in ten parts of sherry wine for eight days.

Clinical Memorandum.

A CASE OF BACKWARD DISLOCATION OF THE THUMB UPON THE METACARPAL BONE, IRREDUCIBLE BY MANIPULATION: REDUCED BY CUTTING DOWN ON THE JOINT.[1]

BY J. W. ELLIOT, M.D.

THE patient was a waiter, thirty-four years old. On April 29th, while engaged in packing a trunk, he fell backwards and doubled his right thumb back on his hand. His doctor tried in vain to reduce it, using much force in pulling. He came almost immediately to the Massachusetts General Hospital, where he was seen by Dr. Elliot. The right thumb was dislocated backwards upon the metacarpal bone. Two facts were noted as peculiar; first, *head of the metacarpal pointed almost straight out towards the palm of the hand;* second, a very rigid muscle could be seen and felt running across the metacarpal bone to the first phalanx.

After one or two ineffectual attempts to reduce the deformity, ether was given. Even under ether, both Dr. Harrington and Dr. Elliot found reduction impossible. All the known procedures were tried in vain. On cutting through the skin and fat, the glistening head of the metacarpal bone appeared completely stripped of all its ligaments. It had pushed through between the heads of the flexor brevis pollicis muscle. In this position it was firmly held by tense muscular bands on both sides of the neck of the bone. The tendon of the flexor longus pollicis was round under the head of the bone in such a manner as to reinforce the posterior and deeper part of the flexor brevis. In this position every attempt at reduction, only locked it tighter.

The tendon of the flexor longus pollicis was first hooked up over the head of the metacarpal bone and even then it could not be reduced; but when the anterior head of the flexor brevis pollicis was pulled forward, the bones easily slipped into place.

The wound was closed with one cat-gut suture and a dry gauze dressing applied. The patient was treated as an out-patient. There was no pain and no swelling. The wound was first looked at at the end of ten days when it was found healed by first intention. The patient has now a perfectly useful thumb. The result is surprising when we remember that the joint was torn completely apart and that the tendon of the long flexor was pulled out of its sheath for at least an inch.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

G. H. MONKS, M. D., SECRETARY.

REGULAR meeting at 19 Boylston Place, Wednesday, November 2, 1887, DR. J. COLLINS WARREN in the chair. In the absence of the Secretary, DR. H. W. CUSHING acted in that capacity. On motion of DR. BRADFORD, DR. WARREN was elected Chairman for the coming year.

After thanking the members for their kindness in re-electing him, DR. WARREN called for the first paper, which was

A CASE OF DISLOCATION OF THE THUMB REDUCED AFTER CUTTING DOWN UPON THE JOINT.[1]

by DR. J. W. ELLIOT. After reading his paper, Dr. Elliot said: When I did the operation I found the tendon of the long flexon wound about the head of the bone in such a way as to give the impression that this tendon was the principal obstacle to reduction. In point of fact, however, after I had slipped the tendon over the head of the bone, I could not reduce the dislocation, and I therefore concluded that the position of the long flexor tendon had little or nothing to do with the irreducibility, a fact which I verified by experimenting on the cadaver.

Dr. Elliot then presented the man on whom the operation had been done, and remarked that the use of strict antiseptics now enable the surgeon to explore at will and to open the joint if necessary; at all events to thoroughly see the condition of things before attempting to remedy it by some of the expedients recommended in the text-books, such as tenotomy or resection of the head of the bone.

DR. F. B. HARRINGTON then presented a boy who had suffered a similar dislocation of the thumb, and

[1] See page 625 of the Journal.

said: This case as often happens, presented itself about two weeks after Dr. Elliot's case. It differed from the latter only in the position of the tendon of the long flexor which lay to the radial side of the head of the metacarpal bone. This position of the tendon is very unusual, but it is possible on the cadaver to dislocate it to that side. The dislocation had occurred on the previous day and its reduction had been attempted outside the hospital. The phalanx rested upon the dorsum of the metacarpal bone and was parallel to it. All efforts, with and without ether, failed to reduce the dislocation. An incision was made over the head of the metacarpal bone which projected toward the palm and which seemed subcutaneous. After cutting down where you could see the joint it was still impossible to reduce. Finally, by passing a director under the external head of flexor brevis, and dragging this head over the head of the metacarpal bone, the bones slipped into position. Nothing but the skin and subcutaneous tissues had been cut by the operation. The wound healed by first intention. Within three weeks the boy was using the thumb and it has given him no trouble since. The motion is good, nearly perfect it might be said. There is still a little thickening in the region of the incision.

I would like to say a word or two about the anatomy of the metacarpo-phalangeal joint of the thumb. Dr. E. O. Otis[2] has recently written an interesting paper on the same dislocation in the fingers.

The ligaments of this joint of the thumb are the anterior, the two lateral and the posterior. The anterior or "glenoid" ligament resembles that of the fingers. It ruptures at the metacarpal attachment almost without exception. This makes a long flap which may get between the ends of the bones and prevent reduction as in the fingers. In this anterior ligament are the two sesamoid bones which are also connected with the two heads of insertion of the flexor brevis muscle. These two muscular heads are joined one by the abductor pollicis on one side, the other by the adductor pollicis on the other side. The phalangeal portion of the anterior ligament is made up of tough, almost cartilaginous tissue which is quite thick and strong. The lateral ligaments are also stout bands which are connected with the sesamoid bones and the anterior ligament. By means of these muscles and the lateral ligaments, which do not usually rupture, the flap of the anterior ligament is dragged and held down behind the head of the metacarpal bone.

It is frequently possible to reduce this dislocation by proper manipulation, occasionally, however, the most experienced fail. An operation is then necessary. Resection is a severe operation which leaves at best, an imperfect finger. The subcutaneous operation is blind, unsatisfactory and sometimes unsuccessful. Important tissues may be injured and permanent disability result. The following are directions given by Dr. J. E. Kelly,[3] for the use of the tenotomy knife in case of irreducible dislocation of the thumb. "If an intelligent trial of reduction by manipulation should fail, a subcutaneous operation upon the posterior surface might be adopted, which is rational, easy, and safe, and which should not be such a source of persistent weakness. To the outer side, of, or between the extensor tendons, a tenotome might be passed through the skin down to the anterior margin of the base of the phalanx and through the intersesamoid space, until it would reach the back of the metacarpal bone, upon which might be divided all the structures forming the anterior wall of the articula fossa. Thus the 'button-hole' slit would be extended at least by half-an-inch in the most advantageous direction, and should reduction be still impossible, the structures lying to the outer side of the head of bone might be divided, and, if still more freedom be desired, the subcutaneous incision could be converted into an open wound, when the internal boundary of the 'button-hole' could be reached from the most advantageous aspect. A hook or lever might be applied to the metacarpal head and retractors also would aid the readjustment, a loop of wire passed through the 'button-hole' should make direct traction backwards on the metacarpal head, while separating the lateral margins of the aperture."

This certainly does not suggest a perfectly simple operation. The point which I wish to make is, that with an irreducible dislocation of the thumb, the best procedure is to carefully dissect down to the dislocation on the palmar side, and to reduce without farther injury to the important structures of the joint. That this can be safely and successfully done, is shown by the cases presented to-night.

DR. OTIS said: I have been exceedingly interested in the report of these two cases, and the exhibition of the patients showing such perfect results. The reduction of a dislocation of the thumb or fingers — a dislocation upon the metacarpus — is not always the simple and easy thing which many authors make out, and to go through life with an irreducible dislocation of this joint is a grave misfortune.

These two cases illustrate one of the three causes generally given by authors which prevent the reduction of the dislocation of the thumb by manipulation, namely, the catching of the head of the metacarpal bone between the two heads of the short flexor. The other two causes are the interposition of the glenoid ligament, and the locking of the head of the metacarpal bone between the two lateral ligaments. I know of but one other reported case, that of Ranke's,[4] where a dissection was made on the palmar surface, as in these cases, for an irreducible dislocation of the thumb, and in this case the cause of the irreducibility was found to be the interposition of the glenoid ligament, which, as I have elsewhere shown, I believe to be generally if not always the cause of an irreducible dislocation of the fingers. In the case of the thumb, however, a new element comes in to prevent the reduction, namely, the two heads of the flexor brevis muscle. Previously, in irreducible dislocations either in the thumb or fingers, if operative interference has been attempted, it has been either a resection, or a groping about in the dark with a tenotome with no definite idea of what needed to be cut; not a clean dissection to discover the cause of the irreducibility, as in these cases.

In one of the cases of dislocation of the index-finger which I reported, some sort of an operation was attempted (the case having passed out of my hands prematurely), probably a subcutaneous cutting of something; the result, however, as I saw it some weeks after, was far from satisfactory, and there was

[2] Backward Dislocation of the Fingers upon the Metacarpus, by E. O. Otis, M.D., Boston Medical and Surgical Journal, September 2, 1886.

[3] Notes on Dislocation of the Thumb, J. E. Kelly, F.R.C.S.I., M.R.I.A., Dublin Journal of Medical Science, May, 1883.

[4] Berliner Klinische Wochenschrift, 1887.

but little motion in the joint. If a dissection had been made as in these two cases, or a subcutaneous section of the glenoid ligament as described in my paper, before referred to, probably the same happy result would have been obtained, as in these cases. I would like to ask Dr. Harrington if he saw anything of the glenoid ligament in his case?

Dr. Harrington: I did not. The opening I made was small. The phalanx was buried out of sight. The thing which I saw most markedly was the external head of the muscle.

Dr. Otis: In irreducible cases often, at least, with the thumb, and generally if not always with the fingers, the glenoid ligament is torn from its metacarpal attachment, reversed, and spread out over the head of metacarpal bone, forming an inseparable obstacle to the reduction, and all efforts made to this effect, even by backward flexion, only fasten the joint firmer, and there is no possibility of reduction except by operative means.

Dr. Warren illustrated the difficulties of reduction of this dislocation by thrusting his finger through a piece of paper and pushing before it a valve-like fragment. If, in the efforts at reduction, this flap turns in between the bones, it cannot be replaced by taxis and the dislocation can only be reduced by cutting down and pulling out this fragment from between the bones.

Dr. F. S. Watson then read a paper entitled

A COMPARISON OF GRADUAL DILATATION, DIVULSION, AND INTERNAL AND EXTERNAL URETHROTOMY IN THE TREATMENT OF URETHAL STRICTURE.[5]

Dr. Greenough said: I have listened to Dr. Watson's very complete *résumé* of the statistics and opinions of those best fitted to give evidence on this subject, with great interest. There is only one point to which I would like to refer, and that is, the almost total immunity from relapse, which is claimed by others, if not by him, in internal urethrotomy. I doubt very much whether internal urethrotomy, or any other operation, can be considered, in itself, as an absolute cure for stricture. We have in a urethral stricture a fibrous tissue which when divided, either by divulsion, or cutting, must be replaced by tissue of the same character. I cannot conceive of any operation which will replace the fibrous tissue of an urethral stricture, by healthy mucous membrane. We all of us see cases that have been operated on by internal urethrotomy, which have relapsed, although the operator may not be aware of it. The clear cut of internal urethrotomy probably produces a better result than the tearing of the tissues by divulsion, but I do not believe that any operation can promise a permanent result, without after-treatment. That a stricture can be operated on by internal urethrotomy, divulsion, or any other method, and go from the operating table permanently cured, I doubt, that is to say, unless the treatment by electrolysis of which we are to hear later, is proved to cause an actual absorption of the contractile tissue, which would of course, be a permanent cure.

Dr. Cabot said: I am very much interested in Dr. Watson's paper. It seems to me a very fair statement about the present state of our knowledge in regard to urethral strictures, so far as it applies to the pendulous urethra. In that part of the urethra the stricture almost always involves the mucous membrane to a certain degree, as well as the connective tissue between it and the corpus spongiosum. When the mucous membrane is thus involved and puckered in the stricture, it seems to me that the cutting operation is by far the best. It has very little danger; hæmorrhage is not of very serious importance, and is easily controlled. I have no doubt it often produces cures. That it is as curative as Dr. Otis believes, I think almost no other man would claim.

In regard to the treatment of deep strictures, I may say that I am not yet converted to the opinion expressed by Dr. Watson, and quoted as expressed by Keyes. It seems to me that there are a great many strictures in the deep urethra, for which the external urethrotomy seems an absurdly grave operation. It has happened to me — I have no doubt it has happened to every one operating by divulsion — to meet with a stricture so tight that it is with the greatest difficulty that the finest filiform bougie can be gotten through it, where, if we finally get a divulsing instrument in, the first wedge driven through the stricture goes through with perfect ease. It is extraordinary with what ease it goes, and immediately the stricture vanishes.

If you then pass sounds, perhaps four, five, or six sizes larger than the divulsing instrument, they meet with no resistance. In short the stricture consisted of a little fibrous cord, surrounding the urethra, which was broken by the divulsion, and done away with. In a case of that sort (and some of these cases have seemed before operation to be very tight, difficult structures), the divulsing operation is the best one. By subsequently passing large sounds the hope of a permanent result is very good.

One reason why divulsion has not had as good results as other operations, is that advocates of divulsion were not advocates of large sounds; whereas those operating by internal urethotomy were advocates of large sounds, and stretched the urethra during the process of healing. The old operations were followed by sounds up to about 12 English — absurdly inadequate, according to our present ideas. It happened to me the other day to see a urethra about twelve or fourteen days after divulsion. The patient died from purulent peritonitis, starting from some trouble about the gall-bladder, as Dr. Fitz established by post-mortem examination. The seat of the stricture was not torn in any way. The urethral mucous membrane was smooth, and apparently had not been lacerated in the least. The stricture had been in the peri-urethral tissue, and had been ruptured with so little injury to the mucous membrane that all traces had disappeared in fourteen days. That is the only case where I have had the opportunity of examining the urethra soon after divulsion. It did not seem to indicate that the damage is so serious in these cases as has been imagined. In these deep strictures in the softer parts, I don't think the tearing is so severe as has been represented.

In regard to the external urethrotomy, it seems to me that that is a first-rate operation, but somewhat serious for the milder strictures in the perineum. I have seen fistula follow the operation in one or two cases. In one case the fistula is a permanent one. It troubles the man very little. By crossing his legs he can pass water without leakage, although there is a decided opening into the urethra.

[5] See page 617 of the Journal.

In a case of perineal operation for division of a bar at the neck of the bladder, I have seen a persistent fistula for five or six months. That case has gone out of my observation, so that I cannot say that it existed longer. I think that the danger of fistula is somewhat greater than the gentleman advocating that operation (Dr. McBurney) stated.

DR. POST: To decide absolutely what is the best course to pursue can only be determined by knowing what course gives most lasting results. We have not at present the data to determine that point, perhaps we never shall have. But it does seem to me that in discussing the subject the matter of gradual dilatation is not given the importance that it ought to have. Whatever operative procedures we decide upon, there must be a very large number of strictures that must be treated by gradual dilatation, either because our patient is in such a condition physicially that we ourselves are unwilling to operate, or because he is so situated that he is unwilling to give up even a few days. And I am fully convinced in my own mind that a great many strictures do wonderfully well for a long series of years after they have been thoroughly dilated by gradual dilatation, by the use of bougies in the old-fashioned method. But the same thing must be said of gradual dilatation that has just been said in regard to divulsion. Not long ago the rule was laid down as a positive one that a dilatation that was carried up to No. 12 English was all-sufficient; that was the size of the urethra. If the patient is treated nowadays by gradual dilatation the same size of urethra should be attained by that method as is sought by internal urethrotomy or divulsion, and when it is carried up to that size, I am sure that the retraction, in favorable cases of course, is much longer in taking place — very much longer — than when the surgeon is satisfied with the size of No. 11 or 12 English.

I don't wish to be considered an advocate of gradual dilatation alone; I simply wish to say that it must be resorted to in the great number of cases, and it seems to me that there is something more to be said in its favor than the paper would seem to indicate. There will always be found a large number of cases that for some reason or other, must be treated by the other more distinctly operative methods, and in the choice of operative procedure, I am practically in accord with the reader.

DR. TILDEN: In looking over Reybard's first pamphlet upon the subject of internal urethrotomy, published in the year 1833, I found that a certain Monsieur Turquet, had once ventured to use a cutting instrument in the urethra for the cure of stricture, and in consequence, had been condemned by the Faculty of Medicine in Paris, as unworthy to practice medicine "*propter temeritutem imprudentiam et ignorantiam.*" The evidence upon the subject to-day as presented by Dr. Watson's paper, would, I think, acquit Monsieur Turquet of any such charge. My own experience with the operation has been comparatively slight, but so far as it goes it has been favorable. I have eighteen cases upon my books, two of which were operated upon by Dr. Morse. Of these cases, only four have been seen again at a long enough period after the operation, to justify any conclusion as to permanence of result. Of these four cases, two were seen two years after the operation, one four years and one five years afterwards. In one instance, two years after the operation there was found to be recontraction, in the other three cases there was no evidence of any recontraction whatever. In regard to strictures of the deep urethra, I have nearly always been able to get along very satisfactorily with gradual dilatation. I have been obliged to cut deep strictures in three instances, and one of these cases was the only one in which I have experienced any serious trouble. The patient was an old man, an unfavorable subject for any operation. He had enlarged prostate and small deep strictures of many years' standing. After the operation he had repeated chills, and rises of temperature accompanied by great prostration and by partial suppression of urine lasting thirty-six hours. He eventually recovered, however. In none of my cases has there ever been hæmorrhage to any extent, and only in my earlier cases has there been any chill or rise of temperature. During the last three years, and since I have washed out the urethra immediately after the operation with a solution of corrosive sublimate, there has been no rise of temperature in any of my cases. One or two words about the technique of the operation may not be out of place. The two most important conditions to be fulfilled in doing the operation in order to secure its best results are, *first*, to entirely divide the strictures which are cut, and, *secondly*, to so manage the wound made by the operation that it may heal with as little inflammation as possible. With regard to the first point, the common cause of early recontractions of stricture, after internal urethrotomy, is insufficient cutting, and Sir Henry Thompson has remarked that he had had often occasion to regret not cutting deeply enough, but never to regret cutting too deeply. The first thing to do then is to cut through the strictures. As to the second point, of course it is impossible that there should be no urethral inflammation at all after urethrotomy, but it should be restricted as much as possible, for this reason. The wound made by the operation, heals over from the edges and becomes covered with a thin supple layer of connective tissue, distinct from the tough connective tissue of which the stricture is formed. This thin layer of connective tissue is let into the strictured portion of the urethra like a "gore" so to speak, and in this way the calibre of the urethra is enlarged at the point of stricture. It is easy to see that if much inflammation attends the healing of the wound that a different and undesirable sort of cicatrix may result. If I remember aright, Dr. Shakespeare has examined, microscopically, this thin layer of connective tissue which results from the proper healing of the wound of the mucous membrane, made in urethrotomy, and has found that there is in it a large proportion of elastic fibres much larger than in cicatrices of the skin for instance. Any urethral discharge which may exist, should always be reduced to a minimum before operating, perfectly aseptic instruments should be used, and after the operation nothing should be introduced into the urethra, except the smooth conical steel sounds which are necessary to ensure a proper healing of the wound, and except the irrigator used to wash out the urethra with corrosive sublimate immediately after the operation, which I think is a good plan. With regard to divulsion, I have had no personal experience, but from what I know of the experience and opinion of others, I should prefer internal or external urethrotomy or gradual dilatation in any case to divulsion.

Dr. Newell: I should like to say in connection with this subject in the first place, that I think Dr. Watson's paper very interesting and valuable, because it shows that since the technique of this operation has been understood, it is clearly demonstrated that whatever its advantages may be, it is certainly not more dangerous than other operations. In the "German Surgery," which so far as I know, is the best surgical work extant to-day, the forty-ninth volume is entirely devoted to the subject of stricture. The point made there which shows the difference between gradual dilatation and all other treatments, is this: Any treatment of the urethra by divulsion or cutting adds a cicatrix to the already existing organized exudation of lymph. The more this has become organized the more dense the stricture is.

I do not exactly understand why, if, as advocates of gradual dilatation claim, you can bring your band of organized lymph up to the desired calibre, and produce more or less absorption by the passage of sounds, the stricture is not cured without the addition of a cicatrix. It seems to me that if you are going to add a cicatrix, the cutting operation is the proper way to do it.

Perhaps Dr. Watson can tell why it is that if you bring a stricture up to the proper calibre with dilatation, you cannot keep it there. I think Professor Dittel claims that no stricture is ever permanently cured. In about twenty years the contraction untreated recurs anyway. I think it necessary to follow the course of strictures twenty years before we are justified in saying that they are cured. If we divide the web of the fingers with a knife, every one knows that there is a wide separation permitted by such a wound, but we know equally well that it is an absolutely certain fact that in the course of time the fingers will come back to exactly the same place. I don't know how cicatricial tissue in one place, differs much from that in another.

Dr. Greenough: Dr. Newell has brought out exactly what I referred to in the few remarks I made at the opening. What Dr. Tilden said interested me very much, but I would like to ask him how we know that the cicatrix which is formed in the healing of the cut is thinner and less fibrous than the original cicatricial tissue.

Dr. Tilden: It has been shown by autopsies.

Dr. Greenough: As we all know, strictures, excepting traumatic ones, are the result of the healing of a granular condition of the urethral mucous membrane. Exactly the same condition is seen by the oculists in old cases of granular conjunctivitis, and also chronic inflammatory conditions of the lachrymal ducts, where the same tendency to contract is seen. This tissue is, I believe, the same that we find in cirrhosis of the liver, and elsewhere as the result of chronic inflammatory processes, in cicatrices of the cutis, etc. When this fibrous tissue in the urethra is cut, there are only two ways in which the lesion can heal: either by first intention, that is, coming together and uniting, practically reproducing the condition previous to the operation, or by the process of granulation, which must result in a fibrous tissue of the same character, namely, one whose tendency is to contract.

In the remarks I have made, I have not meant to speak against the operation of internal urethrotomy, but only against the claim that this operation is in itself a radical cure; that a man can be cut, and that is an end of his stricture. That such has not been the results in many cases, I know from personal experience. I believe that after-treatment, in the way of keeping the urethra dilated is necessary to prevent a relapse. The same thing is true, and perhaps even more so, after the treatment by gradual dilatation, which has, however, the advantage of comparative safety.

A mortality of one or two per cent., may not seem great to the hospital surgeon, but take the case of a man in private practice, who is able to attend to his business, and perfectly well, with the exception of a slight gleet; to kill that man would be a serious matter.

Dr. E. W. Cushing: I would like to ask what the mortality is supposed to be, of internal urethrotomy, in private practice. It seems to me that we are to distinguish a little between what is proper to do in a hospital, in cases who are suffering and are going away, perhaps to sea, and other cases, such as Dr. Greenough refers to, in private practice. I think most men would hesitate, if they were comfortably getting along, if any one were to tell them squarely that there is a mortality of one or two per cent. in stricture operations. I would like to know what the danger is in private practice, as distinguished from those old cases which bring up the mortality.

Dr. Watson: In the figures that I quoted, in some of the instances, I believe those of Otis, Weir, Bull, McBurney, in Dr. Tilden's cases and my own, and a number of others, the operation has been largely confined to private patients. I have never operated upon a patient without telling him he had two chances to die in a hundred. Some take it; some do not. Those that do, I operate upon, and those that don't, I dilate if I can.

Dr. Tilden: I would like to ask Dr. Watson what difference there is between the mortality of the French, English, and American cases.

Dr. Watson: The American cases show the better results in the majority of instances. It is not always so. Sir Henry Thompson has 340 cases, with six deaths. Otis says he has done 600 without a death. French cases have a higher mortality than any others.

Dr. Tilden: Dr. Watson's answer to my question brings out a point which is worthy of notice. The French have largely used a urethrotome which cuts upon the floor of the urethra, and such an incision is undesirable because in this way more spongy tissue is opened than by an upward or even by a lateral cut. I think that the practice of cutting upon the floor adds distinctly to the danger of the operation and that if the French statistics be omitted, its mortality would sink to a very low rate. The English use a bulb-pointed instrument, a modification of Civiales's urethrotome with which they cut in whichever direction they please. One advantage of the Otis instrument is that with it one cuts only upon the roof and in suitable cases, with proper care the operation is attended with as little danger as any operation I know.

Dr. Greenough: My own Maisonneuve instrument cuts upon the roof.

Dr. Tilden: All that I have seen cut upon the floor. My own did, and I had it changed.

Dr. Greenough: That would of course be a very serious objection.

DR. TILDEN: When I spoke of the operation to Ultzmann, he complained of the mortality of the operation, and showed me several French plates of enormous cuts upon the floor of the urethra.

DR. WARREN: In estimating the prognosis of these operations, it is well to remember that the cutting operation was in vogue fifty years ago, as the old instruments abundantly testify. The great advance of modern treatment lies in the degrees of dilatation and it is therefore probable that the improved results are due to this element rather than to the choice of a particular method of dividing the stricture.

DR. G. W. ALLEN then reported

FOUR CASES OF URETHRAL STRICTURE TREATED BY ELECTROLYSIS.[6]

DR. TILDEN said: My experience of electrolysis is limited to one case. A very bad urethritis resulted, and, so far as I know, no benefit whatever was derived from the use of the electrolysis.

DR. WATSON: I had one patient come to me who had had electrolysis performed — not by the gentlemen who have just spoken — where there was precisely the same appearance as that Dr. Tilden describes, and he had a chill in addition. Another one came from Dr. Allen. It is a rather significant fact that no practitioner or specialist of eminence has adopted this treatment after trial.

DR. KNAPP: I should think that Dr. Tilden's case of urethritis might be explained by the electrode. It seems to me that there is opportunity in these electrodes, which are made of hard rubber and metal? for dirt and germs to collect. It would be the best thing in the world to set up a urethritis.

DR. TILDEN: The electrode was brand new and had never been used before.

DR. PARKS: I believe nothing has been said about a method of rapid, gradual dilatation. Prof. Gross used to practice that method, but I don't know whether it is used at all now.

DR. WATSON: It may be stated that rapid, gradual dilatation is in the majority of cases, a divulsion. If the stricture is not divulsed, the method remains dilatation, only that it is accomplished at one sitting; this is sometimes possible, in strictures that yield readily without being split. Some operators habitually perform divulsion in this way. I have seen the late Dr. Charles Homans and Dr. Fifield do the operation a good many times; and have occasionally done it myself.

What Dr. Newell said seemed to me to be very pertinent about the length of time, although I don't see why twenty years should be set, because that is an arbitrary limit. Nevertheless, until after a long time no criterion can be set up. In regard to the question of why you cannot produce permanent cures by dilatation, there are two answers: one is that so far as is known, except in the beginning strictures, no absorption of connective tissue takes place under dilatation; and practical experience is that there are very few people who claim cures, no matter how far the dilatation is carried or how long continued.

DR. NEWELL: I said twenty years, because it is claimed that after twenty years there have been no untreated cases among those observed, that have not returned.

DR. WATSON: In regard to the remark of Dr. Greenough about scars, I think there are one or two points to be considered. One is that so far as we know a linear cut in the urethra, *per se*, does not produce a stricture. That point has been experimentally tried, especially with dogs, and that result discovered, so far as animals are concerned. We sometimes see it also in exploration of the bladder by external urethrotomy, for example, in the human subject.

In regard to dilatation, perhaps Dr. Post misunderstood me a little. The first quarter of the paper was wholly devoted to dilatation. My experience is larger in that than in any other procedure; certainly five times as large. I do not wish to be misunderstood as not advocating dilatation where it is the only operation you have the choice of performing. I would advocate it always in the deep urethra, unless the stricture is intractable to dilatation, or the patient shows constitutional disturbance. Dr. Cabot said that he thought external urethrotomy should not be done for mild strictures in the deep urethra. I do not wish to imply that it should be so done, but merely offer the suggestion it might be done with better results if it were performed earlier, than is the custom, and not reserved for the emergency or desperate cases alone.

DR. NEWELL showed a pair of

ANTISEPTIC HÆMOSTATIC FORCEPS,

made by Codman & Shurtleff. They had been constructed with special reference to cleanliness and were perfectly smooth throughout. The catch, which is that so much used on purses, can also be attached to ordinary forceps.

Recent Literature.

The Curability of Insanity and the Individualized Treatment of the Insane. By JOHN S. BUTLER, M.D., Hartford, Conn. New York and London: G. P. Putnam's Sons. 1887.

This little book of forty-eight pages by one of the oldest insane-hospital superintendents living, is well worth reading as a record of more than fifty years experience in the care of the insane.

Its tone is cheerful and hopeful, and it should be read by the gloomy misanthropes who believe that insanity is practically an incurable disease.

A number of interesting cases are told in detail in the foot-notes.

The Modern Treatment of Diseases of the Heart. Part II. Diseases of the Aorta. By PROF. DUJARDIN-BEAUMETZ. Translated from the Fourth French edition by E. P. Hurd, M.D. Small quarto. pp. 181, 316. Detroit: George S. Davis. 1887.

This neat little volume — the fourth in the Physician's Leisure Library for the present year — is devoted to the treatment of diseases of the aorta, or rather to the chief disease of the aorta — aneurism. The writer begins by considering the treatment formerly considered the only one — Valsalva's method of starvation — and then considers the various methods of treatment that have risen since, compression, injections of ergotine, ice, external galvanization, acetate of lead internally, and iodide of potassium. Of these the only methods that have given good results are compression in abdominal aneurism, and ice and

iodide of potassium, and the results of treatment, even with these, are far from encouraging. In the second chapter the writer speaks of the various operative measures to procure coagulation in the sac, such as acupuncture, and the insertion of wire or horse-hair, and then comes to the chief method of treatment, to which the rest of the work is devoted, the production of coagula in the sac by electrolysis. It is too early to decide whether aneurism of the aorta can be cured by electrolysis, no case has yet been reported, but this treatment is certainly the most promising. Other forms of treatment have thus far proved of little avail; electrolysis has been shown to produce coagula in the sac, in certain cases it has succeeded in relieving for a time the distressing and urgent symptoms, and probably in prolonging life. More is to be hoped from it than from any other form of treatment now in vogue, and this little volume will be of service in widening our knowledge as to its use. It is needless to say that the translation is well done, and Dr. Hurd has also done the profession a service in adding a number of valuable notes.

The Principles of Antiseptic Methods Applied to Obstetric Practice. By DR. PAUL BAR. Translated by Henry D. Fry, M.D. 8vo. pp. 175. Philadelphia: P. Blakiston, Son & Co. 1887.

This book deserves to be read by all who practice obstetrics, especially by those ultra-conservatives who meet every advocate of antisepticism with the query, "What use have we for your antiseptic methods? We do not meet with puerperal fever; our patients always recover."

The author has traversed the subject very fully; and the translator, by occasional notes, has made some valuable additions from American authorities. The relation of the germ theory to the puerperium is carefully considered, the relative value of the various antiseptic agents is discussed in detail, and there is a convincing chapter on the influence of antiseptics on puerperal epidemics in European hospitals. After the chapters on hygiene of the puerperium and the application of antisepsis during labor and the lying-in period, there follow chapters on antisepsis in catheterization, rupture of the uterus, and in the Cæsarean operation. In an appendix the treatment of the fœtal umbilicus and the prophylaxis of ophthalmia neonatorum receive satisfactory consideration. Throughout the book there are profuse references to authorities, yet the reader is never left in doubt as to the opinions of the author. Without prejudice, and without indifference to the labors of others, one may justly say that this work adds still another stone to the monument of Semmelweiss.

—Dr. Blanc has, according to the *London Medical Record*, carried out a hundred observations on the influence of ergotine on involution of the uterus. The preparation employed was the Yvon solution of ergotine injected hypodermically, and the results were controlled by both external and internal measurements. During the ten days following delivery in healthy women after normal labor, he found that the process of involution did not take place more rapidly in the women to whom ergotine was administered than in those left to nature, and concludes that ergotine is without effect on uterine involution.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, DECEMBER 29, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

ANNUS MEDICUS, MDCCCLXXXVII.

EPIDEMIOLOGY.

AT the beginning of the year cholera existed in South America, having been brought by ship from Italy. The disease was most prevalent at Rosario, a sea-port some two hundred miles from Buenos Ayres. It also was present in various parts of Austria-Hungary, in the earlier months of the year, but remained quiescent until the last of March, when it made its reappearance to a moderate degree at Buda-Pesth.

An outbreak of cholera appeared in the spring at Tonquin, which was promptly met by the French sanitary authorities, and which did not affect any but the native population, and these not to an alarming extent after the first. At Peshawur, in India, there were three hundred deaths from cholera in July. In northern India the disease raged extensively, there being seventy thousand deaths (one per cent. of the population), in the north-western provinces in June and July.

It is, however, in Southern Europe that its progress and history have, during the year, chiefly attracted the attention of American physicians. Here cholera became epidemic to a mild degree in March, the centre of the disease being for three months or more the eastern coast of Sicily. The town of Catania had up to July 1st, about two hundred cases with one hundred and forty deaths. Some cases also occurred in Messina and other towns, and also in the island of Sardinia. Early in July it broke out at Rocella, in Calabria, having, probably, been conveyed thither from Messina, or possibly Sardinia.

After the first of July the disease increased in frequency in the Sicilian towns, still having its maximum of violence at Catania. Early in August, it appeared at Malta and at Resina, in the Bay of Naples, also gradually increasing in a number of towns on the Calabrian coast. Numerous cases appeared at Naples, and in the province of Capua. September 4th, two cases were reported at Rome.

During September, the disease increased in southern Italy and Sicily, not only in the towns previously affected, but sporadically, here and there, including Rome. At Naples, the deaths in the middle of September, averaged five or six a day. In Sicily the increase was greater; at Messina the deaths averaged fifty-five a day. The type of the disease at Messina was fulminant, death sometimes occurring within an hour of the attack. From about the middle of October the disease rapidly declined.

September 23d, the Steamship *Alesia* of the Fabian line, from Marseilles, arrived at New York with eight cases of cholera aboard. These were doubtless taken on at Naples, among three hundred passengers who embarked there, and two of whom were sick at the time of embarking. A third case developed September 13th, four died on the voyage. The passengers and crew were quarantined at Hoffmann's Island, and though fifteen or more patients died there, the disease did not obtain any foothold. Soon after the *Alesia*, the *Britannia* and the *Independente*, arrived, the former bringing actual, and the latter suspicious cases, but the passengers of the latter were but briefly detained and those of the *Britannia* were allowed to come up to the upper quarantine; yet, despite these facts, and the unprepared state in which the quarantine station was found by the emergency of the *Alesia*, the disease was stopped on the threshold, and our greatest danger during the year from Asiatic cholera passed over, leaving us unscathed.

Yellow fever appeared at Key West, Florida, in June, there being thirty-one cases with eleven deaths in the first eighteen days of that month. On the 15th of July one case occurred at Egmont Key, Florida, a refuge station, In August and September, the focus of the disease shifted to Tampa, where in the ten days, October 14th to October 24th, one hundred new cases developed with fifteen deaths. The United States Revenue Hospital Bureau established at Tampa a hospital and brought thither a number of acclimated nurses from Savannah. During the last weeks the disease has practically died out.

Scarlet fever has been specially prevalent in Boston and vicinity during the last two or three months of the year, the number of deaths from this cause in Boston, rising some weeks to seventeen or more, out of totals of reported cases amounting to seventy and over. The Boston Board of Health has on this account adopted the rule of fixing a red card of warning to all houses in which cases of the disease exist.

The College of Physicians of Philadelphia celebrated January 2d, the centennial anniversary of its oganization, with addresses by Dr. S. Weir Mitchell, President of the College and Dr. DaCosta, a banquet, and the bestowal of honorary membership on some of the numerous guests who were present from other cities.

Among the cases appealing to the hearts of physicians as well as to their professional interest, has been that of the Crown Prince, Frederick William, of Germany. About a year ago the Prince began to suffer from hoarseness, and in March his physician discovered on the left vocal cord a sessile warty growth which was touched with the electro-cautery and reduced in size. It recurred, and May 21st, Dr. Morell Mackenzie, of London, excised a portion of it, which was examined by Virchow and pronounced a pachydermia verrucosa and not of cancerous nature. Further portions of the growth were removed by Dr. Mackenzie at subsequent times, and the prognosis given was good, the condition of the patient improving as the pieces of the growth were removed, and the galvano-cautery was subsequently applied. During the summer the patient visited England, and in the Scottish Highlands, after the subsidence of the congestion left after the operation, regained voice and spirits, though there remained a tendency to catarrhal congestion and relaxation. There was slight but fugitive thickening of the posterior end of the left vocal cord once or twice. September 14th a thickening three by five millimetres in dimension was seen, one-half inch below the centre of the left vocal cord, and not as will be noted, at the site of the original tumor. This ominous growth has continued, on the whole, to increase, and November 3d, it was a centimeter in diameter and had ulcerated. The unfavorable result of the clinical history, of course outweighs the verdict of the earlier pathological examination, (which, it should be said, was made upon a very small bit of tissue), and the doom of the patient seems to be sealed.

The Hydrophobia Commission appointed by the British Government to investigate the work and claims of Pasteur rendered their report early in the summer, after a delay commensurate with the magnitude of their labors. Three of the members, Sir Henry Roscoe, Dr. Burdon Sanderson, and Dr. Lauder Brunton, visited Paris, and a fourth, Mr. Victor Horseley, conducted experiments with virus brought back by these three, while the remaining four Sirs James Paget, Joseph Lister, and Drs. Quain and Fleming, made up their opinion on the evidence collected and presented by the rest. The report rendered was favorable to the claims of Pasteur, and was to the effect that inoculation with the attenuated virus of rabies confers an immunity from the disease; it further denies that Pasteur's inoculations have been the cause of death in those cases where there has been an unfavorable result. Meantime, there has been in the aggregate a considerable number of deaths after Pasteur's inoculations, though that proportion is small, *provided* all the persons inoculated would otherwise have had rabies. On that *proviso* hangs, as before, the whole question.

First in point of time and of interest, if not of value, among the therapeutic innovations of the year, came the Bergeon treatment of chronic lung diseases by the rectal injection of gases, notably sulphuretted hydrogen. Announced by its discoverer at the close of 1886, its trial in this country began with the new year. Welcomed, as is everything that gives

any promise of immunity from so grave a disease as phthisis, it was tried pretty generally, only to disappoint. Some trifling amelioration of symptoms, such as excessive expectoration, harassing cough, and occasionally a slight gain in flesh, were observed in a few cases, but the bacilli neither disappeared nor diminished sensibly in numbers, and the fatal march of the disease remained in general unchecked.

Pneumatic differentiation by the aid of the cabinet, while less heard of during the year than the Bergeon treatment, has survived the downfall of the latter treatment, and seems to have held its own as, at times, a valuable aid in treating early cases of phthisis when change of climate is unavailable.

Our French brethren have been playing with hypnotism to a very considerable degree. It is an edged tool which in non-medical hands and possibly even when controlled by professional men, is capable of doing mischief. The performances with hysteric women at the Salpêtrière are not calculated to inspire the therapeutist with hope, though it is claimed that attacks of hysteria have been by this agency postponed for months. Whether the remedy is better than the disease, is not quite clear. Just at present the craze is taking the form of "suggestion" of therapeutic aid to hypnotized patients, though the application to the body of corked bottles containing various drugs, or no drugs at all. The government has very properly restricted the position of hypnotism outside of the medical profession, and there may be those who think it would not have been amiss to extend the restriction a little further.

One positive therapeutic gain of the year is the discovery of the analgesic effects of the antithermics, antipyrine and antifebrin, in neuralgic and other pains, where they are often found to replace morphia, without the unpleasant effects of that drug.

Of other pharmaceutical novelties of the year we may refer to saccharine, a compound of certainly great sweetening power, whose chemical name is equally strong, namely, anhydroörthosulphamidobenzoic acid. Gleditschine, or stenocarpine, heralded as of powers superior to cocaine, obtained considerable attention at its first presentation to the profession, but was very soon discovered to be an arrant fraud, being itself nothing more nor less than a solution with an appropriate preservative of cocaine hydrochloride.

The Medical Congress, begotten of the American Medical profession, but "fathered" by the American Medical Association, after a stormy gestation of three years, threatened often with abortion, came to the birth last September. The 2,700 enrolled visitors, *ex facto* and *ex scripto*; the 150 visitors brought over the sea; the long lists of vice-presidents and the vacant chairs reserved for them; the papers, good and bad; the scant social cheer of a capital out of season; and lastly the flow of champagne, certified on oath to have been Mumm's own, and to have been bought with a price — are they not all written in the pages of the remittent daily Medical Journal?

It was a large meeting; and if hardly an "international episode," it yet reflects credit on the perseverance of the gentlemen of the South and West who organized and chiefly attended it.

Of the stated established lectures on medical subjects to which readers turn for the latest and soundest expression of medical science on the topics of which they treat, may be mentioned the following:

The Harveian Lectures on "Cancer of the Uterus," by J. Williams, M.D., London, F.R.C.P.; the Lettsonian Lectures on "Some of the Mental Affections of Childhood and Youth," by J. Langdon Down, M. D., London, F.R.C.S.; the Erasmus Wilson Lectures on "Evolution in Pathology," by J. Bland Sutton, F.R.C.S.; the Hunterian Oration, delivered before the Royal College of Surgeons of England, February 14th, by William S. Savory, F.R.S.; the Gulstonian Lectures on "The Nature of Fever," delivered at the Royal College of Physicians by D. Macalister, M.A., M.D., F.R.C.P.; the Croonian Lectures on "The Pulse," delivered at the Royal College of Physicians by W. H. Broadbent, M.D. F.R.C.P.; the Lumleian Lectures on "The Pathology of Intra-uterine Death," delivered at the Royal College of Physicians by W. O. Priestly M.D., F.R.C.P., LL.D.; the Cavendish Lecture on "A Speedy and sometimes Successful Method of Treating Hay Fever," delivered by Sir Andrew Clark, M.D., F.R.S.; the Bradshawe Lecture on "Pneumothorax," delivered at the Royal College of Physicians by Samuel West, M.D., F.R.C.P.; the Bowman Lecture on "The Relation of Ophthalmic Disease to Certain Normal and Pathological Conditions of the Sexual Organs," delivered before the British Ophthalmological Society by Henry Power, M. D., London, F.R.C.S.; the Morton Lecture on "Cancer and Cancerous Diseases," given at the Royal College of Surgeons of England by Sir James Paget, F.R.C.S. The first course of the Middleton-Goldsmith Lectures under the auspices of the New York Pathological Society was given by Dr. M. Allen Starr, "On Multiple Neuritis and its Relations to Peripheral Neuroses." [These lectures were published in the JOURNAL].

Among the national medical gatherings of importance during the year, we note the following:

The Medical Society of the State of New York held its eighty-first annual meeting at Albany, February 1st to 3d; the Sixth Annual German Medical Congress was held at Wiesbaden, April 13th to 16th, under the presidency of Professor Leyden, of Berlin; the Sixteenth Congress of German Surgeons met at Berlin, April 13th to 16th, Prof. von Volkmann presiding; the American Surgical Association held its annual meeting at Washington, May 11th to 14th; the American Association of Genito-Urinary Surgeons met for the first time at Lakewood, N. J., May 17th and 18th; the American Laryngological Society held its ninth annual meeting at New York, May 26th to 28th; the American Climatological Society

had its fourth annual meeting at Baltimore, May 31st and June 1st; the American Medical Association held its thirty-eighth annual session at Chicago, June 7th to 10th; the second annual meeting of the Association of American Physicians was held at Washington, June 2d and 3d; the thirty-sixth annual meeting of the American Association for the Advancement of Science was held at New York, August 10th to 16th; the National Orthopædic Association met for the first time in New York, early in July; the American Otological Society held its twentieth annual meeting at New London, Conn., July 9th; the American Ophthalmological Society held its twenty-third annual meeting at New London, July 20th and 21st; the American Neurological Association held its thirteenth annual meeting at Long Branch, July 20th and 21st; the fifty-fifth annual meeting of the British Medical Association was held at Dublin, August 2d to 5th, Dr. Withers Moore presiding; the eleventh annual meeting of the American Dermatological Society occurred at Baltimore, August 31st to September 2d; the Ninth International Medical Congress met at Washington, September 5th to 10th; the American Gynæcological Society held its twelfth annual meeting in New York, September 13th to 15th; the German Congress of Physicians and Surgeons met September 20th to 22d: one of its most important features was the address by Virchow on "Transformismus"; the Sixth International Congress of Hygiene and Dermography met at Vienna in the latter part of September. The importance of this meeting demands for it a word of further mention. The attendance was about 2,400, and the meeting was presided over by the Crown Prince Rudolph, of Austria. Professor Brouardel read a paper on "The Propagation of Typhoid Fever"; Professor Pettenkofer on "The Teaching of Hygiene in the Public Schools and Universities." In a notable discussion on "Cholera and Quarantine," the English delegates, with Pettenkofer, and notably an Italian, Dr. Mosso, of Turin, maintained strongly the uselessness of quarantine, and the importance of putting sole trust in sanitary reform. The seventh meeting of the Congress occurs in London in 1891.

GENERAL NECROLOGY.

While death has been as busy as ever during the year, it is somewhat remarkable that his hand has fallen with special force upon the medical profession in Italy. No other country has suffered so heavy a loss, proportionally to its size, of men of brilliant achievement in this branch of science.

We present briefly a list of the most prominent medical men who have died during the year.

William Perry, M.D., the oldest living graduate of Harvard College, a member of the class of 1811, long a successful practitioner in Exeter, N. H., died January 11, aged ninety-eight years and twenty-one days.

Nicola Gasparri, aged thirty-three, a medical officer of prominence in the Italian army, was killed January 26, while fighting in the ranks in a most desperate encounter at Dogali, between five hundred Italian troops and many thousand Abyssinians. The fight was continued till of the five hundred Italians only eleven remained unwounded.

Francesco Magni, probably the leading ophthalmologist of Italy, died at San Remo, February 2, at the age of fifty-nine. He was made director of the anatomical school at Florence in 1859, and a year later was called to the chair of ophthalmic surgery at Bologne. He subsequently visited the United States, and made a brilliant reputation in many of the northern cities for his diagnostic and operative skill. He was Senator of the Kingdom of Italy 1876, and politically was a Liberal.

Prof. Carl Schroeder, of Berlin, died February 7, at at the age of forty-nine, after a two weeks' illness, from brain fever. He was one of the leading gynæcologists of Europe, and his hospital for women at Berlin attracted crowds of students and patients from all parts of the world. He had written numerous works on this subject, among them his Manual of "Midwifery, including the Pathology of Pregnancy and the Puerperal State," which has been translated into English and widely read. His early death was attributed to overwork.

Jules Béclard, dean of the Faculty of Medicine of Paris, in which he succeeded Professor Vulpian in 1881, died February 16, at the age of sixty-nine. He was author of the "*Traité de Physiologie Humaine*," which was for thirty years the standard work on that subject in France, and which reached seven editions. In 1844 he defeated Claude Bernard in the competition for the assistant professorship of anatomy and physiology, and in 1871, on the death of Longet, became professor of physiology.

Dr. W. S. Little, an eminent Philadelphia oculist, died February 18.

Prof. T. Gaillard, of Paris, a prominent French gynæcologist and obstetrician, died early in the year.

Alexander Porphyryvich Borodin, Professor of Organic Chemistry in the Military Medical Academy of St. Petersburg, died February 28, aged fifty-three.

Luigi Laurenzi, head of the Ospedale della Consolazione in Rome, and a surgeon of renown, died suddenly, in the prime of life, April 5.

Pietro Cipriani, of Florence, eminent in several departments of medicine, and Senator of the Kingdom, died April 5, aged seventy-nine. He was the first occupant of the chair of cutaneous diseases, established in Florence in 1840, and afterward was professor of clinical medicine, succeeding Bufalini.

Dr. James S. Jewell, of Chicago, a founder of the American Neurological Association, Professor of Nervous and Mental Diseases in the Chicago Medical College since 1872, and originator, two years later, of the *Journal of Nervous and Mental Diseases*, died April 18, aged fifty.

Nathaniel Lieberkühn, son of the discoverer of the "follicle," and himself professor of anatomy in Marburg, and an industrious student in subjects connected with development, died in April, aged sixty-five.

Alfred Meadows, M.D., F.R.C.P., at the time of his death physician-accoucheur to St. Mary's Hospital, and previously the holder of many obstetrical positions in connection with other London hospitals, died April 19, aged fifty-five.

Leon Gosselin, surgeon to the Paris Hospitals, professor of surgical pathology (1858), professor of clinical surgery (succeeding Velpeau in 1867), member of the Academy of Sciences, and president of the same, author of many surgical works, perhaps most prominent among them the "Clinique de l'Hôpital de la Charité," died April 29, aged over seventy.

E. T. Caswell, M.D., one of the surgeons to the Rhode Island Hospital, and a well-known practitioner of Providence, R. I., died April 17, aged fifty-four years.

Wilson Fox, M.D., F.R.C.P.L., F.R.S., died in London, May 3, aged fifty-six. He had been a student under Virchow, and in 1861, at the recommendation of the latter, was made Professor of Pathological anatomy in the University College of London. Six years later he became professor of clinical medicine. He was an industrious student and writer on various subjects connected with these departments, especially upon tuberculosis. He wrote the articles in Reynolds's "System of Medicine," on Diseases of the Stomach, and on Pneumonia.

Professor Vulpian, the noted French physiologist, died May 18, aged sixty. Known in his own country as a lecturer, and as dean of the Faculty of Medicine, his chief fame on this side of the water rested upon his writings, which covered almost all the subjects of physiology, and ended with his work, in two volumes, on the "Diseases of the Nervous System."

Dr. E. Darwin Hudson, of New York, formerly Professor of Medicine in the Woman's College of New York, and later a professor of the New York polyclinic, an active worker in medical science, author of a standard work on "Physical Diagnosis," died May 10, aged forty-four.

Karl Friedländer, pathologist, of Berlin, died in May, at the early age of thirty-nine. While he had never held exalted rank in the academic scale, being made professor only a few months before his death, and that without any official chair, he stood in the foremost rank of living pathologists. He discovered in 1882 a coccus which he claimed to be pathognomonic of pneumonia, and which is known to bacteriologists by his name.

Dr. Alexander Gordon, for many years the leading surgeon of Belfast and the north of Ireland, died July 28, aged sixty-nine. He was made professor of surgery at the opening of Queens College, Belfast, in 1849, and held that chair till shortly before his death.

Dr. Andrew Fergus, of Glasgow, a crown representative on the general medical council, President of the Glasgow Philosophical Society, and a practitioner of large experience and repute, died in July, aged sixty-five.

Dr. Gustavus Charles Philip Murray, a leading practitioner of Edinburgh, an original member of the London Obstetrical Society, a voluminous writer on obstetrical subjects, and a visitant to numerous hospitals for diseases of women, died August 7, aged fifty-six.

Adolph Pansch, Professor Extraordinary in the University of Kiel, author of many anatomical observations, a scientific member of the second German expedition to the North Pole (1869-70), was drowned at Kiel, August 14, at the age of forty-six.

Alonzo Clark, M.D., L.L.D., Professor of Physiology and Practical Medicine in the College of Physicians and Surgeons of New York since 1855, died September 13, aged eighty. He had previously held other professional chairs, the first being that of pathology and materia medica in the University of Vermont Medical School. His chief fame was as teacher and consultant rather than as author. He was connected with Bellevue, the New York, and other hospitals, was president of the Medical Society of the State of New York in 1853, and later of the New York Academy of Medicine.

Richard Quain, M.D., F.R.C.S., one of the founders of the London Pathological Society, the editor of Quain's "Dictionary of Medicine," and a well-known writer on medical subjects, died Sept. 16, aged seventy-one. He bequeathed almost the whole of his fortune, amounting to $375,000 to University College, London, "for the promotion . . . of general education in modern languages (especially the English language and composition in that language), and in natural science."

Dr. Gaetano Pini, of Milan, of special prominence as one of the early cremationists, his society of 1876 having been followed by thirty-six others in Italy in the face of bitter opposition from the Roman church, died September 25, aged forty-one. He was also the founder of the Royal Italian Society of Hygiene.

Dr. J. C. Hutchinson, of Brooklyn, long and prominently connected with the Brooklyn Hospital, died in October.

Dr. Jas. A. Gray, of Atlanta, editor of the *Atlanta Medical and Surgical Journal*, died September 7, aged thirty-seven.

Dr. James Knight, Surgeon-in-chief of the Hospital for the Relief of the Ruptured and Crippled in New York, died in October, aged seventy-seven.

Dr. Wm. M. Chamberlain, of New York, of the staff of Charity Hospital, a specialist in the diseases of women, died October 31, aged sixty-one.

Leon Bassereau died at Paris, November 1, at the age of seventy-seven. In 1852 he published the work which definitely settled the fact that there existed a syphilitic and a non-syphilitic chancre. By repeated confrontations of infected and infecting individuals, he was able to formulate the law "That when an individual is attacked by a chancre which is followed by constitutional symptoms, generalization of symptoms is due to the fact that the individual from whom the

infection came was the victim of syphilis." Bassereau was thus the author of the doctrine of dualism.

Dr. Thomas R. Varick, of Jersey City, Visiting Surgeon of St. Francis Hospital, and one of the leading surgeons of New Jersey, died November 23.

Dr. Middleton Goldsmith, of Rutland, Vt., the founder of the Pathological and the Middleton-Goldsmith Lectures, in New York, died November 26, aged sixty-nine. He had been dean of the Kentucky School of Medicine at Louisville, and served as brigade-surgeon in the war. He was deeply interested as might be judged from the foundations above referred to, in the progress of medical science. Shortly before his death, he presented his library to the New York Academy of Medicine.

Sir William R. E. Smart, K.C.B., died on December 2, at the age of seventy. He joined the Royal Navy in 1841. When the Russian war began, and the siege of Sebastopol was determined on, his ship was converted temporarily into a hospital until huts could be erected on shore for the reception of the sick and wounded, who were placed in charge of Dr. Smart. The admirable efficiency of his arrangements, and the zeal, energy, and humanity he invariably displayed in the duties of the hospital, whither all the worst cases were sent from the front, were soon recognized by the eminent naval officers in command, and on their recommendation he obtained from Lord Raglan the rank and privileges of a first-class Staff Army Surgeon. He was an active member of the Epidemiological Society.

Professor Charles Lauger, of Vienna, died on December 8. He was born in 1819, took his degree of M.D. at the University of Prague, was for a time an assistant of Professor Hyrtl, and when that distinguished anatomist died, was elected to the professorship.

Sir George Burrows, Bart., M.D., L.L.D., (Hon.), Cantab., D.C.L., Oxon., was born in 1801. He was a student, and later the son-in-law of Abernethy, and studied under Breschet and Scarpa. He had been physician to St. Bartholemew's Hospital, and had been lecturer on Medical Jurisprudence, and later, in conjunction with Dr. Latham, lecturer on Medicine. In 1862 he was President of the British Medical Association. In 1873 on the death of Sir Henry Holland, he became physician in ordinary to the queen. In 1871 he was elected President of the Royal College of Physicians, holding the office for four years.

NECROLOGY OF THE MASSACHUSETTS MEDICAL SOCIETY, 1887.

Preston Marshall Chase, of Danvers, died January 4, aged fifty-nine.

William Alexander Gordon, of New Bedford, died January 14, aged seventy-eight.

Jones Franklin Wakefield, of Everett, died January 14, aged sixty-two.

Joseph Thomas Odiorne West, of Princeton, died January 28, aged sixty-three.

Silas Emlyn Stone, of Walpole, died January 29, aged forty-eight.

Anthony Bernard Magee, of Lawrence, died January 31, aged thirty-five.

Jonas Augustus Marshall, of Fitchburg, died February 25, aged eighty-six.

John Beveridge Fulton, of East Boston, died March 19, aged fifty-two.

Ashman Hinckley Taylor, of Shelburne Falls, died April 13, aged sixty-four.

John Sydenham Flint, of Roxbury, died April 16, aged sixty-three.

Joshua Vincent Smith, of Melrose, died April 18, aged forty-one.

Gustavus Percival Pratt, of Cohasset, died April 29, aged forty-seven.

Marcus Bloomfield Leonard, of East Boston, died May 6, aged sixty-six.

George Augustus Warren, of Hopkinton, died May 6, aged sixty-eight.

Charles Warren Hackett, of Maplewood, died June, aged thirty-five.

Ebenezer Wade Drake, of Middleboro', died June 28, aged sixty-nine.

John Sullivan Bogg, of Springfield, died July 9, aged thirty-eight.

Charles Eliot Ware, of Boston, died September 3, aged seventy-three.

John Ambrose McArthur, of Lynn, died September 28, aged fifty-seven.

John Odoway French, of Hanover, died September 29.

George Otis Allen, of West Roxbury, died October 3, aged forty-eight.

David McCaire Parker, of Boston, died October 8.

James Wilde, of Duxbury, died October 15, aged seventy-five.

Pierre Le Breton Stickney, of Springfield, died November 5, aged seventy-three.

Charles Edward McGowan, of South Boston, died November 12, aged thirty-six.

James Henry Waterman, of Westfield, died November 23.

Nelson Briggs, of North Arlington, died November 25, aged seventy.

Charles Harrison Spring, of Boston, died December 9, aged fifty-five.

David Dana, of Lawrence, died December 10, aged sixty-four.

John Manchester Smith, of Vineyard Haven, died December, aged sixty-one.

MEDICAL NOTES

NEW YORK.

— An ambulance corps is to be established in the various regiments, batteries, and separate companies of the New York State Militia. For some time past the surgeons and assistant surgeons of the New York and Brooklyn regiments have had the mat-

ter under consideration, and having united upon a plan for the organization of such a corps they have submitted it to Surgeon-General Bryant, who will act upon their recommendations as soon as the necessary order has been issued by the Adjutant-General of the State.

— A burglar in Brooklyn, who was recently wounded in a conflict with the police while escaping, with two companions, after committing a robbery at night, has been identified in rather a curious way. When arrested it was found that his upper jaw was broken and several of the teeth were gone, a circumstance which he explained by stating that he had been assaulted by two men. A detective was sent, however, to the scene of the shooting affair with the police, and he there found a piece of jaw-bone with teeth attached, which exactly fitted the gap discovered in the man's mouth.

Miscellany.

SOME VASO-MOTOR PHENOMENA IN TYPHOID FEVER.

Dr. Angel Money calls attention (*Lancet*, December 3d) to certain vaso-motor phenomena, which he has noted in cases of typhoid and of rheumatic fever. He divides them into classes, as follows: In the first class he places the *spontaneous vaso-motor phenomena*, by which he means those facts which may be witnessed without further irritation or stimulation than attends the mere exposure of a surface of the body or limb on which the observation may be made. If it be the surface of the abdomen, this may be found to be for the most part of a pinkish hue, such as tends to obscure the presence of rose spots, if such be present; but scattered here and there through the red tint, which they mottle, may be seen areas of whiteness, which present a distinct and striking contrast with the general tint, and are, moreover, characterized by varying in distinctness, being whiter or less white at one moment than at the preceding or succeeding moment. If to such a skin, under such circumstances, the additional condition be added of a slight mechanical — electrical or thermal — stimulation, certain further observations may be made, the purport of which he does not pretend to fathom, though it would be easy to offer plenty of hypothetical explanations. It generally happens that the stimulated area or line turns white or ivory-tinted after the lapse of a rather long latent period, variable in different cases and at different times for unascertained reasons, and measurable generally by seconds. The whiteness is not strictly limited to the irritated section, but spreads away from the part stimulated, and in a gradual, decreasing fashion. Moreover, the pallor does not appear abruptly after the period of latency, but the pinkness of the skin gradually gives way to the whiteness, and the changing hue is very perceptible. Thus, both in space and time the phenomenon has a graduation and a duration which are, comparatively speaking, of slow course, and remind one rather of the contraction of smooth, plain, nerveless muscular fibre, than the rapid, sharp contractions of the well-nerved voluntary muscle.

Again frequently, but not always, it will be found that exposure of the skin of the arm and forearm in the same subject presents a contrast with the previously or simultaneously exposed surface of the abdomen, the general tint being white with irregular patches, sometimes streaks, of pink or darker red. When this contrast is evident, and occasionally when there is no such general and spontaneous dissimilarity of appearance, mechanical, and sometimes (? always) electrical and thermic, irritation of the skin of the arm will be followed after a similar, but perhaps generally a trifle shorter, period of latency by the gradual development of the *tache cérébrale* or red streak, having the usual characters of that phenomenon. Sometimes the surface of the arm has a general pink tint on first exposing it to the atmosphere, and this may rapidly change to white, but the color of the written characters thereon may be deep red. The contrast in color may be still more remarkable, even in the same case; the writing may be white on the surface of the abdomen, red on the forearm, white on the legs. He lays considerable stress on the circumstance that the temperature of the skin and of the body is usually high in cases which present these vascular phenomena, and, further, I have most generally observed them in full perfection when the skin has not been perceptibly sweating. But, as proving that neither increased heat nor an especial dryness of the cutaneous tissues is necessary to the production of such phenomena, he observes that he has seen them very well marked in cases of epilepsy and chorea of uncomplicated and afebrile sort. It may be worth placing on record, also, in this connection that the majority of cases in which these observations were made the brain was certainly perturbed in its functions, for delirium was frequently present at some period of the twenty-four hours, mostly at night-time; still his observations were usually made during the day-time, and when the intellect of the patient, to all ordinary modes of investigation, did not seem to be abnormally affected.

Correspondence.

"THE DOCTOR'S WIFE."

Audi Alteram Partem.

Cranberry Meadows, Dec. 23, 1887.

Mr. Editor, — I can keep my peace no longer, but must tell your readers the true story of Dr. Benedick's success. Of course you supposed that no one but doctors would read the letters you have published, and you were glad to let them smile at what they would graciously term the foibles of the doctor's wife; but I fear they do not realize that perhaps they owe more to her than even Dr. Cœlebs would admit in his bluest moment. I really think Dr. Benedick himself was a trifle afraid of hearing a personal opinion on the matter, for I have had difficulty in finding the *Journal* during these past few weeks, and only after a vexatious search has it been discovered at the bottom of a pile of papers which haven't been read for two months. And this leads me to say that, possibly the genial raillery in the first charming letter about the doctor's wife putting the baby with the fit into hot water, and soothing the terrified friends of the man with the broken leg, may have been an unconscious testimony of the writer to a knowledge which was far deeper than he knew.

Perhaps he is like Dr. Benedick, who probably does not know with what zeal his wife picks up scraps of knowledge

from those very books which he innocently supposes are never disturbed except on the rare occasions when he proudly pulls them down to dazzle the eyes of old Dr. Wormwood, whose library is said to consist of a dozen old volumes which have been lying on the top shelf of his closet for fifteen years. The most recent one among them was purchased back in the forties because it gave a description of the only operation the doctor ever performed, which exploit, as he tells of it whenever he has a chance, he very naturally mentions in his letter.

But, perhaps, your wives read more than you think, gentlemen; and perhaps there are some things they hear outside which might be worth a good deal to you. They get information from lips that to you are sealed. Confide in them and, my word for it, you will not be sorry.

True, the wife alone cannot bring success; yet compare these pictures and give your verdict. The patient who calls at Dr. Cœlebs' door is met by a frowsy, sour-faced housekeeper, a look at whom would give anyone the dyspepsia. He is shown into an untidy, dismal room, smelling of cheap tobacco, and fairly littered with instruments suggestive of all manner of tortures. The doctor is patterned after the room. When he emerges to make a call the only button still clinging to his overcoat is half-way down; his unblacked shoes are well calculated to show the knots in his shoe-strings, which will come untied; his beaver shows three years of style, and at least five of decrepitude; and the glove which still sports a button is ripped between the fingers. No one doubts that he knows more than old Gamboge ever did, but when he combats all the old women's theories, which the shrewd old doctor had assiduously nourished all these years, his learning goes for nought. Perhaps it isn't so in other places, but people here in Cranberry Meadows don't hire a doctor to show them how much he knows, but to make them satisfied with themselves.

If some one calls upon Dr. Benedick, a pleasant face greets him at the door, and he feels better already. A patient and sympathetic ear hears his story. Everything is neat and cozy. The doctor is never allowed to go out without a final survey, to see that all is right. A smile puts him in good humor before he leaves, and the reckless way in which he acquiesces in what has been done by the maiden aunt before his arrival, would make his medical instructors hold up their hands in horror; yet the aunt, and with her, the family, are his friends for life.

But there are secondary points. The true secret of success is this: *Dr. Benedick wears a full beard.* The doctor's strength varies diversely with the number of hairs on his face, and inversely with the number of those on his head. When Father Time shall have reaped the harvest from the crown of our neighbor, Dr. Cœlebs, and gathered in the shocks, and shall have raised a new crop on the soil below, now lying fallow, then our friend will be too busy to write plaints to the JOURNAL, because there has not yet been dealt him that winning card which he calls

"THE DOCTOR'S WIFE."

MRS. BENEDICK HAS THE LAST WORD ON THE "DOCTOR'S WIFE."

CRANBERRY MEADOWS, December 26, 1887.

MR. EDITOR,—I noticed for three weeks that the *Medical Journal* was put away so that I could not find it, but I went to the Post Office myself when the last number came and then the whole thing came out, and I have seen your editorial and what Dr. Cœlebs and Dr. Benedick and Dr. Wormwood have to say, and I must say, Mr. Editor, that time must hang pretty heavy on some people's hands. I think Dr. Cœlebs is real mean. I don't know why he wants me to stop going to sewing society just because I'm married. I always have been to sewing society and amusements are not so numerous in the Meadows that one can neglect them. I wonder what he would have said if I had not returned my wedding calls. We do not stand on ceremony here in the Meadows, but we are very particular about wedding calls, and you can't expect us to be *purposely* disagreeable to folks that may be patients, and you can't expect a girl who never had anything in her life to conceal, to learn all at once to hold her tongue. Folks here are interested in me, and of course they ask me questions about the sick people, and of course I have to tell them something. If *somebody* would remember that I don't tell *all* I know, I should think he would be thankful.

It certainly is real hard for a doctor's wife to know just what to say and what to do. Everybody takes it for granted that she knows just where her husband is, and what he said, and just how every patient is doing. It makes me ashamed sometimes when the doctor don't tell me about something, and I have to say I don't know about it. And it seems to me just right that the doctor's wife should be able to tell people about their sick friends. Now when the Prince of Wales and President Garfield were sick, there used to be bulletins from the doctors published in all the newspapers, and when young Bulwhacker was nearly killed, stopping the runaway horse down at the South Meadows, and lay for four weeks so near death that nobody dared speak, and my husband spent most of his time there, and finally pulled him through, people couldn't go four miles twice a day to inquire about him, but they used to come to me and find out what the doctor said, and I kept a list of all of them, and showed it to his poor mother when he was well again. Now wasn't that better than saying I didn't know?

Now that note of Dr. Benedick's is just like him, he is altogether too modest and he likes to make it appear as if it was all Mrs. Gamboge's doings. He always does belittle himself, and if anybody ever needed somebody to stand up for them, he does, and I think it is high time that some one who *knows* and who is *calm* and *reasonable* should correct the wrong statements that have been made.

In the first place, if my husband had showed me his letter before mailing it, I could have set right *one* error. I want it distinctly understood that Aunt Gamboge *never* made up *any* match between me and my husband. She told me often enough that if I *must* have one of them she knew which she should choose, but I was just throwing myself away to marry either of them and that is all the match-making she did. Perhaps if my choice had been different your correspondence would have been different too. When the doctor married me it was because he wanted to bad enough to ask me, and I did not say yes the first time either. He *is* doing beautifully in his practice since he married, and Mrs. —— told me only yesterday that he was by all odds the coming doctor of the town, and our mare is not spavined, whatever that hateful old Wormwood (gall and wormwood, *folks who like a joke*, call him) may say. It is just because my husband had to drive her so much that she went lame, and we wouldn't have had to give our note for him if we hadn't got him just the same time that the baby was coming. Fuller Wormwood never would have known about the note anyway if he hadn't been looking around for some way to invest his scrapings and scrimpings and bought it. If there is anybody that is just hateful, it is that old Wormwood. Everybody knows that the only thing that ever got him along at all was his being so cross and snappy. There are some folks that always think that a doctor doesn't know anything unless he is as savage as a bear. I always did hate an old bachelor that is a doctor. They get crustier and crosser than any other kind of an old bachelor, and they are all bad enough goodness knows, besides *I* think, and there are plenty more think as I do, that it isn't right for an unmarried man to be coming into houses and attending ladies. I should not dare to write this if I did not know where the money was coming from to pay our note.

One curious thing has happened since Cœlebs took to drink. He has really got several good patients by it. They say if he can do anything at all when he is drunk, "what must he be when he is sober!" And the women of the temperance society have taken him up to try to reform him, "it is such a pity to see a man with such a brain

ruining himself with liquor," so that he is altogether doing better than ever before.

Now I think I ought to tell you about that "case," though I should not *dare* to if I was not a doctor's wife, but I guess I must be the only one left that knows about it unless Aunty Gamboge does, and I really feel that I *ought* to tell. Well grandpa went back to Uncle Gamboge and sorry enough he was he ever left him; for after the operation something was so bad that he was always taking medicine and every once in a while Uncle G. had to go out to see him and they used to have just *awful* times.

Respectfully yours,

BEATRICE JANE BENEDICK.

P. S. — If my husband should go down to the Legislature next winter couldn't you get him a place on the Board of Lunacy and Charity? He took a patient over to Taunton once, and the doctor there showed him round, and we have been reading up about *alcoholism*, so he is well up in that part of the subject. As for the charity, there are lots of such cases among the factory people. I hear board is high in Boston, and if you could get him into such a place it would be a great help. I hope you will be sure and keep your promise and not let anybody else write anything more.

B. J. B.

ADVERTISING CHAMPAGNE.

BOSTON, December 26, 1887.

MR. EDITOR, — I have received a few circular letters containing letters of endorsement from the chairmen of committees and officers of the International Medical Congress at Washington, and I presume that other physicians may have had similar advertisements. The least that can be said about these endorsements is the want of dignity in lending apparent support to this means of advertising commercial firms. Though the enclosed refers to a brand of champagne, I have received other circulars of the same character and endorsements of medicinal trade compounds.

I hope that other physicians will forward these advertisements to the medical journals, that we may know our professional colleagues who appear in this public capacity.

Yours respectfully,

MODESTAS.

MATERNAL IMPRESSIONS ON THE FŒTUS IN UTERO.

NEWPORT, R. I., December 16, 1887.

MR. EDITOR, — A few days since I attended Mrs. C., a robust Swedish woman during an easy and natural labor. Before leaving the house I examined the child, and found that it seemed to be totally blind. As a matter of curiosity, I inquired of one of their intimate friends if any thing had happened to bring this about, and learned that they had another girl about four years old who had remarkably beautiful eyes and of whom the mother was exceedingly proud, and during her pregnancy she would frequently in private and before visitors cause the child to close her eyes, and then tell her she had no eyes, they were gone, remarking also what a sad case that would be.

I remember her also asking at once after the birth of her child about the condition of the eyes, if they were perfect, etc. Very truly yours, T. A. KENEFICK, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 17, 1887.

Deaths reported 2,316: under five years of age 773; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 407, acute lung diseases 338, consumption 311, diphtheria and croup, 201, scarlet fever 48, diarrhœal diseases 47, typhoid fever 43, malarial fever 21, measles 14, whooping-cough 10, erysipelas 10, puerperal fever seven, cerebro-spinal meningitis six. From malarial fever, New York and Brooklyn seven each, New Orleans five, Baltimore and Nashville one each. From typhoid fever, Pittsburgh seventeen, Philadelphia, and Baltimore six each, New York four, Boston and District of Columbia three each, Nashville two, Brooklyn and Charleston one each. From measles, New York six, Baltimore four, District of Columbia and Milwaukee two each. From erysipelas New York five, Boston three, Baltimore two. From whooping-cough, New York, Philadelphia and District of Columbia two each, Boston and Milwaukee one each. From puerperal fever, Milwaukee two, New York, Philadelphia, Boston, Cambridge and Gloucester one each. From cerebro-spinal meningitis, New York three, Philadelphia, Milwaukee and Fall River one each.

In the 21 cities and greater towns of Massachusetts, with an estimated population of 1,012,974, the total death-rate for the week was 21.14 against 21.50 and 22.08 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,244,099, for the week ending December 3d, the death-rate was 22.2. Deaths reported 3,978: infants under one year of age 885; scarlet fever 108, whooping-cough 96, fever 59, diphtheria 48, measles 69, diarrhœa 37, small-pox (Sheffield 25, Bristol one) 26.

The death-rates ranged from 15.5 in Brighton to 35.6 in Newcastle-on-Tyne; Birmingham 21.1; Blackburn 30.4; Halifax 23.1: Hull 16.2; Leeds 20.0; Liverpool 22.5; London 21.1; Manchester 26.3; Nottingham 24.4; Sheffield 29.2; Sunderland 17.3.

In Edinburgh —; Glasgow —; Dublin 35.0.

The meteorological record for the week ending December 17, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Dec. 17, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.
